1 Introduction

1.1 Overview

TGS-NOPEC Geophysical Company Pty Ltd (**TGS**) propose undertaking a three-dimensional (**3D**) multi-client (**MC**) marine seismic survey (**MSS**) in the Otway Basin, in Commonwealth waters offshore from Victoria (**VIC**), Tasmania (**TAS**) and South Australia. Hereafter, these activities will be referred to as the **Otway Basin 3D MC MSS.**

The Otway Basin 3D MC MSS provided for in this Environment Plan (**EP**) will be undertaken within the Operation Area defined in **Section 3.2.1** and will be undertaken in discrete phases depending upon future petroleum acreage releases in the region and petroleum client interest. This EP allows 3D MSS phases to be undertaken during a 5-year period, between 1 October 2023 (subject to acceptance of this EP by The National Offshore Petroleum Safety and Environmental Management Authority (**NOPSEMA**)) and 30 September 2027. A maximum of 200 days will be acquired each year, with a total maximum of 400 days for the entire survey.

This EP has been prepared to ensure the Otway Basin 3D MC MSS is planned and undertaken in accordance with TGS' Quality, Health, Safety and Environment Policy (**QHSE Policy**), which is discussed further in **Section 1.6**, along with the regulatory requirements of the Offshore Petroleum and *Greenhouse Gas Storage Act 2006* (**OPGGS Act**) and the associated *Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2009* (the **Environment Regulations**).

1.2 Purpose and Objectives

In accordance with the requirements of the Environment Regulations, the purpose of this EP is to demonstrate that the Otway Basin 3D MC MSS will be undertaken in a manner that is consistent with the principles of Ecologically Sustainable Development (**ESD**). This includes assessing the potential risks and impacts to the different receptors within the receiving environment and relevant persons/marine users that utilise the area. This assessment considers the controls measures and operational procedures proposed to be implemented in order to reduce the potential adverse environmental impacts and risks associated with the Otway Basin 3D MC MSS to As Low As Reasonably Practicable (**ALARP**) and to **Acceptable Levels**. Environmental performance standards (**EPS**) have also been developed as part of this EP to measure the performance of the controls measures and operational measures that will be implemented during the Otway Basin 3D MC MSS.

The objective of the proposed Otway Basin 3D MC MSS is to provide an 3D data coverage and improved subsurface imaging within the Deep Water Otway Basin. Historically the primary exploration focus, and success, has been on the continental shelf offshore portion of the Otway Basin. The new 3D data (which is located outboard from the continental shelf) will provide an improved understanding of the subsurface, which to-date has been limited to sparse 2D data coverage. Ultimately the new data will provide improved confidence in mapping major geological units aiding in the identification and de-risking of petroleum prospectively across the Seismic Survey area.

1.3 Scope of the Environment Plan

The scope of this EP addresses the petroleum activity—a marine seismic survey—and associated activities as described in **Section 3**.

In particular, the scope of this EP covers phases of 3D seismic data acquisition and associated line turns, run-ins, run-outs, seismic testing and support activities within the defined Operational Area (**OA**) (**Figure 1**). The timeframe of this EP is from 1 October 2023 to 30 September 2027.

The petroleum activity is defined as commencing at the point when the Seismic Vessel is within the defined OA and the source is deployed, until the Seismic Vessel has retrieved the seismic source and departed from the OA, following completion of each survey phase. The scope of this EP does not include the periods when the Seismic Vessel and support vessels are not engaged in the Otway Basin 3D MC MSS or associated activities, such as during maintenance activities outside of the OA, port calls, crew changes via helicopter/Support Vessel, or vessel mobilisation/demobilisation to/from the OA. During these periods the Seismic Vessel and Support Vessels are deemed to be operating under the Commonwealth *Navigation Act 2012* (refer to **Table 4**) not managed within this EP.

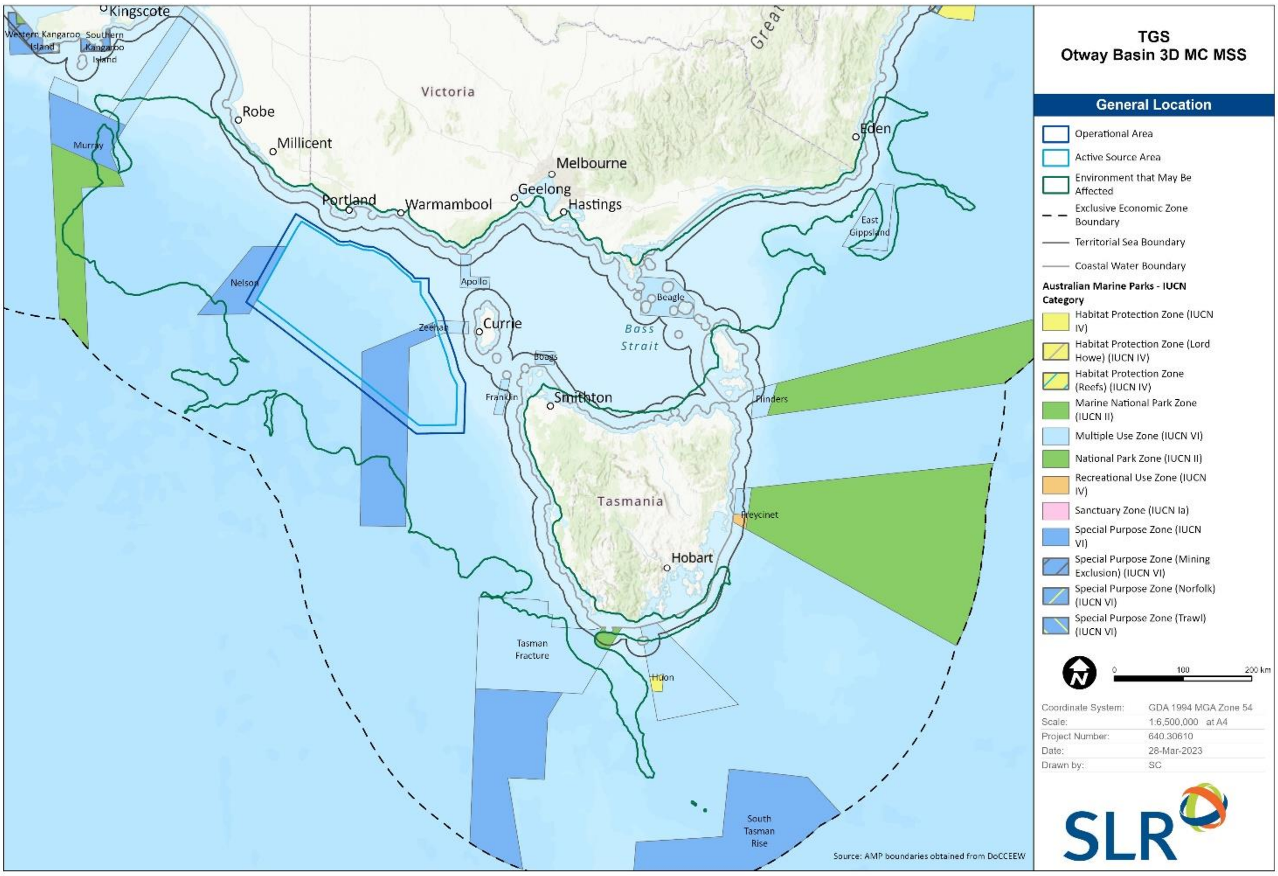

Figure 1 Location of the OA and EMBA

1.4 Environment Plan Summary

In accordance with the requirements of Regulation 11(4) within the Environment Regulations, an EP summary is provided in **Table 1**.

Table 1 EP Summary

EP summary parameter	Section
Location	**Section 3.2**
Description of the receiving environment	**Section 4**
Description of the activity	**Section 3**
Details of the environmental impacts and risks	**Section 7** (Planned); **Section 8** (Unplanned)
A summary of the control measures for the activity	Throughout **Section 7** (Planned); **Section 8** (Unplanned)
A summary of the arrangements for ongoing monitoring of the titleholder's environmental performance	Throughout **Section 7** (Planned); **Section 8** (Unplanned) and **Section 10.6.1**
A summary of the response arrangements in the OPEP	**Section 10.10**
Details of the consultation (already undertaken and proposed)	**Section 5**
Details of the titleholder's nominated liaison	**Section 1.5**

1.5 Titleholder and Nominated Liaison

TGS is the lead Titleholder for this activity. TGS is a leading energy data and intelligence company, known for its asset-light (TGS does not own towed acquisition vessels and equipment – all towed data acquisition activity is outsourced), multi-client business model and global data collection. TGS employs approximately 480 employees. TGS' primary business is to provide data and intelligence to companies and investors active in the energy sector.

In accordance with Regulation 15(1) of the Environment Regulations, details of the titleholder and nominated liaison person are detailed within **Table 2** and **Table 3**, below.

Table 2 Titleholder Details

Environment Regulation Requirements	Description
Titleholder	
Company name	TGS-NOPEC Geophysical Company Pty Ltd
Business address	Level 9, 220 St Georges Terrace, Perth WA 6000
Phone	+61 (0) 8 9480 0000
Fax	+61 (0) 8 9321 5312
Website	https://www.tgs.com/
CAN/ABN	48 077 150 424

Table 3 Nominated Liaison Person Details

Environment Regulation Requirements	Description
Contact Name	Tanya Johnstone
Company	TGS-NOPEC Geophysical Company Pty Ltd
Position	Director Australia, PNG and NZ
Business Address	Level 9, 220 St Georges Terrace, Perth WA 6000
Phone	+61 (0) 8 9480 0000
Email	Tanya.johnstone@tgs.com

As per Regulation 15(3) of the Environment Regulations, the nominated TGS Liaison Person (**Table 3**) or the TGS Project Manager (**Table 141**) will notify the National Offshore Petroleum Safety and Environmental Management Authority (**NOPSEMA**) both verbally and in writing, as soon as practicable, and prior to a change in the titleholder or the liaison person occurring. This protocol will also apply, should the contact details for either the titleholder or liaison person change.

1.6 TGS' Environment, Health and Safety Policies

As titleholder for the Otway Basin 3D MC MSS, TGS will implement this EP and undertake the petroleum activity in a manner consistent with the TGS Environment Policy (**Appendix A**).

TGS is committed to protecting the environment in which it lives and works, whilst also conducting operations in an environmentally sustainable and responsible manner. TGS strives to lead the industry in minimizing the impact of its operations on the environment and is dedicated to the continuous improvement of environmental programs and standards across all operations. The TGS corporate Environment Policy provides a public statement of the company's commitment to protecting the environment during offshore operations, including seismic surveys.

The TGS Health and Safety Policy aims to assist in providing a safe, healthy and sustainable workplace for employees, contractors, vendors and clients of TGS, while protecting the working environment. Accordingly, TGS outlines its commitment to the promotion and maintenance of the physical, psychological and social well-being of all employees.

TGS defines safe operating procedures in the Environment, Health and Safety Management System that has been designed to meet or exceed all appropriate legal requirements and, in the absence of any defined standards, to meet or exceed generally accepted best operating practices.

All levels of Management are responsible for the communication and implementation of TGS' Environment, Health and Safety Policies and Programs. Management is responsible for ensuring that employees are well equipped to meet health and safety requirements. These requirements are then reviewed on a regular basis to ensure ongoing sustainability and effectiveness.

2 Environmental Management Framework

2.1 Legislation Requirements

Petroleum and greenhouse gas storage activities, including MSSs, in 'offshore areas' – defined as those waters between the outer limit of coastal water (three nautical miles (**NM**)) and the outer limit of the Continental Shelf (at least 200 NM) – are required to be assessed and authorised under the OPGGS Act and associated Environment Regulations.

The following sections detail the requirements of the Environment Regulations, along with all applicable environmental management requirements that are relevant to the Otway Basin 3D MC MSS. **Section 2.1.1.1** provides a summary of the Environmental Regulations, in particular Regulation 13, and provides a road map to the relevant sections of this EP which describe how each requirement has been adhered to.

2.1.1 OPGGS Act

The OPGGS Act provides the regulatory framework for all offshore petroleum exploration, production and greenhouse gas activities in Australia's offshore areas. The OPGGS Act confers powers to NOPSEMA to regulate the health and safety, structural integrity and environmental management of petroleum exploration and development activities within Australia's offshore areas.

In addition to establishing the regulatory regime for environmental management authorisation, the OPGGS Act has other relevant powers, including:

- Requiring that an activity in an offshore area must be undertaken in a manner that does not interfere with navigation, fishing, conservation of the resources of the sea and seabed, any lawfully established activities of another person and the enjoyment of native title rights and interests;
- Requiring operations to be carried out in accordance with good oilfield practices;
- Requiring titleholders, in the event of an escape of petroleum, to eliminate or control the escape, clean up the escaped petroleum and remediate any resulting damage to the environment, and carry out environmental monitoring of the impact of the escape on the environment;
- Providing for NOPSEMA to give written directions to titleholders covering all aspects of petroleum exploration and production;
- Providing for remedial directions by NOPSEMA with regard to the restoration of the environment; and
- Requiring a titleholder to maintain in good condition and repair all structures and equipment that are used in connection with the operations authorised by the permit, lease, licence or authority.

The OPGGS Act is supported by regulations covering matters such as safety, diving, petroleum resource management and environmental management (see **Section 2.1.1.1**).

2.1.1.1 Environment Regulations

The Environment Regulations have been developed under the OPGGS Act and provide an objective-based regime for the management of environmental performance for Australian offshore petroleum exploration and production and greenhouse gas storage activities in areas of Commonwealth jurisdiction.

The objectives of the Environment Regulations are to ensure any activity is carried out:

- In a manner consistent with the principles of ESD (outlined further in **Section 2.1.2**);
- In a manner in which the environmental impacts and risks of the activity will be reduced to **ALARP**. To ensure the impacts and risks from the proposed activities are reduced to **ALARP**, a hierarchy of controls have been utilised which follows a tiered system which are defined within **Section 6.3**; and
- In a manner in which the impacts and risks will be of an **Acceptable Level**. The criteria used to determine whether the residual risk of an activity following the implementation of the control measures is at an **Acceptable Level** is provided within **Section 6.4**.

2.1.2 EPBC Act

The Environment Protection and Biodiversity Conservation Act 1999 (**EPBC Act**) is the Australian Government's central piece of environmental legislation which provides a legal framework to protect and manage nationally and internationally important flora, fauna, ecological communities and heritage places as matters of National Environmental Significance (**NES**). There are nine matters of NES to which the EPBC Act applies (outlined within Sections 12 to 24 of the EPBC Act), which are:

- World heritage properties;
- National heritage places;
- Wetlands of international importance (RAMSAR sites);
- Listed threatened species and ecological communities;
- Listed migratory species;
- Nuclear actions;
- Commonwealth marine areas;
- The Great Barrier Reef Marine Park; and
- Protection of water resources from coal seam gas development and large coal mining development.

The NES listed above are discussed in detail within **Section 4**, where relevant to the Otway Basin 3D MC MSS.

In relation to the listed threatened species and ecological communities, the EPBC Act has established a list of categories, including: extinct, extinct in the wild, critically endangered, endangered, vulnerable and conservation dependant. **Section 4.5** includes a description of the biological environment comprising the OA and EMBA, which includes some species that are listed as threatened. Where threatened species occur, this has been identified and further species-specific details provided.

The EP must describe matters protected under Part 3 of the EPBC Act and assess any impacts and risks to these. As outlined within **Section 2.1.1.1**, one objective of the Environment Regulations is to ensure that the activity is carried out in a manner consistent with the principles of ESD, the principles of which are set out in Section 3A of the EPBC Act as:

- Decision-making processes should effectively integrate both long-term and short-term economic, environmental, social and equitable considerations;
- If there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation;
- The principle of inter-generational equity – that the present generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations;
- The conservation of biological diversity and ecological integrity should be a fundamental consideration in decision-making; and
- Improved valuation, pricing and incentive mechanisms should be promoted.

The EPBC Act has been utilised throughout the development of this EP, particularly in relation to the existing environment (**Section 4**) and within the assessment of the impacts and risks from the proposed activity (**Section 7** and **Section 8**).

2.1.2.1 EPBC Act Policy Statement 2.1 – Interaction between Offshore Seismic Exploration and Whales

Under the EPBC Act, several whale species are listed as threatened and/or migratory species (see **Section 4.5.6**) and are subsequently protected under the EPBC Act as matters of NES. To manage the interaction between offshore seismic exploration and whales, the EPBC Act Policy Statement 2.1 – Interaction between Offshore Seismic Exploration and Whales (**Policy Statement 2.1**) was developed, with the aim being to:

- Provide practical standards to minimise the risk of acoustic injury to whales in the vicinity of MSS operations;
- Provide a framework that minimises the risk of biological consequences from acoustic disturbance from MSS sources to whales in biologically important habitat areas or during critical behaviours; and
- Provide guidance to both proponents of MSSs and operators conducting MSSs about their legal responsibilities under the EPBC Act.

The following sections provide an outline of the applicable provisions of Policy Statement 2.1.

2.1.2.1.1 Potential Impacts to be Considered

Section 4 of Policy Statement 2.1 discusses the potential impacts to be considered when planning a MSS, which has been utilised in the preparation of this EP. An important aspect to consider when assessing the likelihood of potential impacts on whales is determining whether the MSS will have a '*low likelihood'* or a '*moderate to high likelihood*' of encountering whales. Policy Statement 2.1 defines these terms as:

- Low likelihood – spatially and/or temporally outside aggregation areas, migratory pathways and areas considered to provide biologically important habitat; and
- Moderate to high likelihood – spatially and/or temporally proximate to aggregation areas, migratory pathways and/or areas considered to provide biologically important habitat.

In addition, identifying whether a proposed survey will occur within a biologically important habitat of a whale species is necessary because displacement from these areas may have a greater impact than elsewhere. An assessment into the likelihood of encountering whale species has been undertaken and included within **Section 4.5.6**, along with the identification of any areas which are biologically important habitats for those whale species.

2.1.2.1.2 Legislative Responsibilities

There are two obligations that need to be considered under the EPBC Act when developing a MSS: referrals and permits, defined as:

- Referrals – if an MSS has, or is likely to have, a significant impact on a matter of NES or the 'environment' (including threatened and migratory species) then that action should be referred to the Australian Government Environment Minister under the EPBC Act. The Minister may then determine the referral to be either a '*controlled action*' in which the action is subject to the assessment and approval processes under the EPBC Act, or not a controlled action where further approval is not required if the action is undertaken in accordance with the referral, or in a particular way specific in the decision notice.

  As part of the development of this EP, a number of control measures have been utilised when assessing the impact of the Otway Basin 3D MC MSS (contained throughout **Section 7** for planned activities, and **Section 8** for unplanned activities). Based on these control measures, overall, it is considered that the Otway Basin 3D MC MSS activities will not have a significant impact on a matter of NES or on the 'environment' in general.

- Permits – an action that will kill, injure, take or interfere with a whale or dolphin within the Australian Whale Sanctuary (see **Section 4.4.5**) is an offence under the EPBC Act, unless the proposed action has been referred to the Environment Minister and approved, or a permit has been granted. Generally, an MSS will not interfere with whales if it is undertaken in an area and at a time where the likelihood of encountering whales is low and appropriate measures are implemented.

  As outlined above, the likelihood of encountering whales during the Seismic Survey is discussed within **Section 4.5.6** and the control measures to be implemented are contained within **Sections 7** and **8**. Based on these sections, it is considered that the Seismic Survey will not kill, injure, take or interfere with a whale or dolphin within the Australian Whale Sanctuary.

2.1.2.1.3 Management Measures for Vessels Conducting Seismic Surveys in Australian Waters

Policy Statement 2.1 provides a discussion on the management measures for vessels and organisations looking to conduct MSSs within Australian waters. These measures are divided into two primary areas; Precautionary Zones and Management Procedures, as described in the following sections.

2.1.2.1.4 Precautionary Zones

Section 6.1 of Policy Statement 2.1 defines three zones (Observation, Low-power and Shut-down) which are to be used during MSSs, based on the likely sound levels surrounding the acoustic source. There are two levels of Precautionary Zones, dependant on the sound exposure level (**SEL**) each seismic emission makes which is to be demonstrated through sound modelling or empirical measurements.

If the received SEL will not likely exceed 160 decibels (**dB**) re 1 μPa^2s for 95% of seismic shots at 1 km range, the following Precautionary Zones are recommended under Policy Statement 2.1:

- Observation Zone: 3^+ km horizontal radius from the acoustic source;
- Low-power Zone: 1 km horizontal radius from the acoustic source; and
- Shut-down Zone: 500 m horizontal radius from the acoustic source.

For all other proposed MSSs, Policy Statement 2.1 recommends the following zones:

- Observation Zone: 3^+ km horizontal radius from the acoustic source;

- Low-power Zone: 2 km horizontal radius from the acoustic source; and
- Shut-down Zone: 500 m horizontal radius from the acoustic source.

A graphical representation of the three recommended zones is indicated within **Figure 2**.

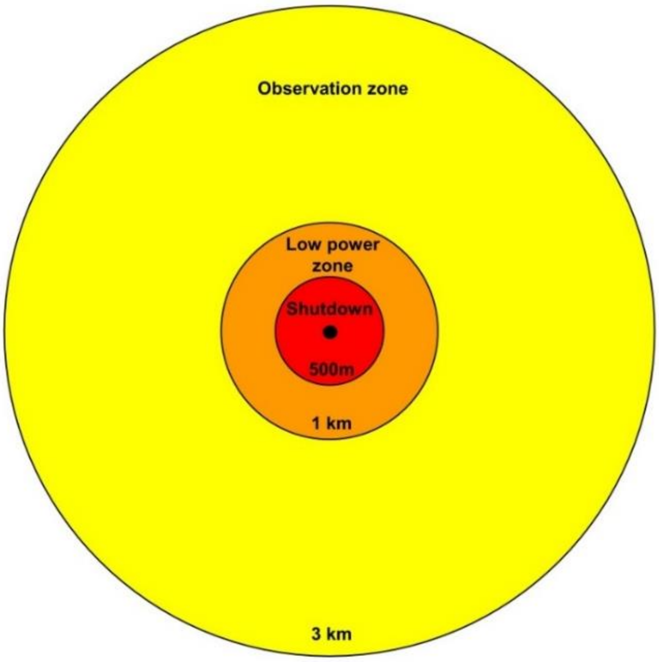

Diagram 1: Precaution zones surrounding the acoustic source for surveys that meet the criteria for a **1km low power zone**.

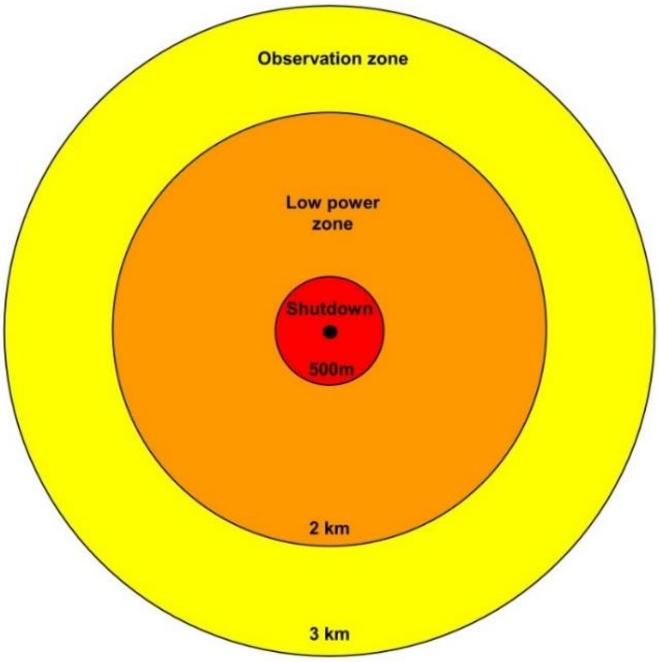

Diagram 2: Precaution zones surrounding the acoustic source for all other surveys (**2km low power zone**)

Source: EPBC Act Policy Statement 2.1 (DoEWHA, 2008)

Figure 2 Policy Statement 2.1 – Recommended Precautionary Zones

Each zone has differing requirements, as follows:

- Observation Zone – whales and their movements should be monitored to determine whether they are approaching or entering the 'Low-power Zone';
- Low-power Zone – when a whale is sighted within, or is about to enter this zone, the acoustic source should immediately be powered down to the lowest possible setting; and
- Shut-down Zone – when a whale is sighted within, or is about to enter this zone, the acoustic source must immediately be completely shut-down.

Underwater Acoustic Modelling (**UAM**) (**Appendix B**, **Section 7.2.1.2**) has been undertaken which has confirmed that the SEL exceeds the 160 dB re 1 µPa^{2}s, for 95% of seismic shots at 1 km range. Therefore, TGS will implement the more stringent Precautionary Zone requirements of the Policy Statement 2.1 (**Figure 2**). However, based on the UAM results and sensitivities in and surrounding the OA, additional management procedures will be implemented (**Section 7.2.3.3**).

2.1.2.1.5 Management Procedures

In addition to Precautionary Zones, Policy Statement 2.1 includes a number of management procedures which should be followed by all Seismic Survey Vessels (**Seismic Vessel**) conducting surveys in Australian waters irrespective of the location and time of year. Under Section 6.2 of Policy Statement 2.1, these management procedures are split into 'Standard Management Procedures' and 'Additional Management Procedures'. Standard Management Procedures include:

- Pre-survey planning – ideally, no MSS will be planned to be conducted when whales are likely to be breeding, calving, resting or feeding. If an MSS is proposed to occur during such periods, careful consideration of the survey and associated control measures will need to be undertaken;
- Trained crew – sufficiently trained crew, including people with proven experience in whale observation, distance estimation and reporting, are required to undertake relevant requirements during survey operations;
- During survey – all Seismic Vessels operating in Australian waters are required to follow basic procedures during surveys irrespective of location and time of the year, including:
  - Pre-start-up visual observations;
  - Soft-start;
  - Start-up delay;
  - Operations;
  - Power-down and stop work; and
- Compliance and sighting reports – a record of procedures employed during operations is required, including information on any whales (or other species) sighted during the MSS. This information may be useful for future operations.

When an MSS is proposed to operate in areas where the likelihood of encountering whales is moderate to high then Additional Management Procedures are required to ensure that impacts and interference are avoided and/or minimised. Suggested Additional Management Procedures under Section 6.2 of Policy Statement 2.1 include:

- Marine Fauna Observer (**MFO**) – MFOs should be trained and experienced in whale identification and behaviour, distance estimation, be capable of making accurate identifications and observations of whales in Australian waters, and can assist other observers on the Seismic Vessel;
- Night-time/poor visibility – appropriate management measures to detect (or predict) whale presence should be included to reduce the likelihood of encounters, including limiting initiation of Soft-start Procedures, or the use of a daylight spotter vessel or aircraft and pre-survey research;
- Spotter vessel(s) and aircraft – a spotter vessel/aircraft could be used to assist in detecting the presence of whales, including during night-time/poor visibility operations;
- Increase Precaution Zones and Buffer Zones – in some locations and circumstances an increased distance for the instigation of Power-down Procedures (discussed above) is advisable;
- Passive Acoustic Monitoring (**PAM**) – deployment of PAM to detect whales in real-time may provide an additional method of detecting whales during surveys, particularly during night-time/poor visibility operations; and
- Adaptive Management – Adaptive Management Procedures should be considered to manage the potential increased likelihood of encountering whales; for example, ceasing night-time operations if there are three consecutive days on which operators experience three or more whale-instigated shut-down/power down situations.

An assessment of the likelihood of encountering whales has been undertaken within **Section 4.5.6**, based on the 'presence ranking' (as assigned by the Protected Matters Database for both the OA and EMBA) which has concluded that whales are known to occur within the OA and EMBA. Therefore, Additional Management Procedures will be required. The additional procedures that will be included are discussed within **Section 7.2**.

2.1.2.2 Environment Protection and Biodiversity Conservation Regulations 2000

The Environment Protection and Biodiversity Conservation Regulations 2000 (**EPBC Regulations**) implement the provisions of the EPBC Act and provide additional measures to control a range of activities, including the use of vehicles and vessels, littering, commercial activities, research, and commercial and recreational fishing. In particular, Part 8 of these regulations relates to appropriate actions when cetaceans are in the vicinity of vessels. The relevant provisions of Part 8 have been considered when determining the impacts and risks associated with the Otway Basin 3D MC MSS (**Section 7**).

2.1.2.3 EPBC Act Management Plans

When a native species or ecological community is listed as threatened under the EPBC Act, conservation advice is developed to assist with its recovery. Conservation advice provides guidance on the immediate recovery and threat abatement activities that can be undertaken to ensure the conservation of a newly listed species or ecological community.

The Minister for the Environment may make or adopt and implement recovery plans for threatened fauna, threatened flora (other than conservation dependent species) and Threatened Ecological Communities (**TEC**) listed under the EPBC Act. Recovery plans define the research and management actions necessary to stop the decline of, and support the recovery of, listed threatened species or TECs. The aim of a recovery plan is to maximise the long-term survival in the wild of a threatened species or ecological community.

The Otway Basin 3D MC MSS will be conducted in a manner that is consistent with the conservation advice and recovery plans for species with the potential to be present in the OA. **Section 4.5** describes the species that are listed as threatened and/or migratory under the EPBC Act, which have been identified to occur within the Environment that May Be Affected (**EMBA**) (see **Section 4.1, Figure 7**) and identifies the relevant conservation advices and recovery plans. In addition, any relevant measures contained within the conservation advice and recovery plans have been considered as part of the assessment of impacts and risks that may occur as a result of the Otway Basin 3D MC MSS (**Section 7**).

2.1.3 Other Relevant Legislation

Regulation 13(4) of the Environment Regulations requires a description of the relevant legislative requirements that apply to the activity and are relevant to the environment management of the activity. Several legislative instruments exist which are relevant to the Otway Basin 3D MC MSS. The key pieces of Commonwealth legislation (other than the OPGGS Act and EPBC Act discussed above) that are relevant to the environmental management of the Seismic Survey are outlined within **Table 4**, along with a discussion on how each of these requirements will be achieved.

The Otway Basin 3D MC MSS is located within Commonwealth waters, and therefore falls under the Commonwealth legislation; however, in the unlikely event of a hydrocarbon spill occurring and entering State waters, State legislation would be triggered. As the risk of this unplanned event occurring is considered to be remote a full assessment of all of the State legislation has not been conducted; however, **Section 10.10** provides an overview of TGS' arrangements for a response to the unlikely event of a hydrocarbon spill, including how the relevant statutory plans will be implemented, should the spill enter State waters.

Table 4 Summary of Key Commonwealth Legislation Relevant to the Otway Basin 3D MC MSS

Legislation	Applicability
Australian Heritage Council Act 2003	The Australian Heritage Council Act established the Australian Heritage Council as an independent expert advisory body on heritage matters. The main responsibilities of the Australian Heritage Council relate to assessing places for the National Heritage List and the Commonwealth Heritage List. An assessment of the heritage values associated with the OA is outlined within **Section 4.6.2**.
Australian Maritime Safety Authority Act 1990	This Act established the Australian Maritime Safety Authority (**AMSA**), which has the responsibility of protecting the marine environment from pollution from ships, and other environment damage resulting from shipping activities. This Act facilitates international cooperation and mutual assistance in preparing and responding to major oil spill incidents and encourages countries to develop and maintain an adequate capability to deal with oil pollution emergencies. Responsibilities of AMSA include being the lead agency when responding to hydrocarbon spills within the marine environment under the National Plan for Maritime Environmental Emergencies (known as the **National Plan**). Given the Otway Basin 3D MC MSS will take place in the marine environment, there is always a remote risk of pollution or other incidents as a result of survey operations. The potential risks from an unplanned activity occurring in association with the Otway Basin 3D MC MSS is assessed within **Section 8**. This assessment also provides the measures that will be implemented throughout the survey to reduce these risks to **ALARP** and an **Acceptable Level**.
Biosecurity Act 2015 Biosecurity Regulations 2016	This Act details how biosecurity threats to plant, animal and human health in Australia and its external territories are managed. Section 4 of this Act describes the objectives as: *(a) To provide for managing the following:* *(i) Biosecurity risks;* *(ii) The risk of contagion of a listed human disease or any other infectious human disease;*

Legislation	Applicability
Biosecurity Amendment (Biofouling Management) Regulations 2021	*(iii) The risk of human diseases or any other infectious human diseases entering Australian territory or a part of Australian territory, or emerging, establishing themselves or spreading in Australian territory or a part of Australian territory;* *(iv) Risks related to ballast water;* *(v) Biosecurity emergencies and human biosecurity emergencies;* *(b) To give effect to Australia's international rights and obligations, including under the International Health Regulations, the SPS Agreement, the Ballast Water Convention, the United Nations Convention on the Law of the Sea and the Biodiversity Convention.* The Biosecurity Amendment (Biofouling Management) Regulations 2021 entered into force on 15 June 2022 and requires all vessels to provide information on biofouling management practices prior to arriving in Australia. This is achieved through the Pre-Arrival Report (**PAR**) which now also includes mandatory questions relating to biofouling management practices. Vessel operators can demonstrate proactive management of biofouling by implementing one of three accepted proactive biofouling management options or answer further pre-arrival questions to inform assessments of the biosecurity risk associated with biofouling on vessels. The administering authority for biosecurity legislation is the Department of Agriculture, Fisheries and Forestry (**DAFF**). There are a number of relevant legislative documents that have been prepared to deal with the issue of biosecurity (discussed in **Section 8.1**); all of which have been considered as part of the preparation of this EP, specifically in relation to the assessment of environmental risks associated with invasive marine species (**IMS**) (**Section 8**).
Environment Protection (Sea Dumping) Act 1981	The Environment Protection (Sea Dumping) Act 1981 is administered by the Australian Government Department of the Environment and Energy (**DoEE**) and is aimed at protecting the waters surrounding Australia's coastlines from wastes and pollution dumped at sea. In addition, this Act fulfils Australia's international obligations under the Convention on the Prevention of Marine Pollution by Dumping of Wastes and Other Matter 1972, and 1996 Protocol (**the London Protocol**). The aim of this Act is to minimise pollution threats by: • Prohibiting ocean disposal of waste considered too harmful to be released into the marine environment; and • Regulating permitted waste disposal to ensure environmental impacts are minimised. Since the Otway Basin 3D MC MSS will involve the use of survey vessels within Australian waters, the management and operation of the vessels will be subject to this Act. Although no waste or other matter (other than routine permissible vessel discharges, see **Section 7.3**) is proposed to be discharged within Australian waters as part of this EP, there is always a remote chance of an accident occurring where such waste or equipment could be lost overboard. **Section 8.5** outlines the potential risks and associated impacts if an accidental discharge occurs, along with the measures that TGS will implement to reduce the risk to **ALARP** and within **Acceptable Levels**.
Navigation Act 2012	This act regulates international ship and seafarer safety, shipping aspects of protecting the marine environment and the actions of seafarers in Australian waters. The Act gives effect to the relevant aspects of the International Convention for the Prevention of Pollution from Ships 1973, as modified by the Protocol of 1978 (**MARPOL**), the United Nations Convention on the Law of the Sea 1982 (**UNCLOS**) and the International Regulations for Preventing Collisions at Sea 1972 (**COLREGS**), among other international treaties, details of which are outlined below: • MARPOL is the main international convention covering prevention of pollution of the marine environment by ships from operational or accidental causes. The Annexes of MARPOL that Australia is a party to are given effect to by current legislation; • UNCLOS lays down a comprehensive regime of law and order in the world's oceans and seas establishing rules governing all uses of the oceans and their resources; and

Legislation	Applicability
	• COLREGS set out the navigational rules to be followed by ships and vessels at sea to prevent collisions. These Regulations will be important in maintaining safe operating procedures to ensure collisions don't occur during the Otway Basin 3D MC MSS. In addition to the above international treaties, several Marine Orders are enacted under the Navigation Act 2012 which relate to offshore petroleum activities, including: • Marine Order Part 21: Safety and emergency arrangements; • Marine Order Part 27: Safety of navigation and radio equipment; • Marine Order Part 28: Operations standards and procedures; • Marine Order Part 30: Prevention of collisions; and • Marine Order Part 58: Safe management of vessels. The administering authority of this Act is **AMSA**. Since the Seismic Vessel proposed to be used for the Otway Basin 3D MC MSS will be operating within Australian waters, the management and operation of the vessel will be subject to this Act and associated Marine Orders. The relevant aspects of this Act and subsequent Marine Orders, along with the international treaties that provide control measures to avoid potential unplanned risks associated with this activity are discussed within **Section 8**.
Ozone Protection & Synthetic Greenhouse Gas Management Act 1989	This Act regulates the manufacture, importation and use of ozone depleting substances (**ODS**) which are typically used in fire-fighting equipment and refrigerants. The use of these substances is discussed within **Section 7.4** which stipulates that no ODS will be deliberately released.
Protection of the Sea (Civil Liability of Bunker Oil Pollution Damage) Act 2008	This Act establishes a liability and compensation regime to apply in cases of pollution damage following the escape of bunker oil from a ship that is not an oil tanker. This Act prescribes that ship owners are strictly liable for pollution damage resulting from the escape or discharge of bunker oil from their ships; resulting in the obligation on ships over 1,000 gross tonnages to carry insurance certificates when leaving/entering Australian ports. The Seismic Vessel undertaking the Otway Basin 3D MC MSS will hold the necessary insurance certificates.
Protection of the Sea (Harmful Anti-fouling Systems) Act 2006	This Act was developed as part of Australia's commitment to MARPOL and the International Convention on the Control of Harmful Anti-fouling Systems on Ships and regulates the use of anti-fouling compounds and systems in Australian waters. It is an offence to engage in negligent conduct that results in a harmful anti-fouling compound being applied to a ship. Australian ships must hold anti-fouling certificates, provided they meet certain criteria. The vessels to be used for the Otway Basin 3D MC MSS will have anti-fouling management regimes in place that are consistent with this Act.
Protection of the Sea (Prevention of Pollution from Ships) Act 1983 Maritime Legislation Amendment (Prevention of Air Pollution from Ships) Act 2007	MARPOL includes regulations aimed at preventing both accidental pollution and pollution from routine vessel operations. Australia implements MARPOL through the Protection of the Sea (Prevention of Pollution from Ships) Act 1983 (**PSPPS Act**) and the Navigation Act 2012 (discussed above). The PSPPS Act (and the Navigation Act), along with the following Commonwealth legislation gives effect to MARPOL: • Marine Order 91: Marine pollution prevention – oil; • Marine Order 93: Marine pollution prevention – noxious liquid substances; • Marine Order 94: Marine pollution prevention – packaged harmful substances; • Marine Order 95: Marine pollution prevention – garbage; • Marine Order 96: Marine pollution prevention – sewage; • Marine Order 97: Marine pollution prevention – air pollution; and

Legislation	Applicability
	• Marine Order 98: Marine pollution prevention – anti-fouling systems. The PSPPS Act, and the associated legislation listed above have been considered as part of the impact and risk assessment detailed within **Section 7**.
Underwater Cultural Heritage Act 2018	This Act came into effect on 1 July 2019 replacing the Historic Shipwrecks Act 1976 and continues to protect Australia's shipwrecks, sunken aircraft and other types of underwater heritage (including human remains) that have lain in territorial waters for 75 years or more. In addition to the general protection provided to underwater heritage sites, this Act also provides for areas containing protected underwater heritage to be declared a protected zone. These may be established for a number of reasons including conservation, management or public safety. Most protected zones cover an area of around 200 hectares, although there is flexibility to declare a larger zone if necessary. Underwater protected zones are described in **Section 4.6.2.**

Although the Otway Basin 3D MC MSS will be conducted within Commonwealth waters (between 3 and 200 NM from the territorial baseline), emitted sound levels may spread into State waters, and in the very unlikely event of a hydrocarbon spill occurring, spilt hydrocarbons may enter State waters, triggering State legislation. Therefore, an assessment of key State legislation is outlined within **Table 5.**

Table 5 Key State Legislation Relevant to the Otway Basin 3D MC MSS

Legislation	Applicability
Victoria	
Marine and Coastal Act 2018	Provides a simple, integrated and coordinated approach to planning and managing the marine and coastal environment. This is done by enabling the protection of the coastline and the ability to address the long-term challenges of climate change, population growth and ageing coastal structures; along with ensuring that partners work together to achieve the best outcomes for VIC's marine and coastal environment. This Act is complemented by VIC's Marine and Coastal Reforms Final Transition Plan which identifies a programme of policy reforms and on-the-ground actions to transition to the new system over the coming years.
Environment Protection Act 2017 and the Environment Protection Act 1970	The Environment Protection Act 1970, and the updated Environment Protection Act 2017, is the key VIC legislation that applies to noise emissions and the air, water and land in VIC, the territorial sea along the VIC coast and to discharges of waste to the Murray River. This Act created the Environment Protection Authority VIC which has a legislated objective to protect human health and the environment by reducing the harmful effects of pollution and waste. A number of regulations under these Acts regulate the management arrangements for ballast water. The ship masters of the survey vessels will abide by all requirements in relation to ballast water management, which is discussed within **Section 8.1** relating to the spread of invasive marine species.
Heritage Act 2017	The Heritage Act is administered by Heritage VIC and is the key cultural heritage legislation. It identifies and protects heritage places and objects that are of significance to VIC, including shipwrecks and artefacts. All shipwrecks and shipwreck relics in VIC waters that are at least 75 years old are protected by the establishment of protected zones and the prohibition of certain activities in relation to historic shipwrecks. **Section 4.6.2** provides an assessment of the maritime heritage.

Legislation	Applicability
Emergency Management Act 2013	The Emergency Management Act 2013 established Emergency Management VIC and operates concurrently with the Emergency Management Act 1986 which will ultimately be repealed. This Act established the State Crisis and Resilience Council which is responsible for providing emergency management policy and strategy advice to the VIC Government; along with the Inspector-General for Emergency Management whose functions include developing and maintaining a monitoring and assurance framework along with the State Emergency Response Plan and the State Emergency Recovery Plan.
Marine Safety Act 2010	The Marine Safety Act and its associated Marine Safety Regulations provide for safe marine operations in VIC. The Act and Regulations set out a range of requirements including safety duties for persons and parties responsible for marine safety. This Act reflects the requirements of various international conventions which will be met during the Otway Basin 3D MC MSS.
Flora and Fauna Guarantee Act 1988	The Flora and Fauna Guarantee Act is the key piece of legislation in VIC in terms of the conservation of threatened species and communities and for the management of potentially threatening processes. Its aim is to conserve all of VIC's native plants and animals by establishing a range of mechanisms, including (among others) listing threatened species, communities and threats to native species.
Pollution of Waters by Oil and Noxious Substances Act 1986	The purpose of this Act is to protect the sea and other waters from pollution by oil and noxious substances and implements the International Convention for the Prevention of Pollution from Ships 1973. The potential impacts from routine permissible waste discharges is assessed within **Section 7.3**.
National Parks Act 1975	The National Parks Act, along with the National Parks Regulations 2013 provide for the preservation and protection of the natural and cultural heritage values of the parks, including marine national parks and coastal parks. An assessment of the marine protected and sensitive areas in the coastal environment is described within **Section 4.4**.
South Australia	
Marine Parks Act 2007	The Marine Parks Act has the aim of protecting and conserving marine biodiversity and habitats by providing for the establishment and management of marine parks in South Australian waters. The Regulations under this Act prohibit certain activities within the certain marine park zones, with exemptions for some activities, such as for persons acting in the course of an emergency. An assessment of the marine protected and sensitive areas in the coastal environment is described within **Section 4.4**.
Emergency Management Act 2004	The Emergency Management Act establishes a framework for the management of emergencies in South Australia and provides for the establishment of among others, the State Emergency Management Plan which comprises strategies for the prevention of emergencies in the State. This Act has been taken into account in the development of this EP.
Protection of Marine Waters (Prevention of Pollution by Ships) Act 1987	This Act provides for the protection of the sea and State waters from pollution by ships from oil and noxious substances. This Act provides penalties for discharges of oil or of an oily mixture if it occurs within State waters, unless it is exempt for a variety of reasons outlined n Part 2 of the Act. The survey vessels to be used during the Otway Basin 3D MC MSS will meet the requirements of this Act when transiting into State waters.
Coast Protection Act 1972	The Coast Protection Act provides for the conservation and protection of the beaches and coast of South Australia. A Coast Protection Board was formed in 2017 with the proclamation of the Act with, among other things, the protection of the coast from pollution and misuse. Any potential impacts from the Otway Basin 3D MC MSS would be in relation to the unlikely event of a hydrocarbon spill which is assessed within **Section 8.3**.

Legislation	Applicability
National Parks and Wildlife Act 1972	The National Parks and Wildlife Act is the principal legislation in South Australia in respect to the establishment and management of protected areas. Potential impacts on the area inshore of the OA would be in relation to the unlikely event of a hydrocarbon spill which is assessed within **Section 8.3**.
Tasmania	
Pollution of Waters by Oil and Noxious Substances Act 1987	This Act deals specifically with discharges of oil and other pollutants from ships and gives effect in TAS to the International Convention for the Prevention of Pollution from Ships 1973. The potential impacts from routine permissible waste discharges is assessed within **Section 7.3**
Environmental Management and Pollution Control Act 1994	This Act is the primary environment protection and pollution control legislation in TAS with the fundamental basis being the prevention, reduction, and remediation of environmental harm. The potential impacts from routine permissible waste discharges is assessed within **Section 7.3**.
Emergency Management Act 2006	The Emergency Management Act outlines the prevention, preparedness, and response and recovery procedures in order to protect life, property and the environment in a declared State emergency. The potential risks of an emergency occurring during the Otway Basin 3D MC MSS is discussed within **Section 8.3**.

2.2 Relevant Guidelines, Standards and Codes

Australian Ballast Water Management Requirements (Version 8)

These requirements include legislative obligations under the Biosecurity Act 2015, and the International Convention for the Control and Management of Ships' Ballast Water and Sediments regarding the management of ballast water and ballast tank sediment when operating within Australian waters. These requirements, along with the Biosecurity Act (discussed in **Table 4**), have been provided for in relation to the assessment of environmental risks associated with invasive marine species (**Section 8**).

Australian Biofouling Management Requirements (Version 1)

These requirements outline the obligations placed on vessel operators for the management of biofouling when operating vessels under biosecurity control within Australian territorial seas. Under these requirements, all vessel operators intending to enter Australian territorial waters must provide information relating to biofouling management through the mandatory PAR. Information provided by vessel operators in the PAR process may be inspected to verify its accuracy and/or an inspections of vessels' submerged hull and niche areas may be conducted. These requirements have been provided for in relation to the assessment of environmental risks associated with IMS (**Section 8.1**).

Code of Environmental Practice 2008 – Australian Petroleum Production and Exploration Association (APPEA)

This Code provides guidance on ensuring that exploration and production operations are conducted using effective management in order to be sustainable within the Australian environment. This includes the need to avoid or minimise and manage impacts to the environment, focusing on four basic recommendations:

1. Assess the risk to, and impacts on, the environment as an integral part of the planning process;
2. Reduce the impact of operations on the environment, public health and safety to **ALARP** and to an **Acceptable Level** by using the best available technology and management practises;
3. Consult with relevant persons regarding industry activities; and

4. Develop and maintain a corporate culture of environmental awareness and commitment that supports the necessary management practices and technology, and their continuous improvement.

These recommendations, which effectively mirror the requirements within the Environment Regulations, have been considered when assessing the potential impacts and risks from the Seismic Survey during the development of this EP (**Sections 7** and **8**).

Convention on the Conservation of Migratory Species of Wild Animals

The Convention on the Conservation of Migratory Species of Wild Animals (known as the **Bonn Convention**) provides a global platform for the conservation and sustainable use of migratory animals and their habitats. The Bonn Convention was entered into force in 1983, with Australia being a party since September 1991. The Bonn Convention includes obligations for parties to it, including:

- Acknowledging the importance of conserving migratory species;
- Promote, cooperate and support research relating to migratory species;
- For endangered species, endeavour to take measures to conserve the species and its habitat, prevent the adverse effects of activities that impede or prevent migration, prevent or minimise factors that endanger the species where possible, and make the taking of the species prohibited (subject to limited exceptions); and
- For species that are defined as having an 'unfavourable conservation status', endeavour to conclude agreements which would benefit and prioritise those species (Parliament of Australia, 2018).

The species of relevance from the Bonn Convention and the associated obligations are addressed under the EPBC Act. An assessment of those migratory species relevant to the Otway Basin 3D MC MSS are outlined throughout **Section 4.5**.

Convention on Oil Pollution Preparedness, Response and Cooperation 1990

Parties to the International Convention on Oil Pollution Preparedness, Response and Co-operation (**OPRC**) are required to establish measures for dealing with pollution incidents, either nationally or in co-operation with other countries. The OPRC comprises national arrangements for responding to oil pollution incidents from ships, offshore oil facilities, seaports, and oil handling facilities. The convention recognises that in the event of a pollution incident, prompt and effective action is essential.

The OPRC requires ships to carry a Shipboard Oil Pollution Emergency Plan (**SOPEP**). In addition, operators of offshore units under the jurisdiction of the parties to the OPRC are required to have an Oil Pollution Emergency Plan (**OPEP**), or similar arrangements which must be co-ordinated with national systems for responding promptly and effectively to oil pollution incidents. The vessel contracted to undertake the Otway Basin 3D MC MSS will have a SOPEP in place; and in the unlikely event of a spill occurs from a vessel collision/sinking, TGS will implement the response strategy in accordance with the SOPEP (see **Sections 8.3** and **8.4**).

Convention on Wetlands of International Importance especially as Waterfowl Habitat 1971

Commonly known as the **Ramsar Convention** (on account of it being signed in the Iranian town of Ramsar), the Ramsar Convention's board aims are to halt the worldwide loss of wetlands and to conserve, through wise use and management, those that remain. This has broadened over time to cover all aspects of wetland conservation and wise use (broadly defined as maintaining the ecological character of a wetland), recognising that wetland ecosystems are important for both biodiversity conservation and the well-being of human communities (DoEE, 2018a).

All wetlands listed under the Ramsar Convention as recognised as matters of NES under the EPBC Act, requiring approvals for actions that will have or are likely to have significant impacts on the ecological character of a Ramsar listed wetland. An assessment of the wetlands in or near the EMBA is outlined within **Section 4.4.6**, with any potential impacts and risks from the Otway Basin 3D MC MSS being assessed throughout **Sections 7** and **8**.

International Association of Geophysical Contractors (IAGC) Environment Manual for Worldwide Geophysical Operations 2013

Provides the industry with information for conducting geophysical field operations in an environmentally sensitive manner.

IAGC Mitigations Measures for Cetaceans during Geophysical Operations 2015

Provides recommended mitigation measures for cetaceans during geophysical operations. IAGC recommends implementing the suggested controls (mentioned in the document) in the absence of regulations or guidelines.

International Association of Oil and Gas Producers (IOGP) Recommended Monitoring and Mitigation Measures for Cetaceans during Marine Seismic Survey Geophysical Operations 2017

Provides recommendations on applying mitigation measures for cetaceans during geophysical operations. The measures outlined in this report are recommended for use during all marine seismic surveys that use compressed air source arrays, and are only intended for cetaceans (whales, dolphins, and porpoises).

International Convention for the Regulation of Whaling

The International Convention for the Regulation of Whaling is the International Whaling Commission's founding document and was signed in 1946. Obligations under this convention include the complete protection of certain species, and the establishment of whale sanctuaries. All Commonwealth waters of Australia are assigned as the Australian Whale Sanctuary (**Section 4.4.5**).

International Maritime Organisation (IMO) Guidelines for the Control and Management of Ships' Biofouling to Minimise the Transfer of Invasive Aquatic Species (Biofouling Guidelines) 2011

Provides a globally consistent approach to the management of biofouling. The approach was adopted by the Marine Environment Protection Committee in July 2011.

International Standards of Training, Certification and Watch-keeping for Seafarers, 1978

The International Convention of Standards of Training, Certification and Watch-keeping for Seafarers (**STCW Convention**), 1978, sets the mandatory minimum standards of training, certification and watch-keeping for masters, officers and watch personnel on seagoing merchant ships registered under the flag of a country party to the convention. As the survey vessels proposed to be used for the Otway Basin 3D MC MSS will be operating within Australian waters, the masters, officers, and watch personnel of the vessels will be subject to this convention. Aspects of the survey vessel operations that relate to this convention are discussed within **Sections 7** and **8**.

National Biofouling Management Guidance for the Petroleum Production and Exploration Industry 2009

This guidance document aims to provide assistance in regard to minimising the amount of biofouling accumulating on vessels, infrastructure and submersible equipment, and thereby minimising the risk of spreading marine pests around the Australian coastline. This guidance document has been utilised in determining the **Acceptable Levels** of risks associated with the Seismic Survey, and the environmental performance outcomes (**EPO**) and EPSs (**Section 8**).

National Light Pollution Guidelines for Wildlife Including Marine Turtles, Seabirds, and Migratory Shorebirds 2020

In January 2020, the Department of Agriculture, Water and the Environment released the '*Draft National Light Pollution Guidelines for Wildlife Including Marine Turtles, Seabirds and Migratory Shorebirds*'. The aim of this Guideline is to manage artificial light so that wildlife is not disrupted, nor displaced from important habitat and is able to undertake critical behaviours such as foraging, reproduction and dispersal.

It is noted that the Guidelines are in draft form and are yet to be finalised for implementation.

United Nations Convention on Biological Diversity

Australia is a party to the United Nations Convention on Biological Diversity. This Convention has three main objectives: the conservation of biological diversity, the sustainable use of components of biological diversity, and the fair and equitable sharing of the benefits arising out of the utilisation of genetic resources (CBD, 2018).

This Convention covers a range of topics and requirements which are subsequently implemented in Australia via different means, including Australia's Biodiversity Conservation Strategy 2010-2030 which is the guiding framework for the conservation of Australia's national biodiversity to 2030. An assessment of the biological environment is outlined within **Section 4.5**, with any potential impacts and risks from the Seismic Survey being assessed throughout **Sections 7** and **8**.

United Nations Declaration on the Rights of Indigenous Peoples

The United Nations Declaration on the Rights of Indigenous Peoples was adopted by the General Assembly on 13 September 2007, with the Australian Government announcing its support on 3 April 2009. This Declaration establishes a universal framework of minimum standards for the survival, dignity, and well-being of the indigenous peoples of the world and elaborates on the human rights standards and fundamental freedoms as they apply to the specific situation of indigenous peoples (United Nations, 2018). **Section 4.6.1** provides an assessment of the aboriginal heritage associated with the OA to provide an understanding of potential impacts on that heritage from the Otway Basin 3D MC MSS.

2.3 Relevant NOPSEMA Guidance Documents

Various NOPSEMA guidance documents have been utilised through the development of this EP to ensure that it meets all the requirements of the Environment Regulations and the expectations of NOPSEMA. These documents include:

- Guidance Notes:
  - ALARP (N-04300-GN0166 A138249, August 2022);
  - Environment plan content requirements (N-04750-GN1344 A339814, December 2022);
  - Responding to Public Comment on Environment Plans (N-04750-GN1847 A662607, July 2022);
  - Petroleum Activities and Australian Marine Parks (N-04750-GN 1785 A620236, June 2023);
  - Oil Pollution Risk Management (N-04750-GN1488 A382148, July 2021);
  - Notification and Reporting of Environmental Incidents (N-03000-GN0926 A710941, June 2020);
  - Control measures and performance standards (N-04300-GN0271 A336398, June 2020);
- Guidelines:
  - Consultation in the Course of Preparing an Environment Plan (N-04750-GL2086 A900179, May 2023);
  - Making Submissions to NOPSEMA (N-04000-GL0225, A15266, July 2022);
  - Environment Plan Decision Making (N-04750-GL1721, A524696, December 2022);
- Policy:
  - Environment Plan Assessment (N-04750-PL1347, A662608. December 2022);
  - Financial Assurance for Petroleum Titles (N-04730-PL1780, May 2020)
- Forms:

3 Project Description

3.1 Survey Overview

TGS is proposing to carry out the Otway Basin 3D MC MSS to collect high-quality geophysical data regarding rock formations and structures beneath the seabed in the Otway Basin.

During the survey, a Seismic Vessel will tow an acoustic source array and a series of streamers within the OA, as defined in **Section 3.2.1**. MSSs use data acquired through the use of a controlled acoustic source mechanically generating a sound wave that is transmitted downwards towards and into the seabed. The sound wave source uses compressed air to create a pulse of acoustic energy. The pulse of acoustic energy travels through the water column and into the seabed where energy is reflected at different speeds and intensities depending on the sediment type and/or density of the various sedimentary layers. The reflected acoustic signals are detected by an array of sensitive hydrophones located in each streamer, which are towed behind the Seismic Vessel (**Figure 3**). These sound signals are then analysed and processed into visual images of the subsurface structure of the seabed using powerful on-board computers and software.

The Seismic Vessel will be assisted by support vessels.

Figure 3 Schematic of an MSS

A summary of the general survey programme is provided in **Table 6**. Specific details of the Otway Basin 3D MC MSS are further described throughout **Sections 3.2** - **3.5**.

Table 6 Summary of General Parameters of the Otway Basin 3D MC MSS

General Programme Parameter	Description
Location	Otway Basin
Operational Area	55,000 km^2
Acquisition Area	45,000 km^2
Water Depths in Acquisition Area	115 m to 5,000 m*
Timing	Q4 2023/Q1 2024 commencement
Planned Survey Duration	Maximum of 200 days per year with a total of 400 days.

*A single 2D tie line will enter shallower waters of approximately 115 m, however, all 3D sail lines are within water depths greater than 500 m.

3.2 Survey Location

The OA for the Otway Basin 3D MC MSS is in Commonwealth waters in the Otway Basin, offshore from south-eastern Australia. Survey activities associated with the Otway Basin 3D MC MSS will be undertaken within the OA. The Acquisition Area (**AA**), as defined within **Section 3.2.1** and **Section 3.2.2** and depicted in Figure 4 is inside of the OA and is where the seismic data will be acquired. A third area, the EMBA has also been defined regarding an unplanned oil spill and is discussed further in **Section 4.1**. It is important to note that the AA is also referred to, and shown, as the Active Source Area on some of the figures within this EP.

3.2.1 Operational Area

The OA is the broadest area and represents the area where all activities managed under the EP will take place. It includes both the AA and a surrounding buffer that could be used for operational purposes (see **Figure 4**). The coordinates of the OA are provided in **Table 7**. Water depths within the OA range from approximately 97 m to 5,000 m.

The OA is located approximately 38 km from the mainland at the closest point. Other key coastal locations of relevance to the OA include:

- Portland, VIC: 45 km north of the OA;
- Warrnambool, VIC: 61 km north-northeast of the OA;
- Arthur River, TAS: 85 km east of the OA;
- King Island, TAS: 39 km east of the OA; and
- Port MacDonnell, SA: 39 km north of the OA.

Activities that will take place within the OA include streamer deployment and retrieval, seismic acquisition, maintenance, recovery, bubble tests, refuelling, vessel manoeuvring and soft-starts (see **Section 3.5.3**). Activation of the acoustic source at full power for data acquisition will be restricted to the AA. The acoustic source will not be operated at full power outside of the AA; however, bubble tests will take place outside of the AA but will be within the OA. Once the Seismic Vessel is outside of the OA, the acoustic source will be stowed onboard the vessel; however, streamers may still be deployed for example if the vessel is having to seek shelter.

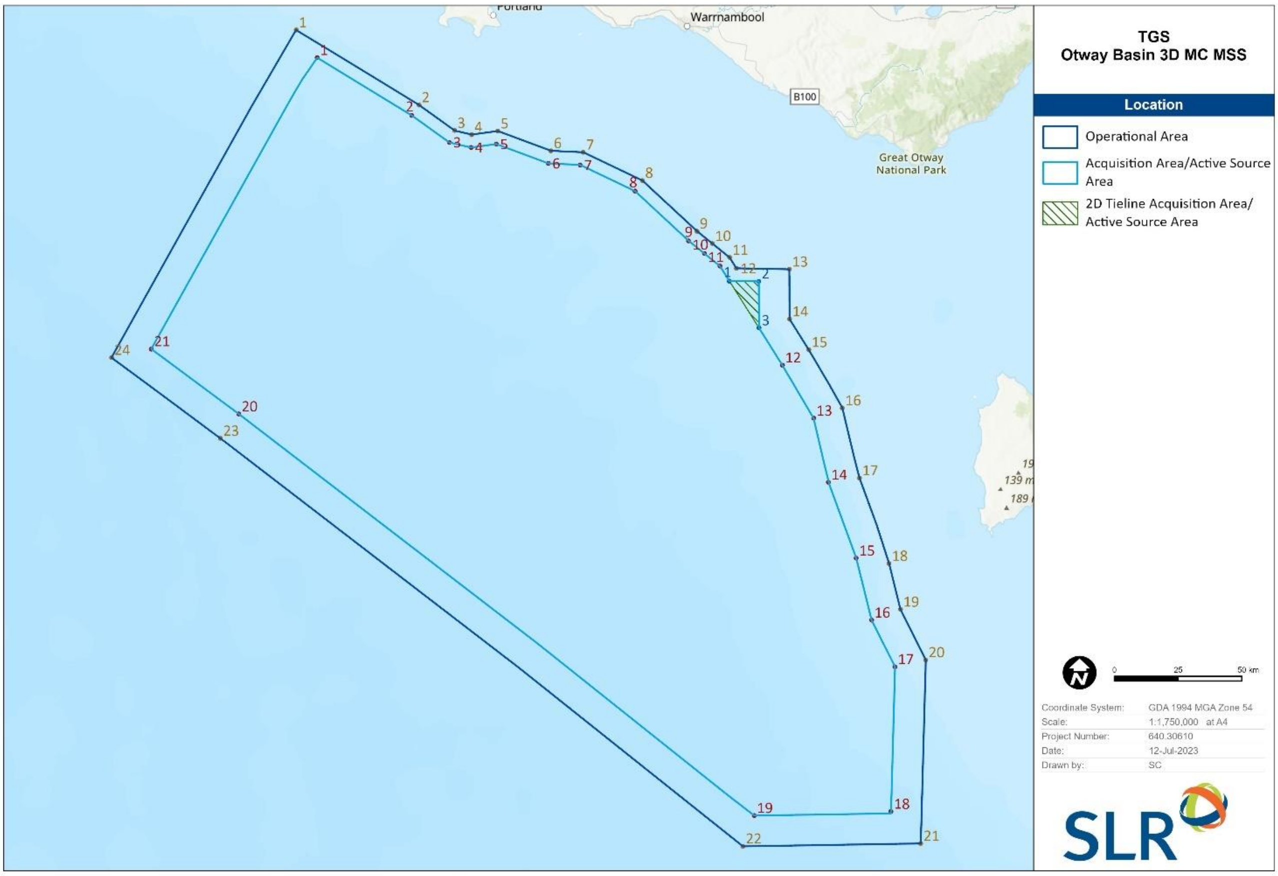

Figure 4 Location of the OA and AA

3.2.2 Acquisition Area

The AA[1] is located within the OA (see **Figure 4**) and includes areas where prospective clients may be interested in acquiring seismic data and the acoustic source will be active. This area covers approximately 45,000 km^2. Water depths within the AA range from approximately 115 m to 5,000 m; however, with the exception of the 2D tie line AA (the tie line area is defined within **Figure 4**), most of the water depths across the AA are deeper than 510 m. Soft-start procedures (**Section 3.5.3**) will occur in both OA and AA. The coordinates of the AA are provided in **Table 7**.

The seismic source may be active for short durations in the OA in a controlled manner for the purpose of source maintenance and testing. These activities are infrequent and typically involve intermittent, controlled discharges of individual source elements (i.e. single gun/cluster or single source array) for short durations and a limited number of testing shots.

During 3D seismic acquisition, the Seismic Vessel traverses the AA along a series of pre-determined parallel sail lines which are acquired in a 'race-track' pattern, whereby the Seismic Vessel turns at the end of each sail line and returns in the opposite direction along a different sail line.

[1] Note that this area is generally referred to as the Acquisition Area (AA) throughout the document, however, there is also reference to the Active Source Area. These terms are used interchangeably.

The Otway Basin 3D MC MSS requires acquisition of both 3D and 2D seismic data. The 2D tie line is to 'tie-in' to existing geophysical data in the region. The 2D tie line will overlap with 3D data acquisition in the AA; however, it will also extend onto the Continental Shelf. The acquisition of the single tie line will be limited to 12 hours of acquisition within water depths less than 500 m. At the shallowest point, the 2D tie line is in a water depth of approximately 115 m.

3.3 Timing and Duration

The Otway Basin 3D MC MSS may commence as early as 1 October 2023 (subject to acceptance of the EP) and will be completed by 30 September 2027.

The maximum acquisition time during any calendar year is 200 days, however, due to temporal controls for managing impacts to various environmental sensitivities, the duration is likely to be less. Based an analysis of the weather and sea state in the Otway Basin, seismic data acquisition is most likely to occur during the period from October to March in any calendar year covered by this EP. However, this EP does not prescribe a specific timing for seismic survey activities for the entire EP Area, as the precise timing of the survey is subject to NOPSEMA's acceptance of this EP, weather conditions, vessel availability and other operational considerations, as well as the seasonality of environmental and socio-economic sensitivities. The maximum number of days of the survey across the duration of the EP will be no more than 400 days.

To minimise survey duration, data acquisition will occur 24-hours and day, seven days per week. When recording the data, the Seismic Vessel traverses the Acquisition Area along a series of predetermined sail lines at a speed of approximately 4 – 5 knots (7 – 9 km/h), with up to 14 streamers being towed behind the Seismic Vessel (referred to herein as a 'swath'). Data for a pre-determined swath only needs to be acquired once unless there is a stop in data acquisition due to a marine mammal mitigation procedure or there is an overlap with a 2D tie line. Therefore, where no infill is required, the Seismic Vessel will not need to collect data in that area again.

Where relevant, temporal control measures are outlined in **Section 7** and **Section 8** to manage key environmental sensitivities relevant to the undertaking of seismic survey activities. The exact start and end dates of survey phases will be communicated to stakeholders, in accordance with the continuing stakeholder consultation process described in **Section 5**.

3.4 Defining Future Phase Areas

The Otway Basin 3D MC MSS may be acquired in multiple survey mobilisations over the five-year duration of the EP. The exact location and areas of individual survey phases depends upon the areas of interest from petroleum titleholders in the region.

Each individual phase of survey that may be completed under this EP will have a phase-specific AA defined, subject to the area(s) of interest at the time. Each phase of the survey will also have a phase-specific OA defined, where vessel turns, and other vessel operations may take place beyond the extent of the phase-specific AA will take place.

3.5 Otway Basin 3D MC MSS Specifications

The core activity that forms the basis of this EP is the undertaking of a MSS. Associated activities in support of undertaking the Otway Basin 3D MC MSS include refuelling and resupply, crew changes and use of support vessels in the OA. Associated activities are described in this section, as appropriate, with a focus on those considered relevant to the assessment of environmental impacts and risks.

Key details of the Otway Basin 3D MC MSS relevant to the purpose and objectives of this EP are summarised in **Table 9**.

Table 9 Key Details of the Otway Basin 3D MC MSS

Parameter	Details
Seismic Activity:	
Survey earliest commencement date	1 October 2023
Survey latest completion date	30 September 2027
Seismic Source	Double or Triple Source
Size	3,480 in^3
Pressure	2,000 pounds per square inch (psi) (nominal)
Sound source tow depth	7 m
Seismic vessel sail line speed	4.5 knots (8.3 km/hr)
Seismic source discharge interval	18.75 m (8 s – Dual Source); 12.5 m (5.4 s – Triple Source)
Streamers:	
Number of streamers	Up to 14
Streamer length	8 – 10 km
Streamer spread	800 – 1,600 m
Streamer tow depth	10 – 30 m
Vessels:	
Seismic vessel	One vessel – *specific vessel yet to be determined*
Support vessels	Two, one chase vessel and one supply/support vessel – *specific vessels yet to be determined*
Maximum single fuel tank volume	1,066 m^3
Refuelling	Refuelling at sea will occur approximately every 2 - 6 weeks (*depending on the specific vessel, contractor and weather conditions*)
Crew changes	Via helicopter, support vessel or in port approximately every 4 - 6 weeks (*depending on the specific vessel and contractor*)

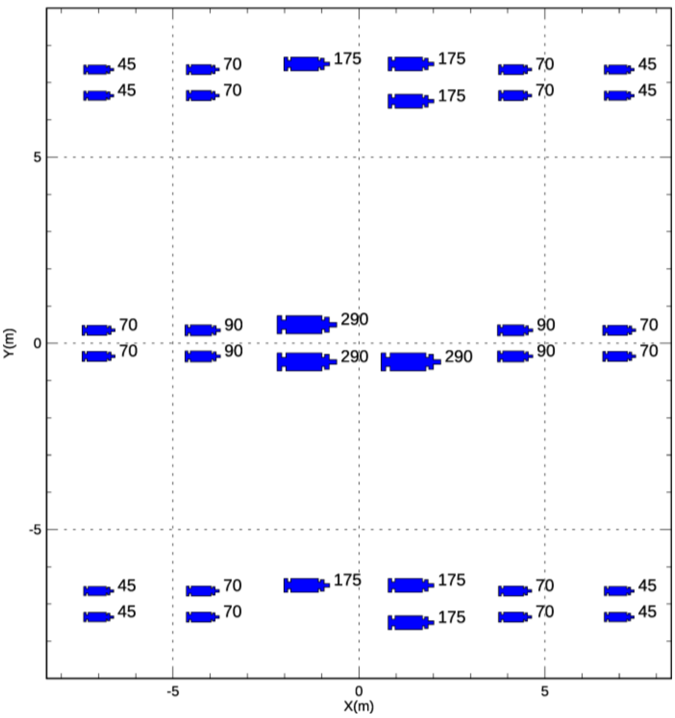
3.5.1 Acoustic Source Configuration

The Otway Basin 3D MC MSS will comprise a single Seismic Vessel towing up to 14 seismic streamers 8 – 10 km in length. The lateral spread of the streamers will be between 800 – 1,600 m. The Seismic Vessel will move at a speed of approximately 4.5 knots (8.3 km/hr).

The acquisition parameters are provided in **Table 9**, while **Figure 5** indicates the source array proposed for the Otway Basin 3D MC MSS.

Table 10 Acquisition Parameters

Parameter	Seismic Survey Parameters
Volume	3,480 in^3
Nominal working pressure	2,000 psi
Source depth	7 m
Vessel speed	4.5 knots (8.3 km/hr)
SP Interval	12.5 m
Number of streamers	Up to 14
Streamer length	8 – 10 km
Width of streamer spread	800 – 1,600 m
Streamer depth	10 – 30 m
Total expected duration	400 days, including continency



Layout of the modelled triple 3,480 in^3 acoustic source array, where the plotted layout is such that the array is centred on the origin and vessel travel direction is in the positive x-direction. The labels indicate the firing volume (in^3) for each airgun.

Figure 5 Acoustic Source Array Proposed for the Otway Basin 3D MC MSS

The acoustic source will either be a 'dual source' (comprising two source arrays discharged alternately) or a 'triple source' (comprising three source arrays discharged alternately). Each acoustic array will have an effective volume of up 3,480 in^3. The acoustic source components are attached to a hanger by chains, with the hanger attached by ropes to a surface buoy for floatation. The acoustic source arrays will be towed behind the Seismic Vessel on an umbilical line at a depth of approximately 7 m below the sea surface.

Each acoustic source component comprises two high pressure chambers: a control chamber and causes an imbalance in pressure between the two chambers. High pressure air is continuously fed to the acoustic source components from compressors onboard the Seismic Vessel. This fills the discharge chamber with high-pressure air while the piston remains in the closed position.

In order to activate the acoustic source, an electrical pulse is sent which opens a valve and forces the piston upwards. This allows the high-pressure air in the chamber to discharge into the surrounding water. The discharged air forms a spherical bubble, which oscillates according to the operating pressure, depth of operation, water temperature, and the discharge volume, ultimately forming a pressure wave. Following this discharge, the piston is forced back down to its original position by the high-pressure air in the control chamber, allowing the sequence to be repeated. The compressors are capable of re-charging the acoustic source rapidly and continuously enabling the source arrays to be fired every few seconds. The proposed firing interval for the Otway Basin 3D MC MSS is every 18.75 m (for a dual source) or every 12.5 m (for a triple source), which translates to the release of the acoustic source every eight seconds, or every 5.4 seconds, respectively.

The volume of the acoustic sources is determined by several factors, such as the objectives of the survey, the complexity of the seabed geology, and the water depths of the AA, and are designed to provide sufficient seismic energy to 'illuminate' the geological objective of the survey (OGP, 2011). TGS determined the preferred source size to be an array with a volume of 3,480 in^3, based on previous surveys in the area, and modelling exercises. This volume aligns with those used in recent marine seismic surveys and has been determined to be sufficient to achieve the goals of the Otway Basin 3D MC MSS in the deeper waters of the Otway Basin, while minimising potential impacts.

Acoustic arrays are designed to direct most of the sound energy vertically downwards, although some residual energy dissipates horizontally into the surrounding water. The amplitude of sound waves generally declines with lateral distance from the acoustic source, and the weakening of the signal with distance (attenuation) is frequency dependent, with stronger attenuation occurring at higher frequencies. The decay of sound in the sea is dependent on the local environmental conditions such as water temperature, water depth, seabed characteristics and depth at which the acoustic signal is generated.

Acoustic arrays such as those that will be utilised for the Otway Basin 3D MC MSS are designed to emit most of their energy at low frequencies, typically ranging between 10 – 300 Hz, with declining energy at frequencies above 200 Hz (APPEA 2015, Popper *et al.*, 2014). Array source sound pressure levels can range from ~241 – 265 dB peak-to-peak at one metre when measured relative to a reference pressure of one micro-Pascal (re 1 µPa m_{p-p}) (Richardson *et al.*, 1995). The overall source level amplitude of a system depends on how many elements are in each array and interaction between elements.

Peak-to-peak pressure is the primary output from the acoustic source (measured by pressure units of bar-m) caused by the expanding high pressure at release, which is measured at a stated reference point (usually 1 m from the source). Using standardised measuring protocols (peak-to-peak) and a reference point enables a comparison of the pressure produced by different acoustic sources. While the units for source level pressure are often reported in bar-m these values have little biological/environmental meaning and sound levels in the water emanating from an acoustic source involved with an MSS are more often presented as dB, calculated from peak-to-peak pressure measurements.

A detailed description of the modelled source signature determined to represent the seismic array is provided in **Section 7.2.1**, including source levels outputs with various directivity. The modelled source signature was characterised by the following maximum levels:

- Peak sound pressure level (**PK**) –258.3 dB re 1 µPa @ 1 m;
- Sound Exposure Level (**SEL**) of 233.8 dB re 1 µPa^2.s @ 1 m.

The source signature modelling enabled conversion between the different parameters (i.e. SEL vs PK), in accordance with the different metrics which define the threshold criteria for sensitive receptors. Using this information, the sound fields from single pulses and accumulated SEL are calculated and used to inform the assessment of potential effects (**Section 7.2**). This source signature simulation, including predictive source levels and directivity, was conducted using JASCOs Airgun Array Source Model and performed by JASCO (**Appendix B**).

3.5.2 Streamer Configuration

A streamer array, with terminal tail buoys, will be towed behind the Seismic Vessel (**Figure 3**). Hydrophones within the streamers detect the low-level sound waves from the acoustic source that are reflected from the geological formations below the seabed. The hydrophones convert this reflected pressure into electrical signals which are digitised and transmitted along the streamers to the recording system on-board the Seismic Vessel.

The streamer array will consist of up to 14 individual streamers, with a lateral spread of 800 – 1,600 m and will have a tail buoy of the terminal end of each streamer to mark its location (**Figure 6**). The streamers will be up to 10 km long which allow for the time delay to adequately capture signals reflected from deep, target subsurface lithologies.

The acoustic source and streamers are towed beneath the surface (**Figure 3**) as this reduces the potential for acoustic interference from the sea surface. The deeper a streamer is towed, the lower the background surface noise; however, this can also result in a narrower bandwidth of received data. TGS will have a streamer depth of 10 – 30 m. Depth is controlled from the Seismic Vessel utilising units called ‘birds’, which provide an accuracy of +/-1 m. Electronically controlled ‘wings’ on the birds pivot in response to changes in pressure (depth) as detected by a pressure transducer inside each bird, automatically pivoting the wings up or down if the streamers pull too deep or shallow (OGP, 2011).

The tail buoy (**Figure 6**) is a large hydrodynamically-shaped buoy that is towed at the terminal end of each streamer, where it serves the following functions:

- Keeping the streamer straight;
- Provides tension at the rear part of the streamer for the birds to efficiently maintain streamer depth;
- Providing a visual reference for the end of each streamer for the vessel and survey crew; and
- Holding a flag, radar reflector and flashing light and an Automated Identification System (**AIS**) transponder to allow other vessels to locate the rear of the streamers.

Each tail buoy will carry a radar reflector and flashing light to mark the end of the array. Tail buoys will also be fitted with a marine fauna deflector (also referred to as a ‘turtle guard’) on the front to ensure marine fauna, in particular marine turtles, are not injured or trapped within the tail buoy.

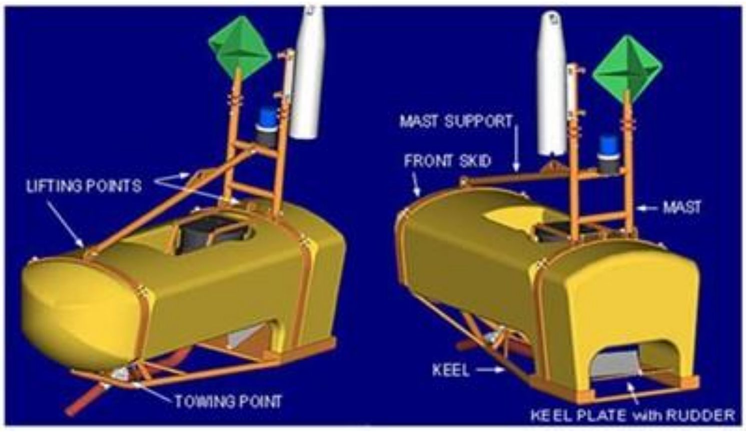


Figure 6 Example of a Seismic Streamer Tail Buoy, with Light, Radar Reflector, and AIS Transponder

3.5.3 Sail Lines, Line Turns and Infill Lines

The data for the Otway Basin 3D MC MSS will be acquired along a series of adjacent and parallel lines, referred to as 'sail lines'. As the vessel manoeuvres from a completed sail line to an adjacent un-surveyed line, the full power array will be inactive through the line turn of the 'racetrack' survey pattern. There may be some bubble tests during the line change, for example if some of the acoustic sources need to be swapped out) before commencement of the soft start procedure. The number and density of sail lines (termed the 'pre-plot') and acquisition geometry are carefully designed to allow suitable coverage of target areas within the AA, whilst optimising the efficiency of the Otway Basin 3D MC MSS.

During line runouts, the seismic source will typically be operated at full volume for the equivalent of half a streamer length (up to 4 – 5 km) before the source is shut down and the survey vessel commences the next line turn. Following completion of the line turn, the vessel will complete a run-in, which involves sailing in a straight line to allow the streamers to straighten prior to recommencing acquisition. During these run-ins, Soft-start Procedures occur for a minimum of 30 minutes (approximately 4 – 5 km), which begins with the operation of the single smallest source element in the array and gradual ramp-up to include additional source elements until the seismic source is operated at full volume for the commencement of the acquisition line. Soft-starts over a period of 30 minutes are a requirement of the EPBC Act Policy Statement 2.1. Soft-start Procedures will also be undertaken prior to commencing the Otway Basin 3D MC MSS, or after a break in the source being active.

The Seismic Vessel has limited ability to manoeuvre whilst towing the streamer and acoustic array, which is mitigated through the presence of a support vessel for the duration of the Otway Basin 3D MC MSS to ensure the area ahead of the survey vessel is clear and engage with any other marine users in the area.

During the Otway Basin 3D MC MSS, situations may arise where the acoustic source will be required to be shut-down. For example, in response to a cetacean entering the Shut-down Zone. If Shut-down Procedures are enacted, the Seismic Vessel will return to acquire the un-surveyed portion of the sail line later. These return acquisitions are termed re-shoot lines. Any infill and/or re-shoot lines required would most likely be completed on a different day.

Activation of the acoustic source along sail lines, during line turns, and when acquiring infill lines will be constrained to within the AA. The AA and associated buffer constitute the OA, as shown in **Figure 4** and as bounded by the coordinates provided in **Table 7** and **Table 8**.

3.5.4 Project Vessels

At the time of preparing this EP, no project vessels had been contracted to complete the Otway Basin 3D MC MSS. TGS will undertake a vessel audit before commencement of the Otway Basin 3D MC MSS to ensure all relevant EPSs will be met onboard the contracted vessels and any potential risks will be reduced to ALARP and Acceptable Levels. If there is any significant difference to what has been assessed, a management of change process would be undertaken (as per **Section 10.4.6**).

3.5.4.1 Seismic Survey Vessel

A purpose-built Seismic Vessel will be contracted for the Otway Basin 3D MC MSS to tow and operate the acoustic source and streamers. The specific vessel has not yet been determined. A small workboat will also be on board the seismic vessel, which may be launched to support equipment deployment, recovery and maintenance activities within the OA. The Seismic Vessel employed for the survey will use marine diesel oil (**MDO**) fuel.

3.5.4.2 Support Vessels

Two support vessels will be contracted for the Otway Basin 3D MC MSS. These vessels will be able to perform some, or all of, the following roles:

- Assist with managing potential interactions between the Seismic Vessel, the seismic array (acoustic source and streamers), and other vessels, receptors, or activities occurring in the area;
- Resupplying, refuelling and emergency towing of the Seismic Vessel; and
- Other support functions, including as a secondary vessel to assist with managing potential interactions with cetaceans and other users of the area.

At least one of the Support Vessels will be selected such that it is of a sufficient size and power to tow a Seismic Vessel in the unlikely event that the Seismic Vessel loses power.

A Support Vessel will be positioned at a safe distance from the Seismic Vessel and towed seismic array and will maintain 24-hour watch, using visual and electronic means, for other vessels or activities which might be approaching or in the path of the Seismic Vessel.

At the time of submission of this EP, the specific vessels have not been contracted. However, both vessels will be smaller than the Seismic Vessel, of suitable class for safely operating in the offshore environment comprising the OA, be crewed by competent persons, have all required operational procedures and systems in-place, and carry all required communication and safety equipment.

3.5.5 Refuelling Operations and Crew Changes

Bunkering will take place at irregular intervals as dictated by the weather (may do several close together if vessel has gone a period without ability to refuel). As above, may also be required to refuel at port if weather does not permit safe refuelling at sea

Wherever possible, crew changes and refuelling (bunkering) for the survey vessels will be undertaken at-sea. However, if environmental (weather does not permit safe refuelling at sea) or logistical issues arise, a port call may be required. To reduce the risk of a fuel spill event, at-sea refuelling operations will occur within the OA and in accordance with the control measures outlined in **Section 8.4** and **Section 8.5**.

Bunkering operations will take place at irregular intervals as dictated by the weather (i.e the Seismic Vessel may be required to undertake some bunkering operations close together if the vessel has gone a period without the ability to refuel), and crew changes will take place every four to six weeks, depending on the specific vessel and contractor. Fresh provisions will be supplied to the survey vessels at crew changes and during bunkering operations as required.

3.5.6 Helicopter

Helicopters may be utilised to transport equipment, supplies and crew to and from the Seismic Vessel during the Otway Basin 3D MC MSS, and also provide emergency medical evacuation, if required.

4 Existing Environment

This section describes the key physical, biological, socio-economic, and cultural characteristics of the existing environment and the sensitivities and receptors that may be affected, both from planned activities and unplanned events associated with the Otway Basin 3D MC MSS. Consequently, the description of the existing environment applies to two areas:

- The OA, as presented in **Figure 1** and described in **Section 3.2.1**.
- The EMBA, as shown in **Figure 7** and further described in **Section 4.1**.

4.1 Environment that May Be Affected

While most planned activities and unplanned events associated with the Otway Basin 3D MC MSS will affect the environment up to a few hundred meters from the acoustic source location, a significant unplanned event, such as a fuel oil spill from a survey vessel, has the potential to impact the existing environment substantially beyond that seen through impacts from planned events. To reflect this and capture all sensitivities that may be affected, stochastic hydrocarbon dispersion and fate modelling (see **Section 8.3.2**) was used to derive the EMBA.

TGS commissioned RPS Limited to model the oceanic dispersal and beaching potential of a hydrocarbon spill from the unlikely situation of a spill event during the Otway Basin 3D MC MSS (**Section 8.3**, **Appendix C**). This modelling simulated the occurrence of 100 realistic spill events of 1,066 m^3 of MDO from five locations within the OA over six hours on the sea surface (and randomly distributed over the previous decade). Once all 100 simulations were run per location, the results were combined to determine the maximum potential extent at which various environmental thresholds were reached, including for floating, entrained, dissolved and shoreline accumulations of hydrocarbons.

The extent of the EMBA (**Figure 7**) was based on a combination of the maximum extent of the spill trajectory at which entrained hydrocarbons were above the low threshold from each of the three modelled release locations. Utilising the maximum extent from all three spill locations results in a worst-case scenario for the spatial extent of impacts from the Otway Basin 3D MC MSS.

Acoustic modelling shows that noise levels exceeding predefined impact thresholds do not exceed the boundary of the unplanned vessel hydrocarbon spill EMBA detailed above. Therefore, the unplanned hydrocarbon EMBA represents the overall EMBA for the activities associated with the proposed Otway Basin 3D MC MSS.

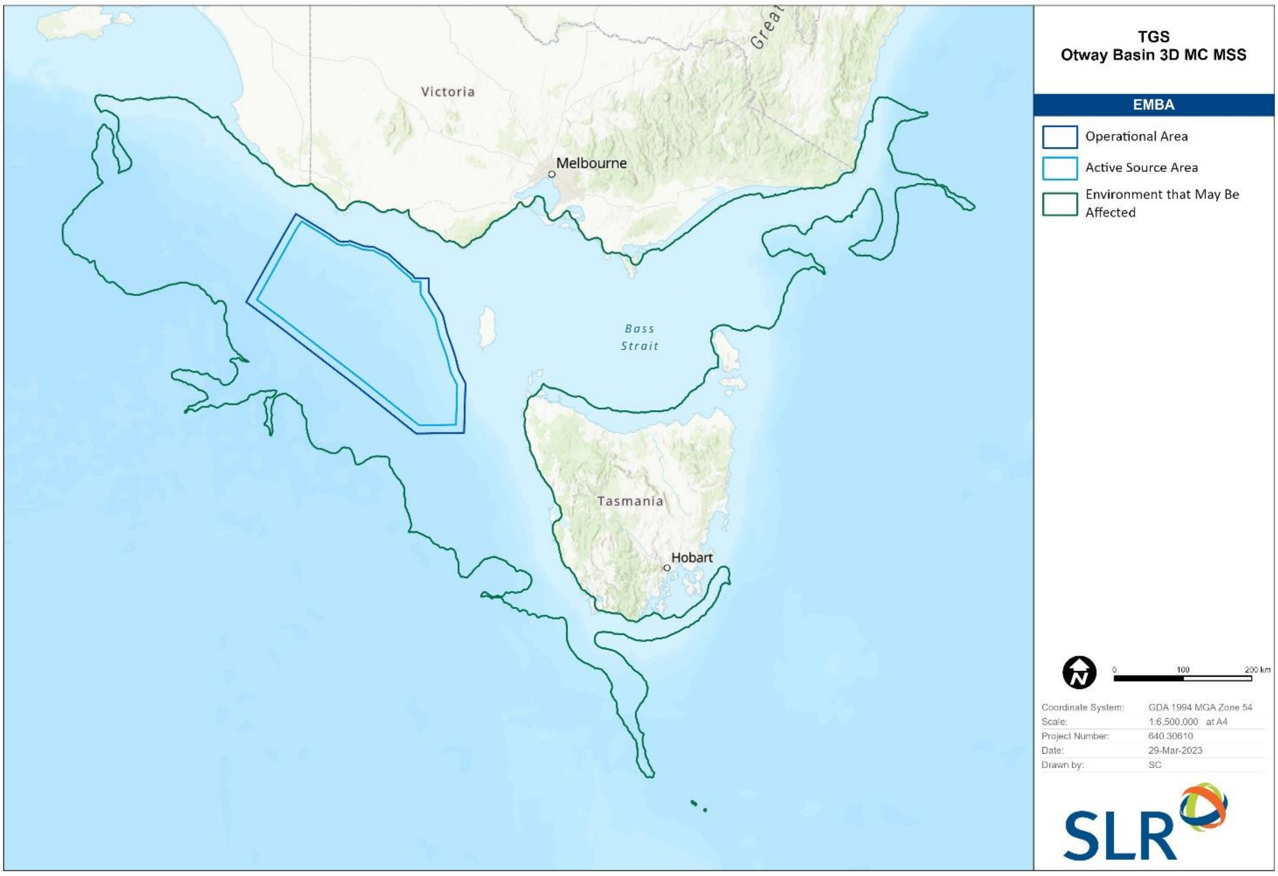

Figure 7 EMBA Associated with the Otway Basin 3D MC MSS

4.1.1 Environmental Values and Sensitivities

As required by Regulation 13(3) of the Environment Regulations, a comprehensive description of the environmental values and key sensitivities within the EMBA has been provided within this EP. Descriptions have been guided by the results of a search utilising the Protected Matters Search Tool from the Department of Climate Change, Energy, the Environment and Water (**DoCCEEW**). The full results from this search are found within **Appendix D**.

4.2 Regional Environment

4.2.1 Marine Regions

In 2008, the former Department of the Environment, Water, Heritage and the Arts (now the **DCCEEW**) introduced marine bioregional planning. Under these plans, the Australian marine environment was categorised into six broad marine bioregions. Marine Bioregional Plans have been developed for four of the six bioregions and describe the marine environment and conservation values of each marine region, set out broad biodiversity objectives, identify regional priorities and outline strategies and actions to address these priorities. The plans are intended to support ecologically sustainable use of ocean resources by marine-based industries while conserving a health and resilient marine environment.

The OA and EMBA are located within the South-East Marine Region (**SEMR**) (**Figure 8**). The EMBA also overlaps with the Temperate East Marine Region, however, this overlap only includes a couple of kilometres into the boundaries of the Temperate East Marine Region and therefore is not described further.

The SEMR incorporates Commonwealth waters extending from near the far south coast of New South Wales, around Tasmania and as far west as Kangaroo Island in South Australia. It includes the Commonwealth waters of Bass Strait and those surrounding Macquarie Island in the Southern Ocean. The SEMR is characterised by the following aspects (CoA, 2015a).

- Significant variation in water depths (60 – 6,700 m) with a number of canyons and seamounts;
- High productivity waters including the Bonney Upwelling and Bass Strait Water Cascade;
- Temperate and sub-Antarctic marine ecosystems which are home to globally significant populations of endemic and internationally threatened species;
- Containing threatened and migratory species listed under the EPBC Act, including cetaceans, pinnipeds, marine reptiles, seabirds and migratory shorebirds and sharks; and
- Containing BIAs, where protected species display biologically important behaviour such as breeding, foraging, resting or migration.

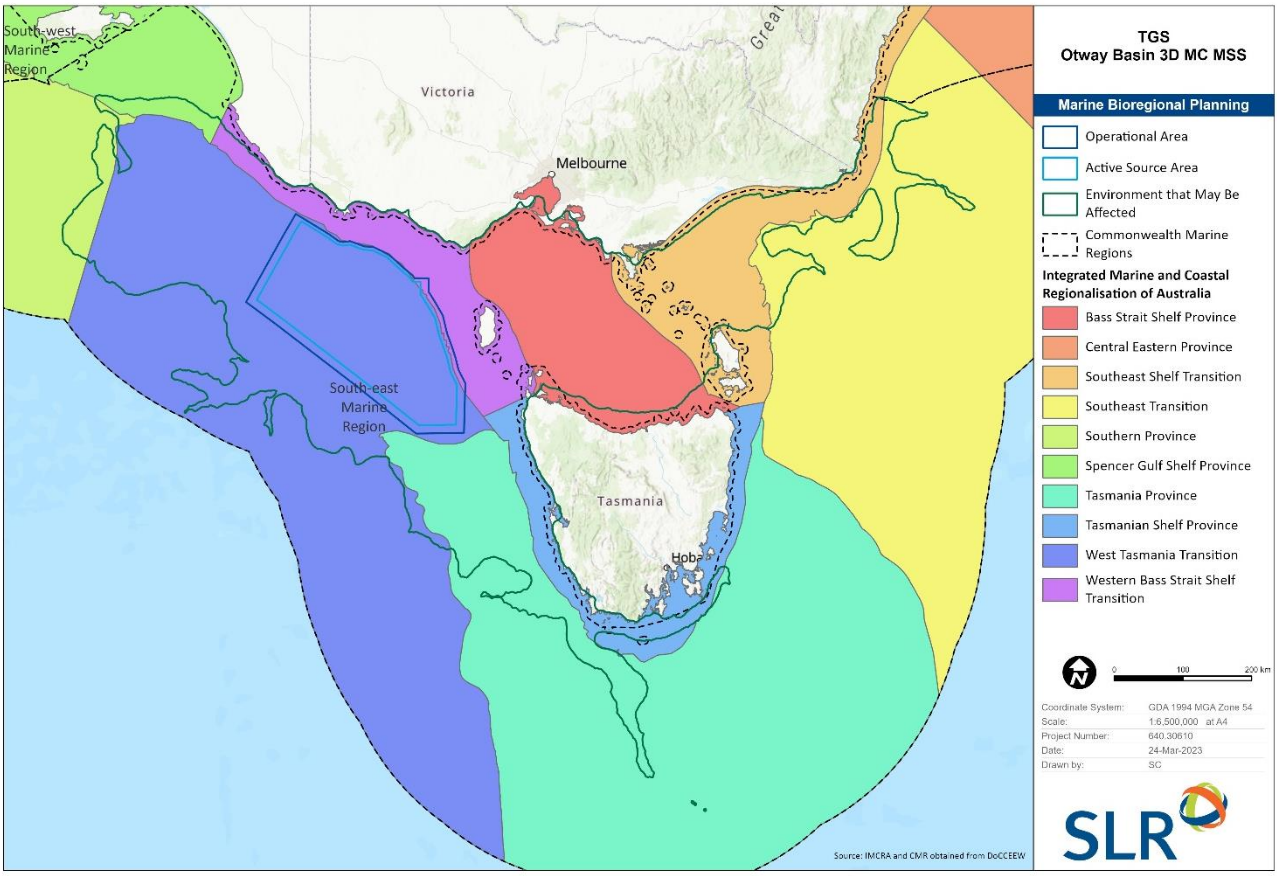

Figure 8 Marine Bioregional Planning in Relation to the OA and EMBA

4.2.2 Provincial Bioregions

The Integrated Marine and Coastal Regionalisation of Australia (**IMCRA**) is a biogeographic regionalization of Australia's marine jurisdiction based on spatial patterns in the benthic and pelagic environment and at scales appropriate to support effective marine planning. Provincial bioregions are principally based on the broad-scale distribution of demersal fish.

As seen in **Figure 8**, the OA overlaps the West Tasmania Transition and Western Bass Strait Shelf Transition. Additionally, the EMBA overlaps with nine provincial bioregions: the Bass Strait Shelf Province, Southeast Shelf Transition, Southeast Transition, Southern Province, Spencer Gulf Shelf Province, Tasmania Province, Tasmanian Shelf Province, West Tasmania Transition, Western Bass Strait Shelf Transition. A brief description of these provinces is provided in **Table 11**.

Table 11 Description of Provincial Bioregions of Relevance to the Otway Basin 3D MC MSS

Provincial Bioregion	Description
Bass Strait Shelf Province	The Bass Strait Shelf Province bioregion covers and area 96,670 km^2 on the shelf region of northern TAS and the Bass Strait. Maximum water depth within this bioregion is 90 m.
Southeast Shelf Transition	The Southeast Shelf Transition bioregion covers 175,540 km^2 of waters around Findlers, Cape Barren, and Clarke Islands across to the Australian mainland and up the east coast. Maximum water depth within this bioregion is 359 m.
Southeast Transition	The Southeast Transition bioregion is location on the southeast margin of Australia. It covers an area of 541,940 km^2 with a maximum water depth of 5,534 m.
Southern Province	The Southern Province bioregion is located off the southern margin of Australia. It covers an area of 774,120 km^2 and includes the Diamantina Fracture Zone, a region of very rugged seabed comprising numerous deep-sea ridges and troughs.
Spencer Gulf Shelf Province	The Spencer Gulf Shelf Province bioregion is located on inshore regions of Spencer Gulf on the southern margin of Australia. It covers an area of 132,860 km^2 out to a maximum water depth of 603 m.
Tasmania Province	The Tasmania Province bioregion covers an area of 300,190 km^2 on the southeast margin of Australia. Maximum water depth within this bioregion is 5,584 m. This bioregion is characterised by many seamounts that contain endemic fish.
Tasmanian Shelf Province	The Tasmanian Shelf Province bioregion is located on the shelf regions of eastern, southern and western TAS. It covers an area of 59,300 km^2 with a maximum water depth of 834 m.
West Tasmania Transition	The majority of the OA and a large part of the EMBA is located within the West Tasmania Transition, a bioregion that covers 289,850 km^2 of deeper, offshore waters of depths up to 5,645 m. The region is commercially important to both the petroleum industry and commercial fishing industry.
Western Bass Strait Shelf Transition	The most northern portion of the OA and EMBA is located within the Western Bass Strait Shelf Transition, a bioregion that covers 37,130 km^2 of water in the inshore shelf region of depths up to 272 m. The region is commercially important to both the petroleum industry and commercial fishing industry.

4.3 Physical Environment

4.3.1 Meteorology

The OA of the Otway Basin 3D MC MSS is located in the Southern Ocean, west of Tasmania. The weather systems in this temperate region are typified by cold, wet winters, and warm, dry summers. Sub-tropical high-pressure systems dominate in summer while sub-polar low-pressure systems are frequent in winter.

Typical wind patterns in the region are south-westerly in summer, and westerly in winter (Sturman, 1996). The OA is located within an area of the 'Roaring Forties', a low-pressure system that often carries strong westerly winds and cold fronts that produce strong winds from the west, north-west and south-west quarters and often result in stormy weather and large waves.

The Integrated Marine Observing System has a mooring deployed in the Bonney Coast region off Cape Bridgewater. This region has strong seasonal upwelling and supports one of the most productive regions of temperate Australian coastal waters (IMOS n.d.).

Weather stations near to the OA include Cape Otway Lighthouse, Portland (Cashmore Airport), Robe and King Island Airport. A summary of the seasonal ranges in mean temperature, rainfall and wind speeds recorded for 1991 – 2020 are presented in **Table 12**.

Table 12 Seasonal Mean Air Temperature, Rainfall and Wind Speed Ranges (1991 – 2020)

Weather Station	Distance from OA	Temperature (°C)	Monthly Rainfall (mm)	Wind Speed (km/h)
Cape Otway Lighthouse[1]	63 km northeast	13.0 – 21.3	41.0 – 119.0	20.2 – 26.7
Portland (Cashmore Airport)[2]	42 km northeast	13.2 – 22.5	30.8 – 112.5	15.2 – 25.6
Robe[3]	160 km northwest	13.9 – 22.7	18.6 – 99.5	16.0 – 26.6
King Island Airport[4]	49 km east	13.3 – 21.2	32.0 – 117.2	19.2 – 29.0

[1]BoM 2021a, [2]BoM 2021b, [3]BoM 2021c, [4]BoM 2021d. * Wind speed ranges include both 9 am and 3 pm conditions.

4.3.2 Air Quality

Air quality across the OA is expected to be high given that air flow originates in the Southern Ocean, and there are no intervening land masses that could influence the quality of air from any anthropogenic or natural terrestrial sources.

4.3.3 Oceanography

4.3.3.1 Currents

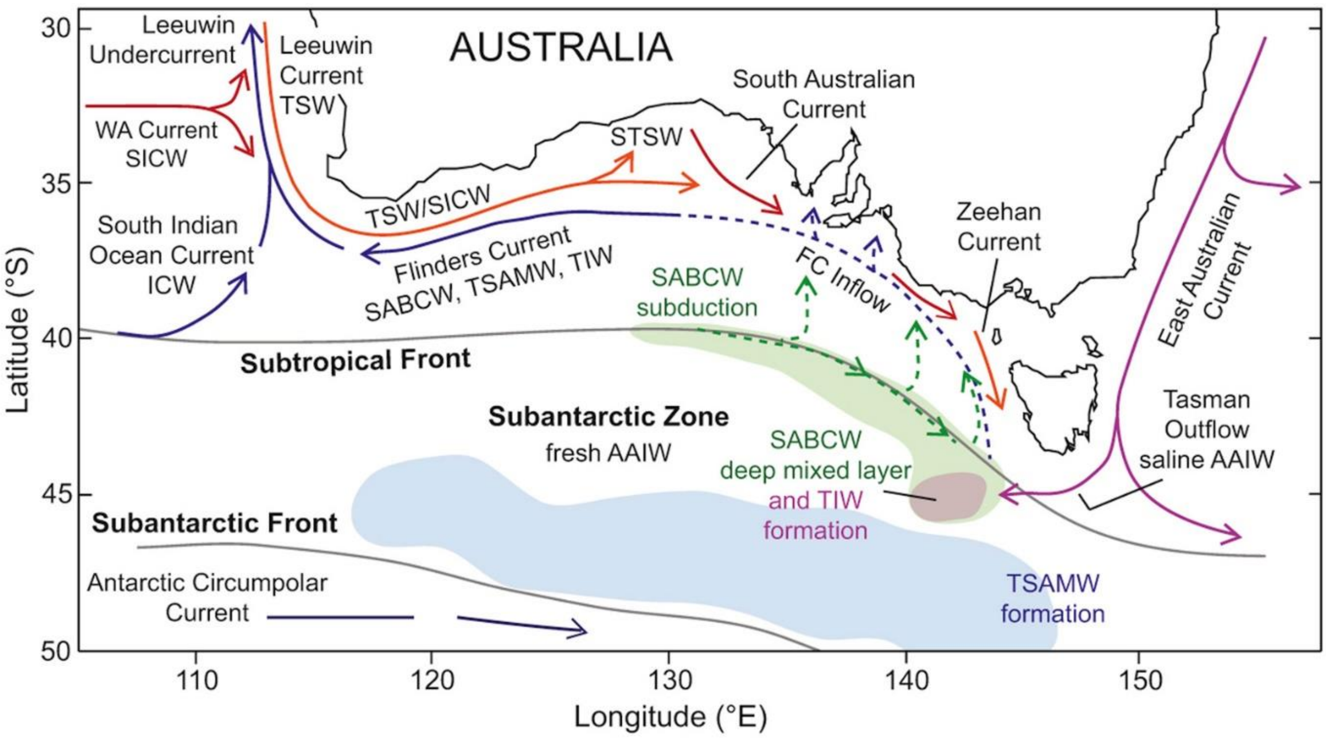
The SEMR is oceanographically complex, with subtropical influences from the north and subpolar influences from the south (CoA, 2015a). The Leeuwin Current transports warm, subtropical water southward along the Western Australian coast and then eastward into the Great Australian Bight (**GAB**) (Ridgway and Condie, 2004) where it mixes with the cool waters from the Zeehan Current running along the west coast of Tasmania. The two mixed currents continue to move east as the South Australian Current (**Figure 9**), splitting into Bass Strait and south along Tasmania's west coast, introducing warm, saline waters to the region. The Leeuwin Current exhibits considerable inter-annual variability, varying relative to coastal winds (Ridgway and Condie, 2004) and is strongest in the austral winter (Waite *et al*., 2007) when southerly winds are strongest (Deng *et al.,* 2008). The path of the Zeehan Current is consistent from year to year as a result of the bathymetric contours along the shelf break where it flows (Ridgway, 2007).

The Leeuwin Current is relatively narrow (approximately 100 km wide) and shallow (<300 m) (Rennie *et al.,* 2007), with speeds across the Great Australian Bight of approximately 0.3 – 0.5 ms^{-1} (Cresswell and Domingues, 2009). The Zeehan Current is even narrower and slower flowing, where it is approximately 40 km wide (Baines *et al*., 1983) with mean speeds of up to 0.3 ms^{-1} (Cirano and Middleton, 2003).

The westward flowing Flinders Current is described as a northern boundary current resulting from surface wind stresses (Middleton and Cirano, 2002). The Flinders Current originates in the Southern Ocean and is associated with deep upwelling over the continental shelf at depths of 600 – 1,000 m (Middleton and Platov, 2003). This current is present year-round (Middleton and Cirano, 2002; Kämpf, 2010) although it is generally strongest in the summer and weakest in winter (Middleton and Bye, 2007). The Flinders Current increases in speed from 0.05 ms^{-1} in the east to 0.2 ms^{-1} in the west where it meets the Leeuwin Current in winter.

The eastern parts of the SEMR are strongly influenced by the East Australian Current (**EAC**) that flows southward adjacent to the east coast of New South Wales (**NSW**), VIC and TAS, carrying warm equatorial waters (**Figure 9**). The EAC is up to 500 m deep and 100 km wide and is strongest in summer when it can flow at up to 5 knots (~9 km). In winter the EAC flows at 2 – 3 knots (~3.5 - 5.5 km) as the oceanographic and climatic drivers in the Coral Sea diminish (CoA, 2015a). The EAC affects sea surface temperatures on the eastern Tasmanian shelf, which can vary substantially among years depending on the relative influence of subtropical waters (CoA, 2015a).

The waters around Macquarie Island to the south of Tasmania are in the path of the Antarctic Circumpolar Current (**ACC**) (**Figure 9**); the largest single current in the world and considered to be a major driver of global climate. The ACC connects the Atlantic, Pacific and Indian Oceans in an eastward flow. The ACC contains a series of jets that continuously combine and separate, acting as a buffer between different masses of water. In summer the ACC is south of Tasmania, which allows the EAC to extend its flow around southern Tasmania. In winter the ACC passes closer to Tasmania and its comparative strength prohibits a weakened EAC from flowing further southward. The interaction of these currents, fronts and sea-floor features influence species composition, distribution, and dispersal, controlling the movement of sediments and nutrients and the seasonal variations in salinity and temperature (CoA, 2015a).



Key: STSW = Subtropical surface water, SABCW = South Australian Basin central water, TSAMW – Tasmanian subantarctic mode water, TIW = Tasmania intermediate water, TSW = Tropical surface water, SICW = South Indian central water, ICW = Indian central water, AAIW = Antarctic intermediate water

Figure 9 Major Ocean Currents Along the Southern Australian Coastline

4.3.3.2 Tides

Tides in the Otway Basin are semi-diurnal with some diurnal inequalities (Jones and Pradman, 1983). The maximum range of spring tides in western Bass Strait is approximately 1.2 m. Sea level variation in the area can arise from storm surges and wave set up (Santos, 2004).

Bass Strait is a relatively shallow area on the continental shelf, connecting the southeast Indian Ocean with the Tasman Sea. The Bass Strait is recognised as an area of strong tidal currents, which are primarily driven by tides, winds and density-driven flows. The tides of central Bass Strait are semi-diurnal with the dominant large-scale water movements due to the astronomical tide (Jones, 1980). The tidal waves enter Bass Strait from the east and west almost simultaneously and as a result in the centre of the strait there is an area with small tidal currents where the two waves meet. The magnitude of the tidal currents then increases as the distance from the central strait increases with relatively strong tidal currents at either end. The times and magnitudes of the tide within Bass Strait are relatively uniform and predictable. However, the effects of meteorological phenomena may be significant, causing variations in level and changing the phasing or timing of the tide (Sandery and Kampf, 2005).

4.3.3.3 Waves

Due to the relatively wide and shallow continental shelf of the SEMR, the coast is subject to large storm surges. There are two principal sources of wave energy in the Otway Basin:

- The westerly swell from the GAB and Southern Ocean; and
- Locally generated winds, generally from the west and east.

Wave heights range from 1.5 m to 2 m separated with periods of 8 s to 13 s. Heights of 5 m to 7 m, and up to 10 m can occur during storm events. The Cape Bridgewater wave buoy recorded the lowest wave height for 2020 as 0.78 m (January) and the maximum wave height as 7.93 m (May). The largest waves are associated with eastward-moving low pressure and frontal systems that in winter cross the region every 4 to 6 days.

4.3.3.4 Upwellings

The waters of the SEMR are relatively low in nutrients and primary productivity compared to other marine regions. However, in some locations, water bodies converge and mix to create areas of relatively high biological productivity (DNP, 2013). Seasonal and transient upwellings are an important feature of the SEMR and include the Bonney Upwelling in south-eastern SA, and the Bass Strait Water Cascade on the shelf break east of Bass Strait (CoA, 2015a).

The Bonney Upwelling is the largest and most predictable upwelling in southeast Australia and is present throughout summer months (November to March) (Butler *et al*., 2002). The upwelling is driven by seasonal movements of a subtropical ridge that lies over the Great Australian Bight in summer and pushes southeast winds along the Bonney Coast which interact with regional ocean circulation and climate patterns (as referenced in Nieblas *et al*., 2009). Open ocean waters are moved onto the continental shelf resulting in a shallow thermocline (with increased nutrient concentrations below (Nieblas *et al*., 2009). Within the Bonney Upwelling there are 2 – 3 major upwelling events, each lasting approximately one week (Kämpf *et al.*, 2004). The highly productive Bonney Upwelling system provides a feeding ground for a number of cetaceans (particularly blue whales), pinnipeds, seabirds, and fish, and is important to a number of fisheries (e.g. rock lobster) (Butler *et al*., 2002).

The Bass Strait Water Cascade is a down-welling current originating in the shallow waters at the shelf break east of Bass Strait. The cascade flows down the continental slope into the Tasman Sea (Tomczak, 1987). Winter cooling of the saline waters within Bass Strait forms water that is denser than the adjacent Tasman Sea (Middleton and Cirano, 2005). Water cascades to depths of 300 m or more (Middleton and Cirano, 2005), with the down-flow of denser water creating high-salinity intrusions along the continental slope (Tomczak, 1987). Fish and whales are known to aggregate in these nutrient-rich waters (CoA, 2015a).

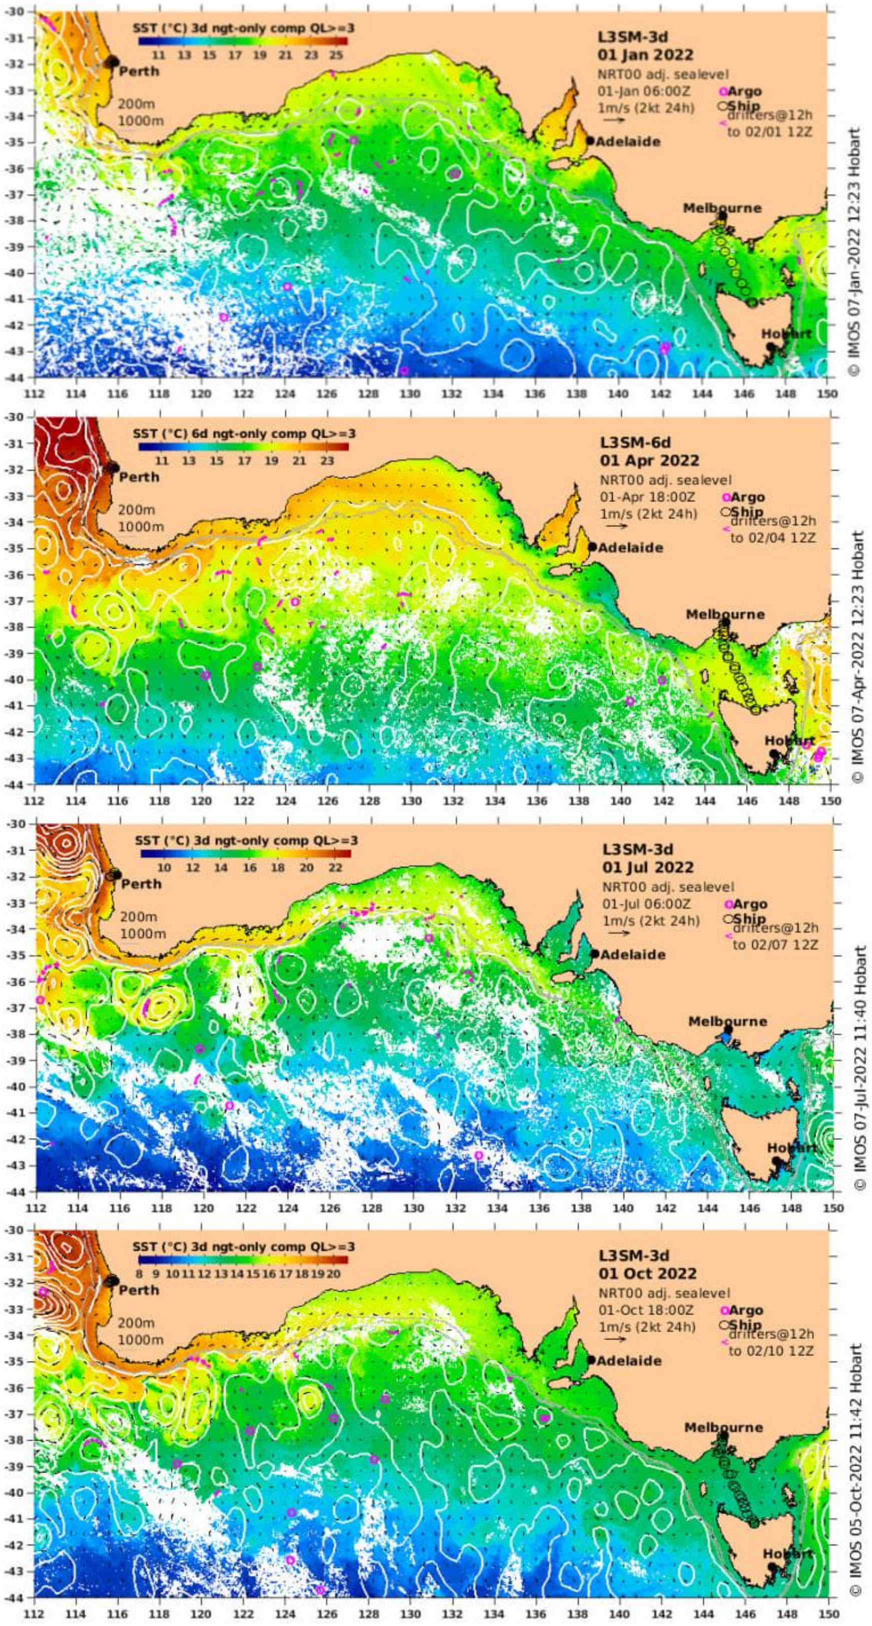
4.3.3.5 Thermoclines and Sea Temperature

Thermoclines occur when cold and relatively warm water separate vertically in the water column and often develop because of solar heating of the upper water column during warmer months. Stratification profiles vary with local environmental conditions; for example, storm conditions can cause significant vertical mixing and breakdown of the thermal structure, and local tides and currents can either enhance or damage the structure of the thermocline. Consequently, a well-defined thermocline is not always present.

Thermoclines can be observed through processed seismic data. A thermocline is characterised by a negative sound speed gradient and can be acoustically reflective. This is a result of a discontinuity in the acoustic impedance of water created by the sudden change in density resulting from the temperature difference. A temperature change of 1°C can result in a change in the speed of sound of 3 ms^{-1} (Simmonds *et al*., 2004).

In the Otway Basin, the winter thermocline intersects the seafloor at the shelf edge caused by deep cold water from the Flinders Current moving northward along the continental slope at the same time as surface warm water from the Leeuwin Current move from west to east (Boult *et al*., 2006). In the summer, the strength of the Leeuwin Current decreases and the Flinders Current becomes more dominant, causing the thermocline to move onto the Continental Shelf (Boult *et al*., 2006).

Sea surface temperatures vary seasonally. Real-time temperatures recorded in 2022 are presented in **Figure 10**. Water temperatures in the Otway Basin range from 12 °C (Spring) to 19° C (Summer) (IMOS, 2023). Minimum water temperatures are reached in the spring, in line with an increased in cold, high productivity waters of the Bonney Upwelling (see **Section 4.3.3.4**).



Graphs represent 2022 data for Summer (January), Autumn (April), Winter (July), and Spring (October)

Figure 10 Seasonal Sea Surface Temperature for the Otway Basin

4.3.4 Geomorphology and Bathymetry

The seafloor of the OA varies greatly, but in general covers three seabed types; the continental shelf, deep, and slope between the two (Welch *et al*., 2023). Water depths in the OA range from approximately 95 m to 5,650 m (**Figure 11**). The shelf is narrow (10 – 25 km wide) along the coast of South Australia, VIC and TAS, but widens within the Bass Strait. There are numerous sea-floor canyons along the continental margin throughout the region. Many of these are identified as Key Ecological Features (**KEF**) (**Section 4.4.3**). **Table 13** and **Figure 12** describe the geomorphic features located within the OA (based on IHO, 2001).

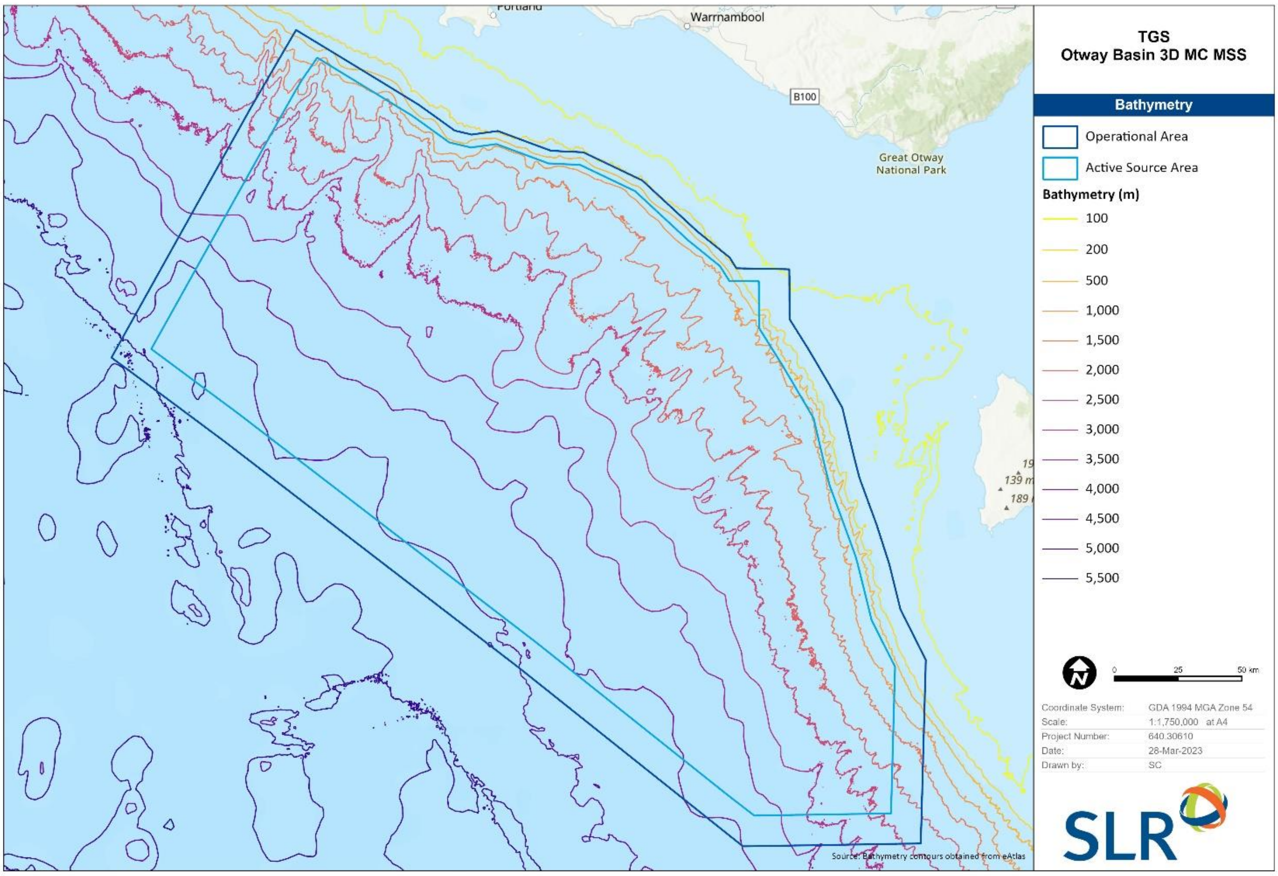

Figure 11 Bathymetry in the OA

Table 13 Geomorphic Features Located Within the OA

Geomorphic Feature	Definition
Canyon	A relatively narrow, deep depression with steep sides, the bottom of which generally has a continuous slope, developed characteristically on some continental slopes.
Shelf	A zone adjacent to a continent (or around an island) and extending from the low water line to a depth at which there is usually a marked increase of slope towards oceanic depths.
Slope	A slope seaward from the shelf edge to the upper edge of a continental rise or the point where there is a general reduction in slope.
Plateau	A flat or nearly flat area of considerable extent, dropping off abruptly on one or more sides.
Knoll	A relatively small, isolated elevation of a rounded shape.
Valley	A relatively shallow, wide depression, the bottom of which usually has a continuous gradient. This term is generally not used for features that have canyon-like characteristics for a significant portion of their extent.
Abyssal-plain/deep ocean floor	An underwater plain on the deep ocean floor, usually found at depth between 3,000 m and 6,000 m.

Source: IHO, 2001.

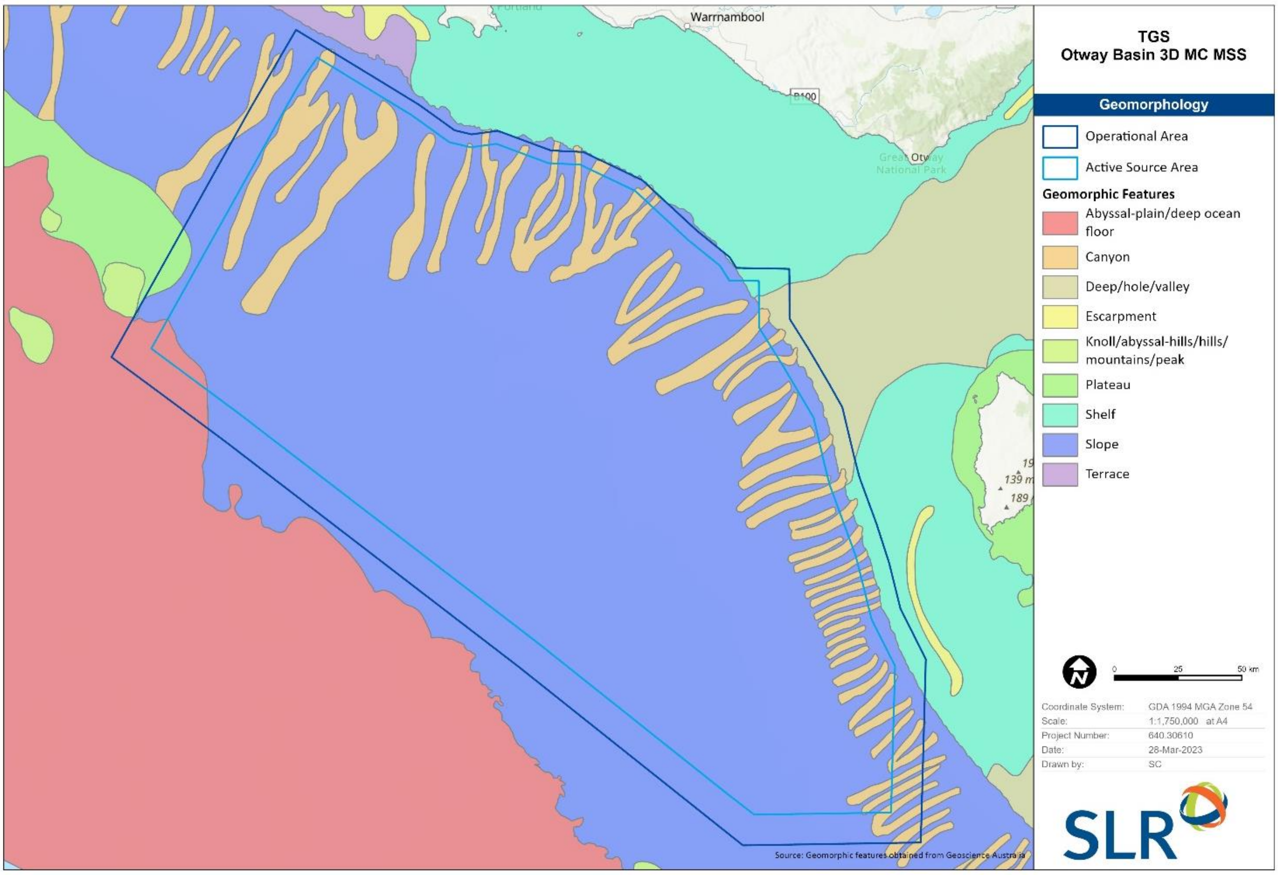

Figure 12 Geomorphic Features within the OA

4.3.5 Geology

The OA lies over the Late Jurassic-Cenozoic Otway Basin which was formed by multi-stage rift-sag and inversion phases (Geoscience Australia, 2018). The main rock types are siliciclastic sediments, sedimentary and carbonate rocks – various sandstones, shales, and mudstones. The Basin's depositional environment is mainly marine in Late Cretaceous and Cenozoic origin, with sediment thickness up to 13 km (Geoscience Australia, 2018).

The Otway Continental Shelf has sediment and sedimentary rock. Coastal sediment sources include recent basaltic rock and carbonate sediment; both lithologies are present below sea level, both on the shallow shelf and as reefs. Unconsolidated seabed sediments are generally carbonate sands (Barton *et al.*, 2012; Murray-Wallace and Woodroffe, 2014). The shelf environment has approximately shelf-edge parallel distribution of surficial sediment facies, with two main facies present. The inner shelf is dominated by hard substrate and palimpsest quartz, bivalve and bryozoan gravels. Unconsolidated sediment cover in this zone is thin or absent (James and Bone, 2011; James *et al.,* 1992). The mid-shelf is dominated by bryozoan sand (Boreen *et al.,* 1993; Harris *et al.,* 2000).

Substrates of the continental shelf (30 m – 180 m) within the OA are expected to be characterised by carbonate sands progressing from coarse to fine with increasing depth, interspersed with low profile limestone outcrops. The seabed of the shelf edge and slope (180 m - >500 m) is expected to consist of muddy carbonate sands and rocky reefs, which disappear with depth (Williams *et al*., 2009). The shelf edge is intersected by canyons and gullies consisting of unconsolidated sediments. The OA overlaps with the sea-floor canyons along the continental margin which is composed of rich organic sediment and debris.

4.3.6 Ambient Noise

Within the marine environment, ambient noise is characterised by a mix of anthropogenic and natural sounds, with the latter broken down into physical sources such as wave activity, rain, tidal turbulence, movement of sediments on the seabed and earthquakes, and biological sources such as fauna that produce sound. Consequently, ambient noise levels will vary spatially and temporally based on their prevailing environmental characteristics including between deep waters versus coastal waters and across different diel cycles (Cato and McCauley, 2002; Harland *et al.*, 2005).

Ambient noise levels throughout the OA are expected to be predominantly associated with natural sources, such as wind and wave movement, seabed sediment movements, and sound-based communications of marine fauna.

The main anthropogenic noise throughout the OA is expected to be associated with commercial vessels along the main shipping routes, in addition to commercial fishing and recreational vessels. The nearest point sources of 'industrial' noise are associated with the existing offshore gas fields shoreward of the OA (see **Section 4.7.5**). The main shore-based sources of industrial noise are at Portland (VIC), where the Alcoa Aluminium Smelter operates (approximately 41 km from the nearest point of the OA), and the Port of Portland which handles the import and export of bulk commodities.

Although measurements of underwater ambient noise levels in the OA are not available, levels can be inferred from other deep-water areas with comparable shipping activity levels. For much of the world's oceans, low frequency noise (10 to 500 Hz) due to distant shipping and wind noise dominates the overall ambient noise environment. At 1,000 m depth at a generalized deep-water site low frequency spectral noise levels range from a minimum of about 60 dB re 1 $\mu Pa^2 Hz^{-1}$ (in the absence of shipping, with low wind) up to around 90 dB re 1 $\mu Pa^2 Hz^{-1}$ with distant shipping (Hildebrand, 2009).

4.4 Marine Protected Areas and Sensitive Areas

4.4.1 Australian Marine Parks

The Australian Marine Park (**AMP**) Network has been established around Australia as part of the National Representative System of Marine Protected Areas which has the primary goal of establishing and effectively managing a comprehensive, adequate, and representative system of marine parks to contribute to the long-term conservation of marine ecosystems and protect marine biodiversity.

In accordance with the EPBC Act, the AMP Network, and any zones within it, must be assigned to an International Union for Conservation of Nature (**IUCN**) Category consistent with the management intent and objectives for that site. IUCN categories include the following:

- Ia – Strict Nature Reserve, no resource extraction;
- Ib- Wilderness Area, First Nations traditional harvesting and collection for scientific research allowed;
- II- National Park, First Nations traditional harvesting and collection for scientific research allowed;
- III – Natural Monument or Feature, First Nations traditional harvesting and collection for scientific research allowed;
- IV – Habitat/species Management Area, sustainable resource extraction allowed;
- V- Protected Landscape or Seascape, sustainable resource extraction allowed;
- VI- Protected Areas with Sustainable Use of Natural Resources, sustainable resource extraction allowed; and
- Y – Assigned, pending further information.

The OA overlaps two AMPs and the EMBA overlaps with a further eight AMPs. These AMPs are depicted in **Figure 13**, and a summary of the environmental, social and cultural values identified for each AMP are described in **Table 14** in accordance with the South-East Marine Reserves Network Management Plan 2013 - 23[2] (DNP, 2013) and the South-West Marine Parks Network Management Plan 2018 (DNP, 2018).

[2] The South-east Commonwealth Marine Reserves Network Management Plan 2013 – 2023 came into effect on 1 July 2013 and is due to expire in June 2023. As a result, Parks Australia is preparing a new management plan for the South-east Network, with the public consultation period closing on 22 May 2023. The South-east Network will continue to be managed under the current management plan until a new management plan is finalised.

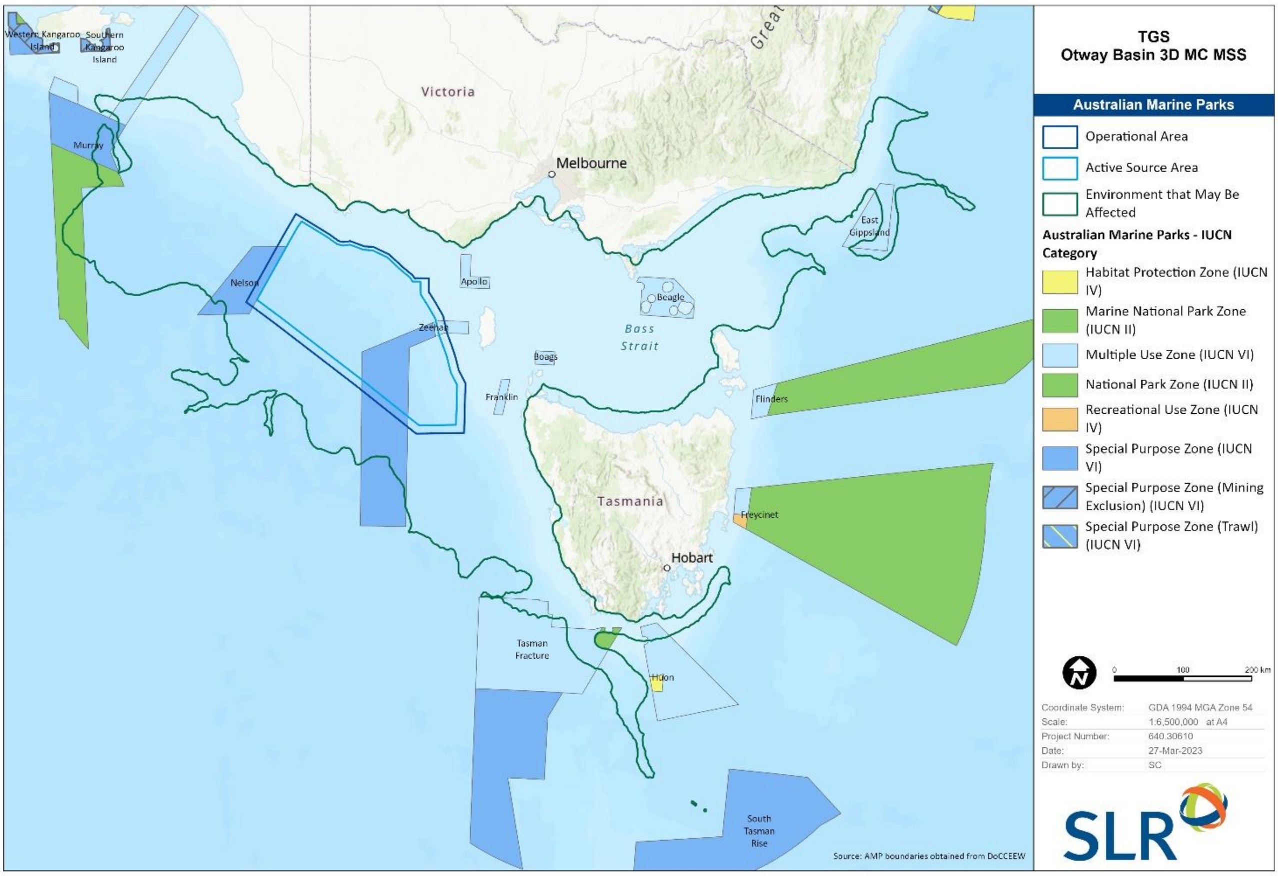

Figure 13 Australian Marine Parks of Relevance to the OA and EMBA

Table 14 Summary of Australian Marine Parks of Relevance to the OA and EMBA

AMP	IUCN Categories	Description	Values
South-east Marine Parks Network			
Zeehan AMP Overlaps with OA and EMBA	Special Purpose Zone (IUCN VI) Multiple Use Zone (IUCN VI)	Zeehan AMP is located south-west of King Island and covers four undersea canyons cutting into the continental shelf (i.e. the West Tasmanian Canyons KEF – **Section 4.4.3**). The Zeehan AMP covers an area of approximately 19,897 km^2, with water depths of 50 m to over 3,000 m. Zeehan AMP is a nursery ground for blue warehou and ocean perch, with concentrations of larval fish of these species found within the marine park. Tasmanian giant crabs are also found in the marine park, making their home in rock limestone continental shelf habitat. Benthic communities found within this region include large sponges, lace corals and other sessile filter feeders.	Examples of ecosystems, habitats, and communities associated with the Tasmania Province, the West Tasmania Transition, and the Western Bass Strait Shelf Transition. Associated with the following seafloor features: abyssal plain/deep ocean floor, canyon, deep/hole/valley, knoll/abyssal hill, shelf, and slope. Important migration area for blue and humpback whales. Important foraging area for black browed, wandering, and shy albatrosses, and great-winged and cape petrels.
Nelson AMP Overlaps with OA and EMBA	Special Purpose Zone (IUCN VI)	Nelson AMP lies approximately 200 km south of SA, beyond the edge of the continental shelf. It consists of rocky knolls, canyons, plateaus, and plains. The AMP covers an area of approximately 6,123 km^2, with water depths below 3,000 m. The waters within and surrounding Nelson AMP are recognised as valuable recreational and commercial fishing grounds for open water fishes, including species of tuna and mackerel. The near-surface waters of Nelson AMP provide an area for whales (i.e. humpback, fin, blue and sei) to commute through the AMP on their way to/from breeding and feeding grounds, and is therefore referred to as a 'whale super-highway'.	Examples of ecosystems, habitats and communities associated with the West Tasmanian Transition. Associated with the following seafloor features: abyssal plain/deep ocean floor, canyon, knoll/abyssal hill, plateau, slope. Important migration area for humpback, blue, fin and sei whales.

AMP	IUCN Categories	Description	Values
Apollo AMP 46 km to OA Overlaps EMBA.	Multiple Use Zone (IUCN VI)	Apollo AMP is located south of Cape Otway and protects an area of continental shelf at the entrance to Bass Strait. It covers an area of approximately 1,184 km^2. It is a shallow water (15 – 20 m) zone that is characterised by intermittent rocky reefs and sandy patches. Apollo AMP is an important area for foraging seabirds; Australian gannet, shy albatross, black-browed albatross, and short-tailed shearwater. Benthic assemblages are dominated by sponges, macroalgae and deep-water corals, as well as mobile macro-invertebrates such as lobsters (Lerodiaconou, 2020). An historic shipwreck, *MV City of Rayville*, lies within this AMP near Cape Otway (**Section 4.6.2**).	Ecosystems, habitats and communities associated with the Western Bass Strait Shelf Transition and the Bass Strait Shelf Province. Associated with seafloor features: deep/hole/valley, and shelf. Important migration area for blue, fin, sei, and humpback whales. Important foraging area for black-browed and shy albatross, Australasian gannet, short-tailed shearwater, and crested tern. Cultural and heritage site: wreck of the *MV City of Rayville*.
Franklin AMP 42 km to OA Overlaps EMBA.	Multiple Use Zone (IUCN VI)	Franklin AMP is located off the north-west corner of Tasmania. It includes a 150 m deep valley etched into an otherwise shallow seafloor. This AMP covers an area of approximately 671 km^2, with water depths from 40 – 150 m. Franklin AMP is an important foraging area for thousands of seabirds from the colonies on nearby Albatross Island, Black Pyramid Rock, and other Hunter Group Islands, including Australasian gannet, shy albatross, and short-tailed shearwater.	Examples of ecosystems, habitats, and communities associated with the Tasmanian Shelf Province, and the Western Bass Strait Shelf Transition. Associated with seafloor features: shelf, deep/hole/valley, escarpment, and plateau. Important foraging area for shy albatross, short-tailed shearwater, Australasian gannet, fairy prion, little penguin, common diving petrel, black-faced cormorant, and silver gull.

AMP	IUCN Categories	Description	Values
Boags AMP 105 km to OA Overlaps EMBA.	Multiple Use Zone (IUCN VI)	Boags AMP is north of Three Hummock Island off Tasmania's north-west coast. It covers an area of approximately 537km^2, with depths from 40 – 80 m. The shallowest waters of the Boags AMP are home to rick arrays of animals that live on the seafloor and in the sediment, including crustaceans, molluscs and bristle worms. Boags AMP is an important foraging area for several seabirds including shy albatross, fairy prion, black-faced cormorant, common diving petrel and little penguin. Boags AMP is on the migration route for the critically endangered orange-bellied parrot as they fly across Bass Strait in Spring and Summer.	Ecosystems, habitats, and communities associated with the Bass Strait Shelf Province. Associated with seafloor features: plateau, and tidal sandwave/sandbank. Important foraging area for shy albatross, Australasian gannet, short-tailed shearwater, fairy prion, black-faced cormorant, common diving petrel, and little penguin.
Murray AMP 232 km to OA Overlaps EMBA.	Marine National Park Zone (IUCN II) Multiple Use Zone (IUCN VI) Special Purpose Zone (IUCN VI)	Murray AMP lies south and east of Kangaroo Island and includes the Murray Canyon. The AMP connects the Murray River to the deep ocean. Murray AMP covers an area of approximately 25,803km^2, with depths from shallow continental waters down to 4,600 m. Murray AMP is an area of high productivity, boosting high marine life of seabirds and whales.	Examples of ecosystems, habitats and communities associated with the Spencer Gulf Shelf Province, the Southern Province, and the West Tasmanian Transition. Associated with sea-floor features: abyssal plain/deep ocean floor, canyon, escarpment, knoll/abyssal hill, shelf, slope, and terrace. Features with high biodiversity and productivity: Bonney coast upwelling, and shelf rocky reefs and hard substrate. Important foraging areas for: blue, sei and fin whales, Australian sea lion, wandering, black-browed, yellow-nosed, and shy albatross, great-winged petrel, flesh-footed and short-tailed shearwater, and white-faced storm petrel. Important breeding area for southern right whale. Important migration area for humpback whale.

AMP	IUCN Categories	Description	Values
Huon AMP 384 km to OA Overlaps EMBA.	Habitat Protection Zone (IUCN IV) Multiple Use Zone (IUCN VI)	Huon AMP is located south-east of Tasmania. It covers a broad depth range from the inner continental shelf at about 70 m, to abyssal depths of more than 3,000 m. Most of the AMP is in deep water.	Examples of ecosystems, habitats and communities associated with the Tasmanian Shelf Province, and the Tasmania Province. Associated with sea-floor features: canyon, knoll/abyssal hill (seamount), pinnacle, saddle, shelf, and terrace. Features with high biodiversity and productivity: seamounts south and east of Tasmania. Important foraging area for: black-browed, Buller’s and shy albatross, great-winged petrel, short-tailed shearwater, fairy prion, Australian fur seal, and orca. Important migration area for humpback whale.
Tasman Fracture 420 km to OA Overlaps EMBA.	Marine National Park Zone (IUCN II) Multiple Use Zone (IUCN VI)	Tasman Fracture AMP extends south-west of Tasmania from the continental shelf to Australia’s exclusive economic zone boundary, 200 nm from land.	Examples of ecosystems, habitats and communities associated with the Tasmania Province, Tasmanian Shelf Province, and the West Tasmania Transition. Associated with sea-floor features: abyssal plain/deep ocean floor, basin, canyon, knoll/abyssal hill, pinnacle, plateau, ridge, saddle, shelf, slope, terrace, and trench/trough. Important migration area for humpback whales. Important foraging areas for: New Zealand fur seal, wandering, black-browed and shy albatross, white-chinned petrel, common diving petrel, short-tailed shearwater, fairy prion, and white shark.

AMP	IUCN Categories	Description	Values
Beagle AMP 274 km to OA Overlaps EMBA.	Multiple Use Zone (IUCN VI)	Beagle AMP lies entirely within Bass Strait, with its north-western edge abutting VIC waters south-east of Wilson's Promontory. It is a shallow-water AMP surrounding a collection of Bass Strait islands. Beagle AMP represents an area of shallow continental shelf ecosystems in depths of approximately 50 – 70 m that extend around south-eastern Australia to the east of TAS. The seafloor that it covers formed a land bridge between TAS and VIC during the last ice age (10,000 years ago).	Ecosystems, habitats, and communities associated with the Southeast Shelf Transition. Associated with sea-floor features: basin, plateau, shelf, and sill. Important migration and resting on migration area for southern right whale. Important foraging area for: Australian fur seal, orca, shy albatross, Australasian gannet, short-tailed shearwater, pacific, and silver gulls, crested tern, common diving petrel, fairy prion, black-faced cormorant, little penguin, and white shark. Cultural and heritage sites: the wreck of the steamship *SS Cambridge* and the wreck of the ketch *Eliza Davies* (**Section 4.6.2**).
East Gippsland AMP 586 km to OA Overlaps EMBA.	Multiple Use Zone (IUCN VI)	East Gippsland AMP contains representative samples of an extensive network or canyons, continental slope, and escarpment at depths from 600 m to more than 4,000 m.	Examples of ecosystems, habitats and communities associated with the Southeast Transition. Associated with sea-floor features: abyssal plain/deep ocean floor, canyon, escarpment, knoll/abyssal hill, and slope. Features with high biodiversity and productivity: Bass Cascade and upwelling east of Eden. Important foraging area for wandering, black-browed, yellow-nosed and shy albatrosses, great-winged petrel, wedge-tailed shearwater, and cape petrel. Important migration area for humpback whale.

4.4.2 State Marine Parks, Marine National Parks, Marine Sanctuaries, Marine Reserves and Fisheries Research Areas

There are no State protected areas within the OA; however, several State protected areas within TAS, VIC, NSW and South Australia occur within the wider EMBA. These are listed within **Table 15**. Due to the number of areas of relevance to the EMBA, a map showing the location of each area has not been provided.

Table 15 State Protected Areas of Relevance to the EMBA

Area Type	Protected Area
VIC State Protected Areas	
Conservation Park	Bay of Islands Coastal Park, Cape Conran Coastal Park, Cape Liptrap Coastal Park, Discovery Bay Coastal Park.
Heritage River	Aire River, Bemm, Goolengook, Arte and Errinundra Rivers, Glenelg River.
Indigenous Protected Area	Deen Maar.
Marine National Park	Bunurong, Cape Howe, Churchill Island, Corner Inlet, French Island, Point Addis, Point Hicks, Port Phillip Heads, Twelve Apostles, Wilsons Promontory, Yaringa.
Marine Sanctuary	Barwon Bluff, Eagle Rock, Marengo Reefs, Merri, Mushroom Reef, Point Danger, The Arches.
Natural Catchment Area	Double Creek, East Gippsland Coastal streams, Mount Vereker Creek.
Nature Conservation Reserve	Bats Ridge W.R., Breamlea F.F.R., Johnstones Creek F.R., Marengo N.C.R., Narrawong, F.R., Nelson SS.R., Salt Lagoon, St Leonards W.R., Seal Islands W.R., Swan Bay – Edwards Point W.R., Tarwin Lower F.R., Tyrendarra F.R., Yambuk F.F.R., Yanakie F.R..
Natural Features Reserve	Aire River W.R., Aireys Inlet B.R., Anglesea B.R., Bald Hills B.R., Barham Paradise S.R., Bass River SS.R., Bellarine I109 B.R., Bellarine I110 B.R., Bittern B.R., Bolwarra H43 B.R., Bolwarra H44 B.R., Bolwarra H45 B.R., Buckley N.C.R., Cape Patterson N.C.R., Conewarre K47 SS.R., Conewarre K48 SS.R., Corinella Cemetery B.R., Crib Point G228 B.R., Crib Point G229 B.R., Curdie Vale N.C.R., Devilbend N.F.R., Drakes B.R., Dromana B.R., Drumdlemara H1 B.R., Drumdlemara H2 B.R., Drumdlemara H4 B.R., Edna Bowman N.C.R., Fingal B.R., Flinders G234 B.R., Flinders N.F.R., French Island G230 B.R., Goose Lagoon W.R., Gorae B.R., Grantville N.C.R., Hedditch Hill S.R., Hopkins Falls S.R., Johanna Falls S.R., Kangerong N.C.R., Kentbruck H14 B.R., Kentbruck H50 B.R., Kilcunda N.C.R., Lady Julia Percy Island W.R., Lake Aringa W.R., Lake Connewarre W.R., Lake Gillear W.R., Latrobe B.R., Lawrence Rocks W.R., Leongatha H3 B.R., Lily Pond B.R., Lonsdale Lakes W.R., Main Ridge N.C.R., Mallacoota, B.R., Merricks Creek B.R., Mortimers Paddock B.R., Mouzie B.R., Mouzie N.F.R., North Western Port N.C.R., Olivers Creek B.R., Portland H46 B.R., Portland H47 B.R., Princetown W.R., Queenscliff N.F.R., Reef Island and Bass River Mouth N.C.R., Rosebud B.R., Screw Creek N.C.R., Tower Hill W.R., Trewalla H48 B.R., Trewalla H49 B.R., Ventnor B.R., Waratah B.R., Warrengine Creek SS.R., Wild Dog B.R., Wild Dog Creek SS.R., Wongarra B.R., Wonthaggi G237 B.R., Wonthaggi G238 B.R., Wonthaggi G239 B.R., Wonthaggi G240 B.R., Wonthaggi G241 B.R., Wonthaggi Heathlands N.C.R., Yambuk Wetlands N.C.R.
National Park	Croajingolong, French Island, Great Otway, Lower Glenelg, Mornington Peninsula, Mount Richmond, Ninety Mile Beach, Point Nepean, Port Campbell, Wilsons Promontory.
National Parks Act Schedule 4 park or reserve	Bunurong Marine Park, Corner Inlet Marine and Coastal Park, Nooramunga Marine and Coastal Park, Shallow Inlet Marine and Coastal Park, Wilsons Promontory Marine Park, Wilsons Promontory Marine Reserve.
Private Nature Reserve	Unnamed C0293, Unnamed P0176.
Other	Phillip Island Nature Park.
Reference Area	Anser Island, Baawang, Benedore River, Calder River, French Island (north), Painkalac Creek, Parker River, Seal Creek, Sony Creek (Otway), Vereker Creek.

Area Type	Protected Area
Remote and Natural Area – Schedule 6 National Parks Act	Rame Head, Southern Wilsons Promontory, Wilsons Promontory Islands.
State Park	Arthurs Seat, Cape Nelson.
State Reserve	Lavinia.
Wilderness Zone	Cape Howe, Sandpatch, Wilsons Promontory.
SA State Protected Areas	
Conservation Park	Carpenter Rocks, Dingley Dell, Douglas Point, Ewens Ponds, Lower Glengelg Rier, Nene Valley, Piccaninnie Ponds.
Forest Reserve	Dry Creek.
Game Reserve	Bucks Lake.
Heritage Agreement	Unnamed No HA1038, Unnamed No HA1166, Unnamed No HA1180, Unnamed No HA1404, Unnamed No HA1457, Unnamed No HA1560, Unnamed No HA26, Unnamed No HA42, Unnamed No HA497.
Marine Park	Lower South East, Upper South East.
National Park	Canunda.
TAS State Protected Areas	
Conservation Area	Arthur Bay, Arthur-Pieman, Blyth Point, Brick Islands, Brougham Sugarloaf, Bun Beetons Point, Cape Wickham, Catamaran River, Cataraqui Point, Chalky Island, City of Melbourne Bay,, Colliers Swamp, Cone Islet, Counsel Hill, Craggy Island, Deep Lagoons, East Moncoeur Island, Egg Beach, Eldorado, Gentle Annie, Goose Island, Harbour Islets, Harcus Island, Henderson Islets, Hogan Group, Hunter Island, Jacksons Cove, Kangaroo Island, Kentford Forest, Kings Run #2, Little Chalky Island, Little Island, Little Trefoil, Low Point, Marshall Beach, Mile Island, Mount Bruny, Mulligans Hill, Murkay Islets, Nares Rocks, Ocean Beach, Pasco Group, Porky Beach, Prime Seal Island, Rebecca Creek, Red Hut Point, Reef Island, Roydon Island, Seacrow Islet, Sea Elephant, Seal Rocks, Sentinel Island, Settlement Point, Shell Islets, Sister Islands, Slaves Bay, Southport Lagoon, Southwest, Stokes Point, Sugarloaf Rock, Tathams Lagoon, Tully River, Wallaby Islands, Wybalenna Island.
Conservation Covenant	Colliers Forest Reserve, Harcus River Road Marrawah, Kentford Road, King Island, Leprena Trust – Sullivan Point, Loorana, Lymwood, Marrawah #1 and #3, Memana, Millwood Road, Mulligans Hill, Nugara, Pegarah Forest, Recherche Bay Reserve – Southport Lagoon, Red Hut Road #1, Reekara Road #1 and #2, Sandfly Beach, Sea Elephant Bootlace, Sea Elephant River, Tambar, Temma, Wicks Road Nugara, Yambacoona.
Game Reserve	Actaeon Island, Bird Island, New Year Island, Petrel Islands, Stack Island.
Historic Site	Cape Sorell, Currie Lightkeepers Residence, D'Entrecasteaux Watering Place, Macquarie Harbour, Strahan Customs House.
Indigenous Protected Area	Badger Island, Preminghana.
Marine Conservation Area	Hippolyte Rocks.
Nature Reserve	Albatross Island, Badger Box Creek, Bass Pyramid, Big Green Island, Black Pyramid Rock, Chappell Islands, Christmas Island, Councillor Island, Curtis Island, Devils Tower, East Kangaroo Island, Isabella Island, Kentford Forest, Lily Lagoon, Muddy Lagoon, North East Islet, Penguin Islet, Reid Rocks, Rodondo Island, The Doughboys, West Moncoeur Island, Wright Rock.
Nature Recreation Area	Emita, Killiecrankie, Mount Tanner, Palana Beach, Recherche Bay.
National Park	Kent Group, South Bruny, Southwest, Tasman.
Private Nature Reserve	Kings Run, Pegarah.
Regional Reserve	Badger River, Four Mile Beach, Mount Dundas, Mount Heemskirk, Teepookana, Tikkawoppa Plateau, Warra Creek, West Coast Range.

Area Type	Protected Area
State Reserve	Calm Bay, Cape Wickham, Disappointment Bay, Pieman River, Seal Rocks, Sundown Point, Three Hummock Island, Trial Harbour, Welcome River, West Point.
NSW State Protected Areas	
National Park	Ben Boyd.
Nature Reserve	Nadgee.

4.4.3 Key Ecological Features

KEFs are the parts of the marine ecosystem that are considered to be of importance for a marine region's biodiversity or ecosystem function and integrity (DoEE, n.d.c). KEFs have been identified by the Australian Government on the basis of advice from technical experts regarding the ecological processes and characteristics of the area.

The OA overlaps with one KEF, the West Tasmania Canyon KEF. In addition to the West Tasmania Canyon KEF, the EMBA overlaps with the following additional KEFs:

- Bonney Coast Upwelling;
- Big Horseshoe Canyon;
- Canyons on the Eastern Continental Slope;
- Seamounts South and East of TAS; and
- Upwelling East of Eden.

A summary of the relevant KEFs within the OA and EMBA is described in **Section 4.4.3.1** to **4.4.3.6** and reflected in **Figure 14**. Unless otherwise stated, all information describing the KEFs of the OA and EMBA has been taken from the Department of Climate Change, Energy, the Environment and Water (**DoCCEEW**) SPRAT Database.

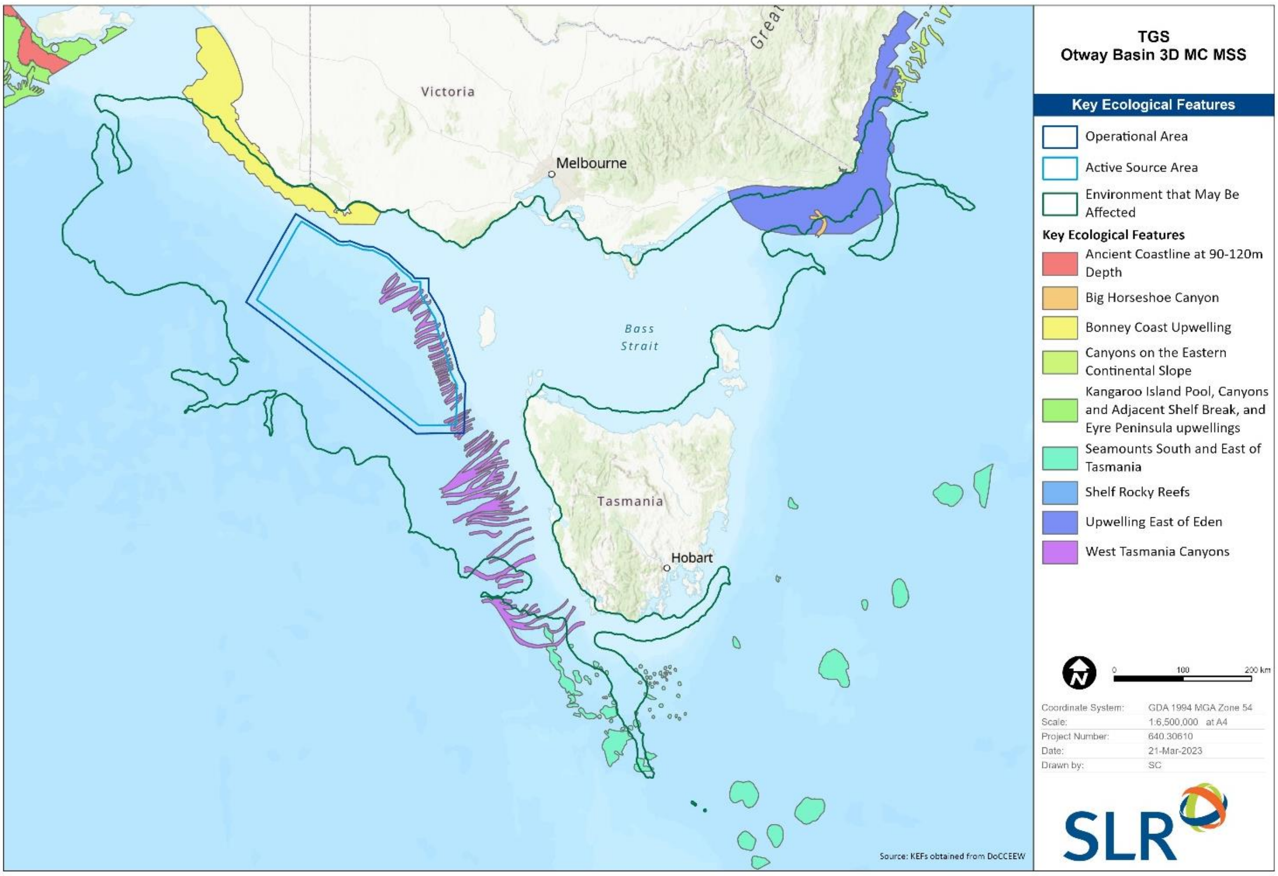

Figure 14 KEFs Identified within the OA, EMBA and Surrounding Waters

4.4.3.1 West Tasmania Canyons KEF

The West Tasmania Canyons KEF is located along the shelf margin, northwest of TAS. The topography and bathymetry of this KEF support a high biodiversity of benthic invertebrates and facilitate high productivity. This KEF overlaps with the boundaries of the OA and EMBA.

The canyons can influence ocean currents, facilitating upwellings that act as a source of nutrients around the canyon heads, and as a sink for rich organic sediments (Commonwealth of Australia, 2015). This results in higher productivity and biodiversity than surrounding waters. The canyon heads are associated with a high cover of sponges and bryozoans, with the greatest diversity between 200 m and 350 m depth (Schlacher *et al.,* 2010). Canyons to the south-east are characterised by bryozoan thickets along canyon rims and heads at 130 m to 350 m depth (Williams *et al*., 2009). Mobile epifauna (e.g. decapods) are found at rock terraces within the canyons at 300 m to 500 m depth, and bioturbating infauna found below 500 m in muddy sediments (Williams *et al*., 2009).

4.4.3.2 Bonney Coast Upwelling KEF

The Bonney Coast Upwelling KEF overlaps with the boundary of the EMBA and lies 12.8 km north of the closest boundary of the OA.

Upwelling events in southern Australian waters occur when seasonal south-easterly winds blow parallel to the shoreline, moving coastal waters offshore primarily between November and March. Cold nutrient-rich waters rise from depths exceeding 3,000 m to the surface via a series of submarine canyons, replacing the displaced coastal waters. Due to the orientation of the southern shelf, areas such as Eyre Peninsula, Kangaroo Island, the Bonney Coast (Robe to Portland) and eastern VIC are susceptible south-easterly winds that encourage upwelling events (Butler *et al*., 2002). The Bonney Coast upwelling is the most prominent of these upwelling systems and occurs along the coast of SA and VIC in areas where the continental slope is very close (~20 km) to shore. Large predictable seasonal upwelling plumes are regularly observed within this region (Schahinger, 1987).

The Bonney Coast Upwelling region supports high productivity and high species diversity in comparison to the surrounding southern Australian waters. A chain effect occurs whereby the cold nutrient rich waters of the upwelling result in increased phytoplankton abundance (represented by high levels of chlorophyll-α); in turn, this attracts zooplankton such as krill (*Nyctiphanes australis*) which feeds on the phytoplankton. Consequently, higher organisms such as fish, seabirds, little penguins (Collins *et al*., 1999), Australian fur seals and blue whales (*Balaenoptera musculus*) are attracted to the area. Other attributes of the area linked to the Bonney Coast Upwelling include its unique algal diversity (Womersley, 1984) and its productivity as a fishery.

The krill species *N. australis* forms swarm aggregations in surface waters, predominantly during summer months in response to increased productivity around the Bonney Coast Upwelling. These aggregations attract feeding blue whales, particularly on the continental shelf between Port Campbell, VIC, and Robe, SA – i.e the Bonney Coast – from December to April/May (Gill, 2001; 2002).

The relationship between the Bonney Upwelling and blue whales' presence has resulted in the Bonney Upwelling being listed as one of the 11 unique marine areas in Commonwealth waters. Furthermore, the Bonney Upwelling is one of 12 widely recognised and well-known blue whale feeding sites worldwide where the whales are known to frequent and feed in relatively high numbers. The Bonney Coast is also recognised as a feeding ground of an endangered species under the EPBC Act. Some authors have indicated that the Bonney Upwelling may be a possible blue whale breeding area although this is not widely agreed upon.

Butler *et al.* (2002) notes that 78 species occurring in the Bonney Upwelling area are covered by one or more of the provisions of the EPBC Act. *'….. Of these, 8 species (5 whales, 2 sharks and 1 bony fish) are not listed marine species but they are listed threatened species under the EPBC Act. The Bonney Upwelling area harbours, in total, 26 listed threatened species: one shark is listed as critically endangered; 5 birds and 2 whales are listed as endangered; and 11 birds, 1 shark, 3 whales and 1 bony fish are listed as vulnerable. The listed marine migratory species include 18 birds and 3 whales*.' Descriptions of several the threatened species associated with the Bonney Upwelling have been provided throughout **Section 4.5**.

4.4.3.3 Big Horseshoe Canyon

The Big Horseshoe Canyon KEF lies south of the coast of eastern VIC and is the eastern most arm of the Bass Canyon system. The KEF lies 554 km east of the OA.

Big Horseshoe Canyon is an area of high productivity and aggregations of marine life. The steep, rocky slopes of this KEF provide hard substrate habitat for large, attached megafauna and sponges and other habitat forming species provide structural refuge for benthic fish such as pink ling. This KEF is the only known temperate location of the stalked crinoid *Metacrinus cyaneu*, which occurs at depths of 200 – 300 m.

4.4.3.4 Canyons on the Eastern Continental Slope

The Canyons on the Eastern Continental Slope KEF lies along the north-eastern most boundary of the EMBA and is an area of high productivity and aggregations of marine life. The KEF lies 724 km northeast of the OA.

This KEF is identified as a unique seafloor feature that contributes to the overall habitat diversity of the seafloor by providing hard surfaces in depth zones where soft sediment habitats prevail. Large benthic sponges and feather stars are abundant, with particularly high diversity found in the upper slope regions (150 – 700 m).

4.4.3.5 Seamounts South and East of Tasmania

The Seamounts South and East of Tasmania KEF overlaps with EMBA south of TAS and is an area of high productivity and aggregations of marine life. The KEF lies 305 km southeast of the OA.

The seamounts within this KEF form a chain of seamounts that rise from the abyssal plain, continental rise, of plateau 200 km or more from shore. These seamounts influence and intensify the surrounding currents where they create localised upwellings and turbulent mixing.

The seamounts with their hard substrate summits and slopes provide attachment points for sessile invertebrates, while soft sediments on the seamounts provide habitat for burrowing species.

4.4.3.6 Upwelling East of Eden

The Upwelling East of Eden KEF overlaps with the EMBA in the north-east and is an area of high productivity and aggregations of marine life. The KEF lies 460 km northeast of the OA.

Dynamic eddies of the EAC cause episodic productivity events within the KEF when they interact with the continental shelf and headlands. This mixing and nutrient enrichment events drive phytoplankton blooms that form the basis of productive food chains. These upwelling events support regionally high primary productivity which in turn supports fisheries and biodiversity. The KEF is one of two feeding areas for blue whales and humpback whales, known to arrive when significant krill aggregations have formed. Other cetaceans, seals, sharks, and seabirds also rely on the KEF.

4.4.4 Biologically Important Areas

Biologically Important Areas (**BIA**s) are regions where a particular species is known or likely to display important behaviours such as breeding, foraging, nesting or migration (DoEE, n.d.c). Whilst BIAs are not matters of national environmental significance and have no legal status, they provide useful biological information intended to help inform regulatory and management decisions under the EPBC Act.

Based on the results contained within the EPBC Act Protected Matters Report, 34 threatened or migratory species were identified as having a BIA that overlaps with either the OA and/or the EMBA. A summary of the relevant BIAs and locational information is provided **Table 16**. Further information on these BIAs is provided in the individual species descriptions in **Section 4.5.3** to **Section 4.5.7**, where relevant.

Table 16 Marine Threatened and Migratory Species BIAs within the OA and EMBA

Class	Species	BIA activity	Closest Location of BIAs	Distance of closest BIA from OA (km)
Elasmobranchs	Grey nurse shark	Foraging	Off the coast of Eden	650 km NE of OA
		Migration (2 BIAs)	Off the coast of Eden	663 km NE of OA
	White shark	Breeding (nursery area)	Corner Inlet	285 km E of OA
		Distribution (2 BIAs)	Between the 60 – 120 m depth contour	Both overlap OA
		Distribution (low density)	Australian waters from Barrow Island/Montebello Islands, Western Australia to Yeppoon/Swains Reef QLD	Overlaps OA
		Foraging	Waters off pinniped colonies throughout the SEMR and SWMR	15 km N of OA
		Known distribution	Coastal/shelf/upper slope waters out to 1,000 m depth contour	Overlaps OA
Marine mammals	Pygmy blue whale	Distribution	N/A[3]	Overlaps OA
		Foraging	The majority of Bass Strait and the coastal waters of Tasmania	Overlaps OA
		Foraging (abundant food source)	Eastern GAB upwelling (Kangaroo Island Canyons)	268 km NW of OA
		Foraging (annual high use area)	Between Cape Otway and Robe. The Bonney Upwelling is a well described pygmy blue whale feeding area	Overlaps OA
		Known foraging area (2 BIAs)	The north-west part of Bass Strait, from Cape Otway to Port Phillip Heads and to the south of King Island	Overlaps OA
	Southern right whale	Aggregation	Bridgewater Bay, Portland to E of Logan's Beach, Warrnambool	14 km N of OA
		Breeding likely	SE Tasmania	381 km SE of OA

[3] No location data provided in BIA files, however, this BIA includes waters offshore from Western Australia around to the VIC/NSW border, including TAS.

Class	Species	BIA activity	Closest Location of BIAs	Distance of closest BIA from OA (km)
		Connecting habitat (3 BIAs)	King Island area	37 km E of OA
		Known core range	Southern Right Whales occur in coastal waters anywhere between Sydney and Perth, including off Tasmania	Overlaps OA
		Migration and resting on migration (6 BIAs)	Victor Harbour area to Portland	32 km N of OA
	Humpback whale	Foraging	From NSW-QLD border to Eden	640 km NE of OA
	Sperm whale	Foraging likely (abundant food source)	Kangaroo Island canyons (south)	326 km NW of OA
	Australian sea lion	Foraging (male)	Great Australian Bight, Eyre Peninsula, Spencer Gulf, Investigator Passage, Gulf of St Vincent and Kangaroo Island	97 km NW of OA
		Foraging (male and female)	Kangaroo Island, Investigator Passage and Gulf of St Vincent	312 km NW of OA
Marine Birds	Wedge-tailed shearwater	Foraging (2 BIAs)	Breeding area / sites buffer-Muttonbird Island (VIC)	Overlaps OA
		Breeding	Montague Island, Muttonbird Island, Broughton Island - Muttonbird Island (VIC)	65 km N of OA
	Short-tailed shearwater	Foraging (3 BIAs)	Buffer around Tasmania including Bass Strait	Overlaps OA
		Breeding (89 BIAs)	Catarqui Point	40 km E of OA
	Wandering albatross	Foraging (2 BIAs)	The whole South-east Marine Region	Overlaps OA
	Antipodean albatross	Foraging (2 BIAs)	The whole South-east Marine Region including Macquaire Island	Overlaps OA
	Australasian gannet	Foraging (4 BIAs)	Buffer around the coast off Portland Vic	Overlaps OA
		Aggregation (7 BIAs)	Lawrence Rocks	39 km N of OA
	White-faced storm-petrel	Foraging (3 BIAs)	Buffer around the northern side of Tasmania into Bass Strait	Overlaps OA
		Breeding (12 BIAs)	Penguin Islet	99 km E of OA
	Common diving-petrel	Foraging	Buffer around Tasmania and Victoria	Overlaps OA
		Breeding (16 BIAs)	Lady Julia Percy Island	45 km N of OA
	Bullers albatross	Foraging	Most of the South-east Marine Region	Overlaps OA
	Shy albatross	Breeding	Albatross Island	89 km E of OA

Class	Species	BIA activity	Closest Location of BIAs	Distance of closest BIA from OA (km)
		Foraging likely	The whole South-east Marine Region	Overlaps OA
	Indian yellow-nosed albatross	Foraging (2 BIAs)	Most of the South-east Marine Region	Overlaps OA
		Foraging likely	The southern edge of the South-east Marine Region	495 km SE of OA
	Black-browed albatross	Foraging (2 BIAs)	The whole South-east Marine Region	Overlaps OA
	Campbell albatross	Foraging (2 BIAs)	The whole South-east Marine Region	Overlaps OA
	Flesh-footed shearwater	Foraging	Region based on Thalman paper	713 km NE of OA
	Sooty shearwater	Breeding (2 BIAs)	Maatsuyker Island	342 km SE of OA
		Foraging (3 BIAs)	Buffer around the south of Tasmania	240 km SE of OA
	Little penguin	Breeding (39 BIAs)	Christmas Island	50 km E of OA
		Foraging (17 BIAs)	Buffer around Christmas Island Tasmania	44 km E of OA
	Southern giant petrel	Foraging	Shelf region NSW coast	716 km NE of OA
	Northern giant petrel	Foraging	Shelf region NSW coast	716 km NE of OA
	Wilsons storm petrel	Migration	Shelf region NSW coast	716 km NE of OA
	Black-faced cormorant	Breeding (16 BIAs)	Christmas Island	50 km E of OA
		Foraging (10 BIAs)	Buffer around Christmas Island Tasmania	44 km E of OA
	Black petrel	Foraging	From Fraser Island to the southern coast of NSW out to and including the area around Lord Howe Island	716 km NE of OA
	Great-winged petrel	Foraging	South-east Queensland and NSW	716 km NE of OA
	Soft-plumaged petrel	Foraging	Buffer around the south of Tasmania	80 km SE of OA
		Breeding	Maatsuyker Island	342 km SE of OA
	White-fronted tern	Foraging	Cape Barren Island	368 km E of OA
	White-capped albatross	Foraging	Shelf region NSW coast, north from TEMR boundary to Sydney	716 km NE of OA
	Crested tern	Foraging	Montague Island	697 km NE of OA

4.4.5 The Australian Whale Sanctuary

The Australian Whale Sanctuary was established to protect all whales and dolphins in Australian waters, which are protected under the EPBC Act 1999. It includes all Commonwealth waters from the 3 NM State Waters limit out to the boundary of the Exclusive Economic Zone (**EEZ**). All States and Territories provide similar protection for cetaceans within Coastal Waters (up to 3NM), and it is the responsibility of the state and territory governments to protect whales and dolphins. Both the OA and EMBA overlap the Australian Whale Sanctuary.

Within the Sanctuary it is an offence to kill, injure or interfere with a cetacean. In all Australian waters, activities with the potential to significant impact on listed or migratory species, such as cetaceans, are regulated under the EPBC Act 1999 (see **Section 2.1.2**). Migratory species within the EPBC Act are those that are listed under international agreements as species whose protection requires or would significantly benefit from international cooperation. Any such proposed activity should therefore be referred to the Minister for the Environment and Heritage for assessment.

Australia is a signatory to the International Convention for the Regulation of Whaling. Obligations under this Convention include provision for the conservation of whales through the complete protection of select species, and the designation of whale sanctuaries (.

4.4.6 Ramsar Wetlands of International Importance

The Ramsar Convention on Wetlands is an intergovernmental treaty that aims to stop international wetland loss and to conserve those that remain. The Convention encourages member countries to nominate sites containing representative, rare or unique wetlands to the List of Wetlands of International Importance ('Ramsar sites'). Ramsar sites are recognised as a matter of national environmental significance under the EPBC Act (DoEE n.d.g). Due to its offshore location, there are no Ramsar sites within the OA, however, seven Ramsar sites occur within the EMBA (**Table 17**, **Figure 15**).

Table 17 Ramsar Wetlands of Relevance to the OA and EMBA

Ramsar Wetlands	Distance from OA
Glenelg Estuary and Discovery Bay Wetlands	37 km N of OA
Piccaninnie Ponds Karst Wetlands	47 km N of OA
The Coorong and Lakes Alexandrina and Albert Wetland	118 km N
Lavinia	63 km E of OA
Western Port	204 km NE of OA
Port Phillip Bay (Western Shoreline and Bellarine Peninsula)	168 km NE of OA
Corner Inlet	280 km NE of OA

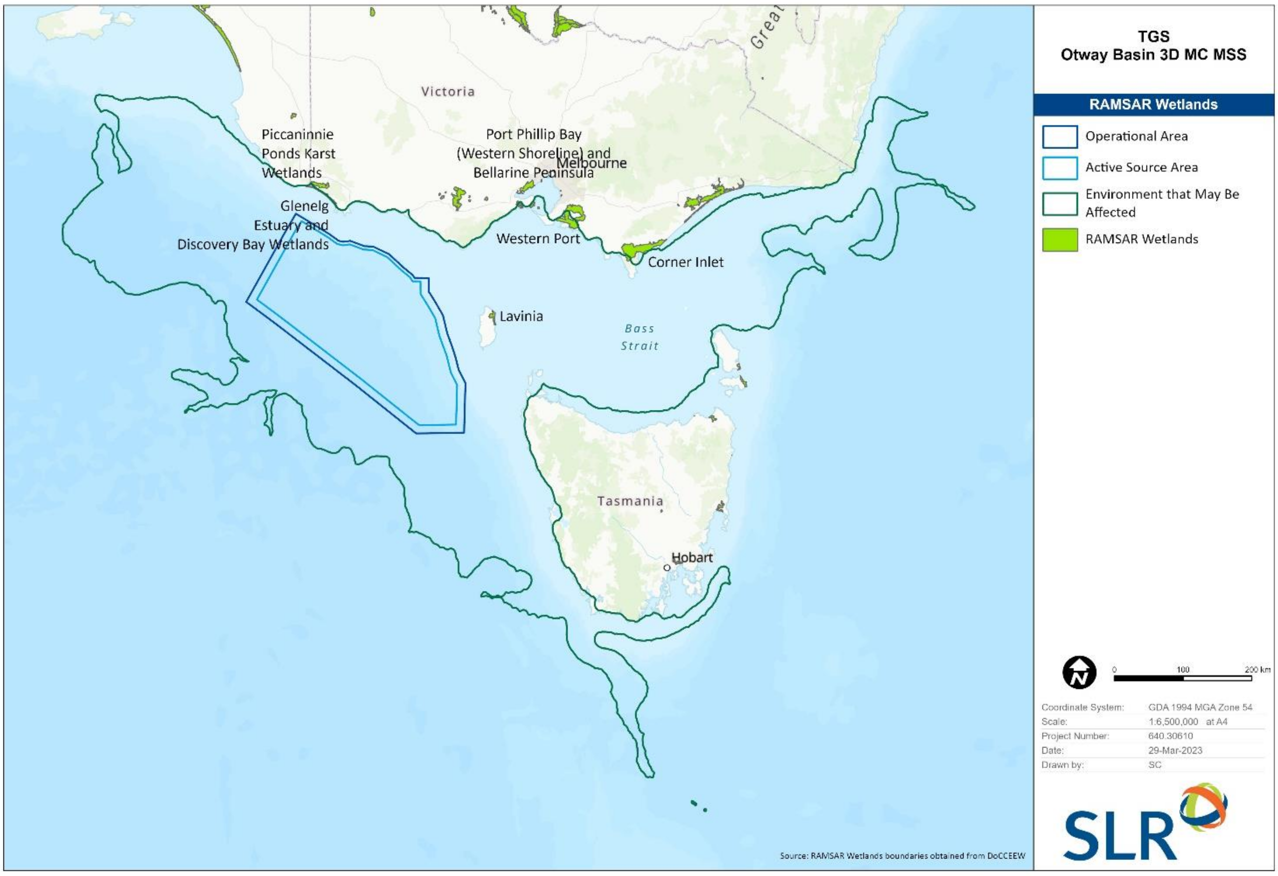

Figure 15 Ramsar Sites of Relevance to the OA and EMBA

4.4.7 Nationally Important Wetlands

Coastal wetlands typically form in the lower reaches of river valleys where they meet estuarine habitat, sometimes forming elongated lakes parallel to the coast and separated from the ocean by dunes. Therefore, water is often brackish in the seaward extents, influenced by the tide and river flows. Some are seasonal, but all provide habitat for numerous species of flora and fauna, particularly waterfowl.

There are no Nationally Important Wetlands located within the OA identified by the EPBC Act Protected Matters Report; however, 37 Nationally Important Wetlands have been identified within the EPBC Act Protected Matters Report as being present within the boundaries of the EMBA. These wetlands are listed in **Table 18** and depicted in **Figure 16**. Due to their distance from the OA, no Nationally Important Wetlands will be affected by routine activities carried out during the Otway Basin 3D MC MSS.

Table 18 Nationally Important Wetlands of Relevance to the EMBA

State	Nationally Important Wetland
VIC	Aire River, Anderson Inlet, Benedore River, Corner Inlet, Glenelg Estuary, Glenelg River, Lake Connewarre State Wildlife Reserve, Long Swamp, Lower Aire River Wetlands, Lower Merri River Wetlands, Mallacoota Inlet Wetlands, Mud Islands, Powlett River Mouth, Princetown Wetlands, Shallow Inlet Marine and Coastal Park, Swan Bay and Swan Island, Sydenham Inlet Wetlands, Tamboon Inlet Wetlands, Thurra River, Tower Hill, Western Port, Yambuk Wetlands.
TAS	Bungaree Lagoon, Lake Ashwood, Lake Bantick, Lake Flannigan, Lake Garcia, Lavinia Nature Reserve, Pearshape Lagoon 1 – 4, South East Cape Lakes, Unnamed Wetland.
South Australia	Ewens Ponds, Piccaninnie Ponds,
NSW	Nadgee Lake and tributary wetlands

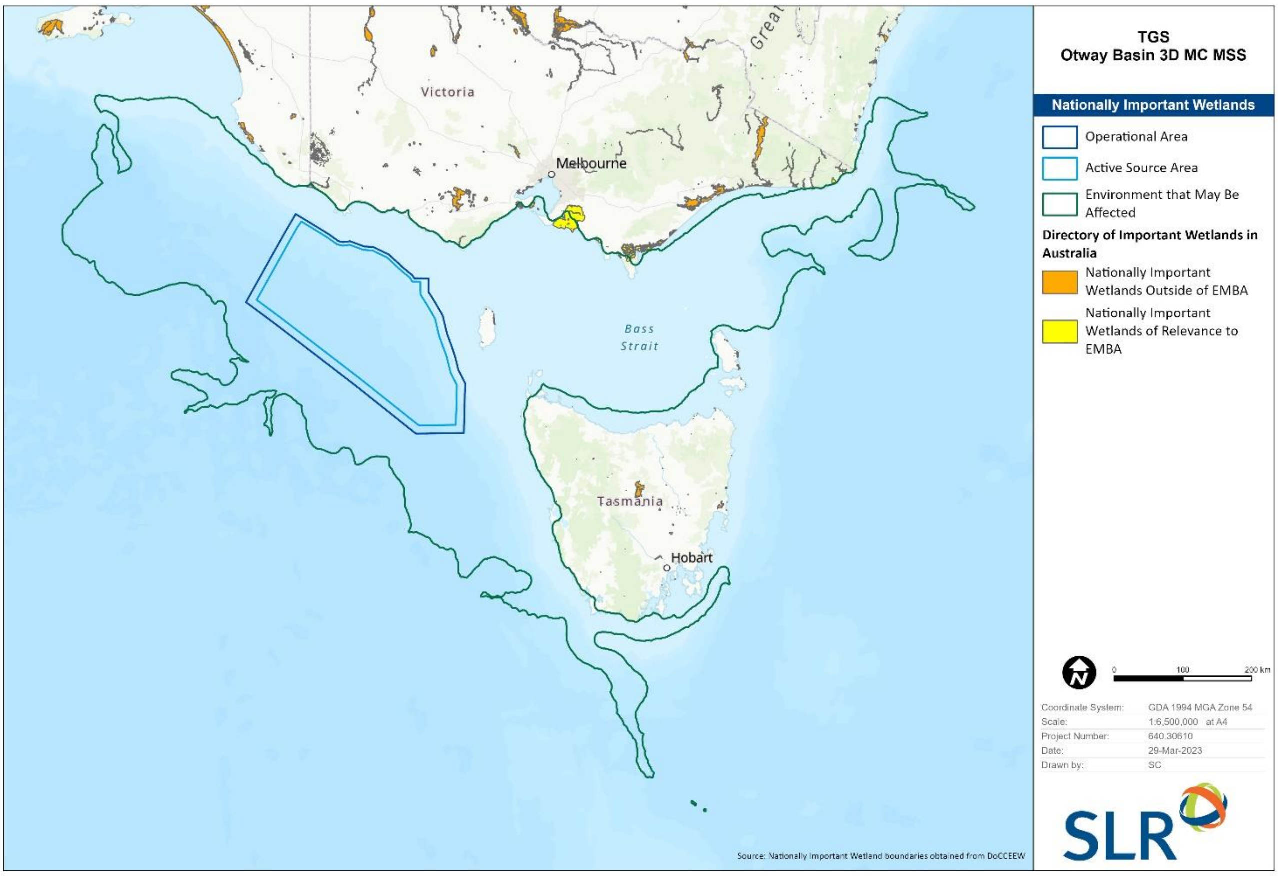

Figure 16 Nationally Important Wetlands of Relevance to the EMBA

4.4.8 State Protected Areas

4.4.9 World, Commonwealth and National Heritage Places

World heritage sites are natural or man-made sites, areas, or structures recognized as being of outstanding universal value by the United Nations Educational, Scientific and Cultural Organization (**UNESCO**). No listed World, Commonwealth or National Heritage places were identified within the OA. One World, six National, and 14 Commonwealth Heritage places were identified within the EMBA, these are identified in **Table 19**.

Table 19 World, Commonwealth and National Heritage Places of Relevance to the EMBA

Heritage Place	Distance from OA
World Heritage Properties	
Tasmanian Wilderness World Heritage Property	184 km SE
National Heritage Places (NHP)	
Quarantine Station and Surrounds	181 km NE
Western Tasmania Aboriginal Cultural Landscape National Heritage Place	81 km E
Point Nepean Defence Sites and Quarantine Station Area National Heritage Place	180 km NW
Recherche Bay (North East Peninsula) Area	369 km SE
Tasmanian Wilderness	188 km SE
Great Ocean Road and Scenic Environs National Heritage Place	57 km N
Commonwealth Heritage Places (CHP)	
Fort Queenscliff	182 km NE
Cape Sorell Lighthouse	165 km SE
Wilsons Promontory Lighthouse	283 km E
Gabo Island Lighthouse	631 km NE
Sorrento Post Office	184 km NE
HMAS Cerberus Central Area Group	215 km NE
Goose Island Lighthouse	355 km E
Tasman Island Lighthouse	423 km SE
Cape Wickham Lighthouse	63 km E
Swan Island and Naval Waters	185 km NE
Swan Island Defence Precinct	185 km NE
Tasmanian Seamounts Area	446 km SE
Cape Northumberland Lighthouse	39 km N
HMAS Cerberus Marine and Coastal Area Group	215 km NE

4.4.10 Threatened Ecological Communities

No TECs overlap with the OA. TECs in nearshore waters and intertidal areas in the EMBA (based on the results presented in the EPBC Act Protected Matters Report include:

- Assemblages of species associated with open-coast salt-wedge estuaries with open-coast salt-wedge estuaries of western and central Victoria ecological community;
- Giant Kelp Marine Forests of South East Australia; and
- Subtropical and Temperate Coastal Saltmarsh.

4.4.10.1 Assemblages of species associated with open-coast salt-wedge estuaries with open-coast salt-wedge estuaries of western and central Victoria ecological community

The Assemblages of species associated with open-coast-salt-wedge estuaries of western and central Victoria ecological community (herein referred to as 'the Assemblages TEC') are listed as Endangered under the EPBC Act.

The Assemblages TECs are in 25 different VIC locations, between the SA – VIC border and the most southerly point of Wilsons Promontory. The Assemblages TECs are in dynamic salt-wedge estuarine systems that experience high wave energy, a microtidal regime (< 2 m), and a temperate climate (TSSC, 2018). Salt-wedge estuaries are usually highly stratified, with saline bottom waters forming a 'saltwedge' below the inflowing freshwater layer of riverine waters. The wedge of heavier marine waters is introduced into the estuary by wave energy and tides. The dynamic nature of salt-wedge estuaries has important implications for the biological structure and ecological function of the Assemblages TEC.

The composition of flora and fauna varies between each of the Assemblages TECs. Primary producers include macrophytes, phytoplankton and protists that live in the water-column, on substrates, or submerged (or intermittently submerged) riparian vegetation along the estuary margins. Beds of seagrass (*Zostera muelleri*, *Ruppia* spp., and *Heterozostera tasmanica*) may occur in the lower to mid reaches of the Assemblage TEC. Fringing wetlands and riparian vegetation adjacent to the main channel may occur and, although not part of the ecological community, are included in this TEC's associated buffer zones.

The faunal composition of the Assemblages TEC comprises many invertebrates: copepods, ostracods, crabs, polychaetes, nematodes, sea jellies and bivalve molluscs. Vertebrates that inhabit the Assemblages TEC include the estuarine black bream and estuary perch.

4.4.10.2 Giant Kelp Marine Forests of South East Australia

The Giant Kelp Marine Forests of South East Australia TEC has been progressively lost, especially on the east coast of TAS, due to changing oceanographic conditions. The largest extent of the ecological community is in TAS coastal waters, with some patches also found in VIC and SA. These patches are protected under Australia's national environmental law, the EPBC Act as a TEC (TSSC 2012a).

Giant kelp is the largest and fastest growing marine plant, and the foundation of the Giant Kelp Marine Forests of South Australia TEC. Other components of the TEC include a large range of marine algae, reef associated fish and numerous invertebrates that shelter, feed, and reproduce within giant kelp marine forests (TSSC 2012a).

4.4.10.3 Subtropical and Temperate Coastal Saltmarsh

This TEC spans six State jurisdictions: Queensland (southern), NSW, TAS, SA, Western Australia (south-western) and VIC. This TEC is found in coastal areas under regular or intermittent tidal influence and is typically restricted to upper intertidal areas with soft sediments generally consist of poorly sorted anoxic sandy silts and clay. The drainage characteristics of coastal soils, along with tidal patterns and elevation, can strongly influence the distribution of flora and fauna within the TEC (TSSC, 2013a).

Although the TEC is found in several Australian regions, it shows geographical zonation between the eastern, southern, and western subgroupings. This means that the species composition of the TEC varies across Australia. In general, the TEC is dominated by salt-tolerant herbs, shrubs, grasses, sedges, and rushes. The non-vascular primary producers in the TEC include epiphytic algae, diatoms, and cyanobacterial mats. The VIC patches of this TEC are dominated by succulent shrubs of the genera *Tecticornia* and *Sarcocornia* in the lower saltmarsh zone, and herbs and grasses in the landward, upper-intertidal zones.

A high diversity of infaunal and epifaunal invertebrates are associated with this TEC. The dominant marine invertebrates are crabs of the families Grapsidae and Ocypodidae. Molluscs are also common in the TEC, and include bivalves, sea slugs of the family Onchidiidae, and several families of gastropods. Shrimp and prawns can swim against currents and are regular, transient visitors to the TEC when it is linked to adjacent aquatic habitats at high tide.

Several vertebrate groups transient fish assemblages are found in the TEC when it is inundated at high tide. These fish are typically adult glassfish (Ambassidae), hardyheads (Atherinidae), or gobies (Gobiidae). The TEC provides important feeding, roosting and refuge habitat for resident and migratory shorebirds (including colonial water birds), as well as foraging habitat for insectivorous bats, terrestrial birds of prey, and seed-eating and insectivorous birds.

4.5 Biological Environment

4.5.1 Plankton and Primary Producers

The term ‘plankton’ describes the drifting organisms that inhabit aquatic environments. Plankton travel with the ocean currents and although some plankton can move vertically within the water column, their horizontal distribution is primarily determined by the surrounding currents. This assessment considers two broad functional planktonic groups:

- Phytoplankton – free-floating organisms ranging from 0.2 to 200 mm in size, capable of photosynthesis, which includes diatoms and dinoflagellates. Phytoplankton fulfil the primary producer role in the ocean and form the basis of the marine food web; and
- Zooplankton – free-floating animals which includes copepods, jellyfish, and larval stages of larger animals.

Primary production within the SEMR is enhanced by broad oceanographic influences (Hosack and Dambacher, 2012):

- The mixing of surface waters with nutrient rich sub-Antarctic waters, leading to high chlorophyll concentrations in the north-eastern Bass Strait; and
- Autumnal and spring bloom of primary productivity observed on the East Tasmania Subtropical Convergence Zone.

These areas of high pelagic productivity support top predators, such as marine mammals, pinnipeds, and seabirds, as well as key commercial fisheries. Interannual variability in the productivity of the Subtropical Convergence Zone has been linked to changes in associated fisheries, as fish may time spawning events, so larvae develop during increased primary production events (Hallegraeff and Jeffrey, 1993; Young *et al*.,1993).

There is limited understanding on the community composition of plankton within the Otway Basin, however, it is thought to be like those found within the Bass Strait and GAB due to geographic proximity and environmental conditions. The eastern GAB has reported seasonal variability in zooplankton community composition. Typically, copepods and cladocerans are dominant members year-round, with elevated chlorophyll-a concentrations during summer/autumn upwellings having a positive association with zooplankton with opportunistic reproductive stages (van Ruth and Ward ,2009).

The planktonic communities of the Bass Strait are influenced by several key upwellings and water flows through the region including the Bass Cascade, East Eden upwelling and the East Australian Current. Whilst copepods are a primary member of these assemblages, ichthyoplankton account for a large proportion of plankton throughout the region, particularly in shallower nutrient rich waters, forming the foundation of several commercial fisheries (Kent *et al*., 2013). It is likely the Otway Basin will display similar plankton assemblages to both the GAB and Bass Strait communities, with influences from temporal and seasonal variations in environmental conditions within the region.

Within the OA, plankton distribution is dependent upon water movement from the Bass Strait and Southern Ocean, as well as localised prevailing currents such as the Leeuwin, Flinders and Zeehan (**Section 4.3.3**) (CoA, 2015). Two key features within the OA promote areas of high productivity:

- The Bonney Upwelling (**Section 4.4.3.2**). A seasonal wind driven coastal upwelling brings cooler nutrient rich water which create areas of high primary production. Significantly, this includes swarms of the coastal krill *Nyctiphanes australis*, the principal *euphausiid* in the area (Hosack and Dambacher, 2012). Surface swarms of coastal krill are predominately a summer phenomenon; however, they have been reported in winter on occasion. These swarms are a key contributing factor to the aggregation of blue whales in the SEMR; and
- The West Tasmania Canyons (**Section 4.4.3.1**). The bathymetry of this KEF has a localised influence on currents, with cold nutrient rich upwelling at canyon heads creating productivity and biodiversity hotspots.

4.5.2 Benthic Habitats and Communities

The distribution of benthic communities in the SEMR is largely dependent on water depth, nutrient availability, and substrate and sediment characteristics. Due to the OA having a large depth range down to approximately 5,000 m, a range of different habitat/substrate types, and consequently benthic communities will be present. The seabed of the shelf edge and slope (180 m - >500 m) is expected to consist of muddy carbonate sands and rocky reefs, which disappear with depth (Williams *et al*., 2009). The shelf edge is intersected by canyons and gullies consisting of unconsolidated sediments. The hard substrates and rocky reliefs provide attachment points for a broad range of sessile epifauna, whereas infauna can be found within the sediments.

Information on benthic invertebrate communities within the OA is limited. However, the likely benthic invertebrate communities within the OA are based on studies for nearby areas. The southern Australian waters are reported as having a variety of seabed habitats, supporting diverse infaunal and epifaunal communities, which display little evidence of any distinct biogeographic regions (Poore *et al.,* 1985; Wilson and Poore, 1987).

The Continental Shelf is likely to be sparsely covered by macroalgae, sessile filter feeders (e.g. sponges, bryozoans, bivalves, scallops, stalk crinoids, soft corals), mobile macro-invertebrates (e.g. echinoderms, crustacean) and bioturbating infauna (e.g. annelids) (Hosack and Dambacher, 2012; Williams *et al.,* 2009). Studies by the Museum of Victoria found high invertebrate diversity across the SEMR, but patchy distribution and little evidence of distinct biogeographic regions (Butler *et al.*, 2001). Whilst hard corals are generally associated with tropical waters, some habitats conducive to deep-water corals can be found within the SEMR, as well as two reports of octocorals along the Continental Shelf. Deepwater corals are generally limited to water depths of less than 1,000 m and unlikely to be a dominant habitat throughout the SEMR (VEAC, 2019). Several areas that overlap the OA support a high diversity of benthic assemblages, namely the Apollo and Zeehan AMPs (**Section 4.4.1**) and West Tasmania Canyons KEF (**Section 4.4.3.1**).

One species of threatened seastar, the Tasmanian live-bearing seastar (*Parvulastra vivipara*), was identified within the EPBC Act Protected Matters Report as potentially present within the EMBA. This species is listed as Vulnerable under the EPBC Act 1999 and under the Tasmanian Threatened Species Protection Act 1995. Tasmanian live-bearing seastars inhabit sheltered waters in the upper intertidal zone of rocky areas of southeast TAS and therefore will not be affected by planned activities associated with the Otway Basin 3D MC MSS but is of relevance to an unplanned fuel oil spill.

4.5.3 Bony Fish and Elasmobranchs

The EPBC Act Protected Matters Report identified three species of threatened fish, three species of threatened shark, and two species of migratory shark within the OA. A further 20 species of pipefish, two species of seahorse, two species of seadragon, and two species of pipehorse have also been identified within the OA which are not listed as threatened or migratory. Within the EMBA there are 12 species of threatened fish and seven species of threatened elasmobranch (i.e sharks, rays, and skates) identified within the EPBC Act Protected Matters Report. An additional 4 migratory elasmobranch species and 36 species of not threatened or migratory fish (pipehorses, pipefish, seahorses, and seadragons) have been identified within the EMBA.

Threatened and migratory species are further described in **Section 4.5.3.1.1** (bony fish) and **Section 4.5.3.1.2** (elasmobranchs), with the full list of fish and elasmobranchs identified within the OA and EMBA provided in the EPBC Act Protected Matters Report (**Appendix D**).

4.5.3.1 Bony Fish

Temperate fish assemblages across the SEMR consist of pelagic, demersal, and nearshore species, with deepwater fishes the most relevant to the region. Habitats, such as rocky reefs and sponge gardens, provide refuge for herbivorous fish or important nursery grounds for commercially viable species (Butler *et al.*, 2002a). Reef dwelling fish include wrasse, leatherjacket, scalyfin, and bream, and are widely distributed though the TAS and south Australian coastline. Pelagic assemblages include several tuna species, marlin, lanternfish, mackerel, sardine and redbait (Bulman *et al.*, 2008). Demersal assemblages include orange roughy, deepwater flathead, whiting and grenadier, however, assemblages below 1,125 m are data deficient (CSIRO, 2001).

The sygnathids (pipefish, pipehorses, seahorses, and seadragons) identified in the EPBC Act Protected Matters Search occur broadly across the western, south-western, south-eastern and eastern Australian waters. It is likely the principal habitat that may support syngnathids within the OA is inner shelf areas of less than 50 m, including the Zeehan and Apollo Marine Parks, as well as within rocky reefs and floating kelp mats found across the SEMR. Benthic cover and rugosity of substrate is likely to be a key factor in determining site-attached fish habitats.

Other key areas of fish aggregation are localised upwellings, including the Bonney Upwelling and West Tasmania Canyons, where increased primary production is capitalised on by migratory species such as tuna and large sardine schools (Butler *et al.*, 2002b).

4.5.3.1.1 Bony Fish Listed Threatened Species

12 threatened fish species were identified within the EPBC Act Protected Matters Report as potentially occurring in the OA and/or the wider EMBA. A description of the threatened bony fish species identified in the EPBC Act Protected Matters Report is provided in **Table 20**. There are no bony fish species listed as migratory identified within the OA or EMBA.

Table 20 EPBC Act List of Threatened Bony Fish Species Identified within the OA and/or EMBA

Species	EPBC Act Status	Description of species and potential to occur within the OA and EMBA
Orange roughy *Hoplostethus atlanticus*	CD	Orange roughy are found in cold, deep waters of the Atlantic, Pacific and Indian Oceans. In Australia this species occurs across the southern half of the continent, from central NSW through to southwestern Australia, including TAS (Kailola *et al*., 1993). Orange roughy are a demersal species most found on the Continental Slope at 500 – 1,400 m depth (Gomon *et al*., 2008) where they often aggregate around seamounts such as the South Tasman Rise and Cascade Plateau in the SEMR (Kailola *et al*., 1993). The first major orange roughy spawning ground was discovered in 1989 off northeastern TAS and a summer fishing ground was discovered off southern TAS (Koslow *et al*., 1995). Catch data indicates that there has been a significant decline in orange roughy populations in Australia since the establishment of the commercial fishery in late 1980. Orange roughy are likely to be present within the OA during the Otway Basin 3D MC MSS. **Relevant management plan**: No adopted EPBC documented recovery plan for orange roughy. **Key threats**: The main threats to orange roughy are commercial trawling and habitat damage (mainly through bottom trawling over seamounts).
Blue warehou *Seriolella brama*	CD	Blue warehou are restricted to Australian and New Zealand waters (Kaschner *et al*., 2010). In Australia, this species occurs predominantly in coastal shelf, upper continental slope, and seamount waters offshore from NSW, TAS, VIC and South Australia (Gomon, 2008). Blue warehou inhabit water depths between 3 and 550 m (Bray and Gomon, 2011), but is more abundant in waters shallower than 200 m (Gavrilov and Markina, 1979). Blue warehou are managed by the Australian Fisheries Management Agency (**AFMA**) as two stocks: an eastern stock extending offshore from southern NSW southwards to southeastern TAS, and a western stock extending offshore from western TAS northwards to western VIC. Spawning occurs three times each year. The main spawning period in the eastern stock occurs between May and August each year, while in the western stock, spawning occurs between June and October each year (Knuckey and Sivakumaran, 2001). Post spawning, the larvae disperse widely during winter and spring months within shelf and slope waters (Bruce *et al*., 2001). Blue warehou are likely to be present within the OA during the Otway Basin 3D MC MSS. **Relevant management plan**: No adopted EPBC documented recovery plan for blue warehou, however, a Listing Advice is in effect from 14 February 2015. **Key threats**: The main threat to blue warehou is overfishing in the commercial fishery.
Southern bluefin tuna *Thunnus maccoyii*	CD	See **Section 4.5.3.1.2** for a full discussion on southern bluefin tuna. Based on the tracks of tagged adult southern bluefin tuna depicted in **Figure 20**, adults may be present in the OA from October to December (Patterson *et al*., 2015). **Relevant management plan:** No adopted EPBC documented recovery plan for southern bluefin tuna, however, a Listing Advice is in effect from 15 December 2010. **Key threats:** The main threat to southern bluefin tuna is historic and ongoing fishing pressure.

Species	EPBC Act Status	Description of species and potential to occur within the OA and EMBA
Spotted handfish *Brachionichthys hirsutus*	CE	Spotted handfish are a slow-moving benthic species endemic to south-east TAS. This species is currently known from the lower Derwent Estuary and D'Entrecasteaux Channel (Bruce *et al*., 1998) in small, fragmented populations (Last and Gledhill, 2009). They associate with coarse to fine sand and shell grit of stilt (DPIWE, 2002) at depths of 1 – 60 m, but most commonly in depths of 5 – 15 m (Last and Gledhill, 2009). Spotted handfish will not be present within the OA and will not be affected by routine planned activities during the Otway Basin 3D MC MSS, however, this species is of relevance with regard to unplanned activities associated with a fuel oil spill (**Section 8.3**). **Relevant management plan**: Recovery Plan for Three Handfish Species 2015. Objectives of the recovery plan are to ensure an ecologically functional wild population of spotted handfish that, with limited site-specific management, has a high likelihood of persistence in nature, and to increase the understanding of the biology and ecology of spotted handfish to conserve, and contributed to the future recovery of the species. **Key threats**: Key threats include loss/degradation of habitat, pollution, and siltation of waterways from diffuse and point-source activities, traditional boat moorings, and the spread of the invasive Northern Pacific seastar.
Ziebell's handfish *Brachiopsilus ziebelli*	V	Ziebell's handfish are a benthic species restricted in distribution to eastern and southern TAS in widely disjunct populations (Last and Gledhill, 2009). This species has been recorded at Bicheno, Forestier Peninsula, Tasman Peninsula, Actaeon Islands, and Cox Bight in water depths of 10 – 20 m (Last and Gledhill, 2009). Ziebell's handfish prefer soft bottomed habitat, with patches of rock that support sponge and algae communities. Ziebell's handfish will not be present within the OA and will not be affected by routine planned activities during the Otway Basin 3D MC MSS, however, this species is of relevance with regard to unplanned activities associated with a fuel oil spill (**Section 8.3**). **Relevant management plan**: Recovery Plan for Three Handfish Species 2015. Objectives of the recovery plan are to increase the understanding of the biology and ecology of Ziebell's handfish to conserve and contributed to the future recovery of the species. **Key threats**: Key threats include loss/degradation of habitat, pollution, and siltation of waterways from diffuse and point-source activities, traditional boat moorings, and the spread of the invasive Northern Pacific seastar.
Black rockcod *Epinephelus daemelii*	V	The distribution of black rockcod in Australia ranges from southern QLD through NSW to northern VIC, with records from QLD and VIC rare. The species generally inhabits near-shore rocky and offshore coral reefs at depths down to 50 m. Black rockcod have not been identified as present within the OA, however, they have been identified within the EMBA, therefore this species is of relevance with regard to unplanned activities associated with a fuel oil spill (**Section 8.3**). **Relevant management plan**: No adopted EPBC documented recovery plan for black rockcod, however, an Approved Conservation Advice is in effect from 4 April 2012, and a Listing Advice is in effect from 4 April 2012. **Key threats:** Key threats to black rockcod are incidental by-catch by recreational and commercial fishers and illegal fishing activities.

Species	EPBC Act Status	Description of species and potential to occur within the OA and EMBA
Australian grayling *Prototroctes maraena*	V	Australian grayling occur in both freshwater and marine environments; the larvae and juveniles occur in coastal waters while the adults inhabit freshwater streams and rivers (Miles *et al*., 2013). This species spawns during late summer and winter, with eggs hatching after 10 – 20 days. Larvae drift downstream to the ocean and spend around six months at sea before returning permanently to the freshwater environment (Berra, 1982; Backhouse, *et al*., 2008). The Australian grayling occurs in freshwater environments on the eastern and southern flanks of the Great Dividing Range, from Sydney, southwards to the Otway Ranges of VIC, and in TAS (DoCCEEW, 2023). As such, larvae and juveniles may occur in coastal waters of the inshore portion of the OA. Due to their freshwater distribution, adult Australian grayling will not occur within the OA during the Otway Basin 3D MC MSS; however, larvae may be present in the OA following the spawning period. **Relevant management plan**: National Recovery Plan for Australian Grayling *Prototroctes maraena.* This plan details the actions necessary to ensure the long-term survival of the species. **Key threats**: The identified threats are largely freshwater catchment based (e.g. barriers to fish migration, changes in river flows, degradation of riparian habitat, etc.) and there is no mention of any specific threats from seismic activities (e.g. noise or marine pollution.
Eastern gemfish (eastern Australian population) *Rexea solandri*	CD	Gemfish in Australian waters are divided into two fragmented and genetically isolated stocks; an eastern stock distributed from Cape Moreton, southern QLD, along the east coast to Bass Strait and the waters off TAS, and a western stock distributed from Ningaloo Reef and Geraldton through the GAB (Colgan and Paxton, 1997). The eastern stock is of relevance to the Otway Basin 3D MC MSS. The eastern gemfish population underwent a significant population reduction as the result of commercial fishing operations. Eastern gemfish inhabit deeper Continental Shelf habitats and upper slope waters from 100 to 700 m, but generally in waters 250 to 500 m. Adults are generally caught close to the seafloor but are likely to move to mid-waters at times (Kailola *et al*., 1993; Pogonoski *et al*., 2002). Larvae occur in shallow to very shallow waters (Pogonoski *et al*., 2002). Mature fish undertake annual migrations up the eastern Australian coast to spawning grounds off the NSW mid-coast, arriving between June and August (Pogonoski *et al*., 2002). Larvae have been caught in coastal waters off Sydney from July to September, and in coastal and offshore waters off northern and central NSW from August to September (Rowling and Makin, 2001). **Relevant management plan:** No adopted EPBC documented recovery plan for eastern gemfish, however, Listing Advice is in effect from 22 January 2009. **Key threats:**

Species	EPBC Act Status	Description of species and potential to occur within the OA and EMBA
Red handfish *Thymichthys politus*	CE	Red handfish are a slow-moving benthic species that is currently known from a single site at Primrose Sands Reef in Frederick Henry Bay (TAS). They occur in variety of habitats, such as on the top of rocks, amongst macro-algae and in sandy areas between rocks and the reef-sand interface at a depth distribution of 1 – 20 m (Last and Gledhill, 2009). Red handfish will not be present within the OA and will not be affected by routine planned activities during the Otway Basin 3D MC MSS, however, this species is of relevance with regard to unplanned activities associated with a fuel oil spill (**Section 8.3**). **Relevant management plan**: Recovery Plan for Three Handfish Species 2015. Objectives of the recovery plan are to increase the understanding of the biology and ecology of red handfish in order to conserve and contribute to the future recovery of the species. **Key threats**: Key threats include loss/degradation of habitat, pollution and siltation of waterways from diffuse and point-source activities, traditional boat moorings, and the spread of the invasive Northern Pacific seastar.

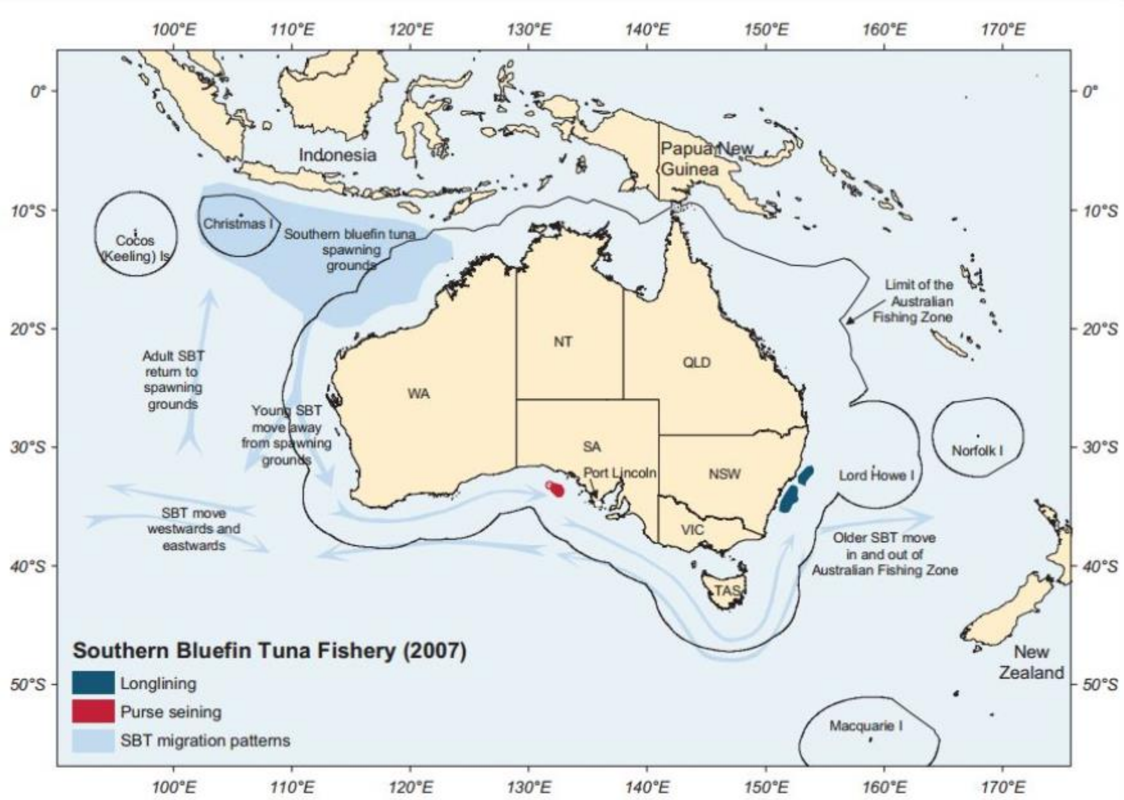
Note: The Eastern dwarf galaxias (*Galaxiella pusilla*), Yarra pygmy perch (*Nannoperca obscura*), and variegated pygmy perch (*Nannoperca variegata*) have been identified within the EPBC Act Protected Matters Report as present within the EMBA, however these species have not been included within this table as they are a freshwater species.

Key: EPBC Act Status: V= Vulnerable, CE= Critically Endangered, CD= Conservation Dependent

4.5.3.1.2 Southern Bluefin Tuna

Southern bluefin tuna are a large pelagic migratory fish of high commercial value. Generally, southern bluefin tuna are found in the southwest and southeast Atlantic Ocean, east and west Indian Ocean, and the southwest Pacific Ocean (Collette *et al.,* 2011). Within Australian waters, southern bluefin tuna occur from north Western Australia, south to South Australia, including TAS waters, and north up Australia's east coast to NSW.

Spawning of southern bluefin tuna occurs from August to April, in warm (>24 °C) surface waters. Only one spawning ground is known, in the Indian Ocean between northern Western Australia and Java (Caton, 1991; Basson *et al*., 2012) (**Figure 17**). It is considered that all southern bluefin tuna belong to a single global population.



Source: AFMA, 2023a

Figure 17 Southern Bluefin Tuna Spawning Grounds and Migration Routes

Southern bluefin tuna migrate down Australia's west coast before passing through the GAB and moving east into the Tasman Sea or west into the Indian Ocean (Basson *et al.,* 2012). During this migration, fish tend to be found in deeper waters seaward of the Continental Shelf but will come in close to shore in locations were deepwater/the shelf is close to shore. Over the summer period (December – April), southern bluefin tuna, of a range of ages and sizes are found to aggregate in large schools near the surface in the coastal waters off the southern coast of Australia, but tend to migrate to spend winters in deeper, temperate oceanic waters (DoEE, 2012).

Tagging studies undertaken on juvenile (1 – 4 years old) southern bluefin tuna revealed juveniles move from spawning grounds south of Indonesia down to the GAB and waters south of Western Australia. The GAB represents the highest preference summer location across the Southern Ocean (Basson *et al*., 2012).

From one year of age, juvenile southern bluefin tuna move south from spawning grounds, with these movements aided by the southward flow of the Leeuwin Current. The young fish are resident along the southwest coast of South Australia throughout the summer months (Fujioka *et al*., 2010), where they generally occur in waters <200 m deep (Hobday *et al*., 2009). As the fish age, they move eastward in summer; however, some fish remain in southern Western Australia waters throughout winter.

At 2 – 4 years old, southern bluefin tuna are common in the GAB during summer months, particularly in waters with a warm (17 – 22 °C) surface layer and a shallow thermocline at 60 – 80 m (Bestley *et al*., 2008). While in the GAB, the young fish aggregate in large schools and spend a large proportion of the day in the upper 100 m of the water column (Bestley *et al*., 2009).

Aerial surveys and spotting data from spotter planes in the commercial tuna fishery have identified the highest densities of southern bluefin tuna occur in a band inside and parallel to the Continental Shelf break, with the location of aggregations varying between years (Hobday *et al*., 2015). While in the GAB, individual tuna have been observed to exhibit short-term school fidelity, suggesting that schools break-up and reform relatively frequently (Willis and Hobday, 2007), and that schooling behaviour is not a serious issue for juvenile tuna (Basson *et al*., 2012).

As surface waters cool and upwelling ceases, the tuna begin to move out of the GAB. 2 – 3-year-old fish carry out annual migrations between GAB summer feeding grounds and winter-feeding grounds in the central and southeast Indian Ocean or Tasman Sea (Basson *et al*., 2012). Most tuna move west from the GAB into the Indian Ocean; a change in preference for this location from the Tasman Sea since the 1990s and 2000s (Basson *et al*., 2012; Evans *et al*., 2017). The findings of Basson *et al*. (2012) on tuna migrations to and from the GAB can be summarised as follows:

- Summer: juveniles are primarily resident in the GAB and off southern Australia, with fish almost exclusively resident in February and March. The highest level of residency in southern Australia occurs in January through to May. Summer site fidelity is high, with all tagged fish returning to SA in summer;
- Winter: some individuals remain in waters off southern Australia, with most moving to Indian Ocean and Tasman Sea feeding grounds. Tagging data suggests a less strong winter site fidelity, with fish often switching between the Indian Ocean and Tasman Sea foraging grounds in consecutive winters;
- Juvenile southern bluefin tuna migrate throughout the latitudinal band of approximately 30 – 40°S;
- Migrations out of the GAB to winter feeding grounds begin in May and continue to September, with most movements occurring in June to August. Migrations back to GAB summer feeding grounds begins in October and continues through to January, with the majority occurring in November and December;
- Movements out of the GAB is more gradual than the return to the GAB, with fish departing over a wide range of times and moving to a wide range of locations; and
- Juvenile southern bluefin tuna can travel up to 200 km per day when migrating, although they move on average 100 km per day. When resident, juveniles move relatively little longitudinally, but may move up to 70 km per day.

Patterson *et al.* (2018) further states that southern bluefin tuna migrations are unusual in that movement is specific to juveniles and the timing of migrations is highly variable (i.e. not synchronised), with no obvious latitudinal component that could be associated with seasonal temperature, or evidence of a correlation with environmental drivers such as sea surface temperature and surface chlorophyll- α. However, Patterson *et al*. (2018) reports on the movements of 110 tagged juvenile southern bluefin tuna between 1998 and 2011, whereby the juvenile fish within the GAB were associated with low surface productivity, consistent with previous findings of southern bluefin tuna but inconsistent with other bluefin tuna species (e.g Pacific) whose movements tracked seasonal productivity maxima (Boustany *et al.,* 2010; Whitlock *et al*., 2015). Potential explanations for this are:

- Southern bluefin tuna prefer to hunt in clear waters away from areas of high turbidity such as those associated with high primary productivity;
- The energy transfer from primary to intermediate (i.e. tuna prey) levels in the food web involves a time lag, offsetting the presence of apex predators from high levels of primary productivity; and
- Areas of concentrated productivity are likely to operate at smaller spatial scales than those at the scale that tuna residency was investigated.

The distribution of juvenile southern bluefin tuna within the GAB is poorly understood; however, anecdotal evidence and tagging studies has been used to describe seasonal movements throughout the GAB over summer – autumn. These suggest that the smaller, younger southern bluefin tuna (1 – 2 year olds) are more associated with inshore regions in Western Australia (Fukioka *et al*., 2010), with older fish (2 – 4 year olds) more abundant in central regions of the GAB close to the shelf break (**Figure 19**) (Eveson and Farley, 2016; Evans *et al.,* 2017a).

Peak periods in juvenile southern bluefin tuna residency within the GAB broadly coincides with the high abundance of Australian sardines/pilchards (*Sardinops sagax*) (Ward *et al*., 2006a; Itoh *et al*., 2011), suggesting juveniles move to waters of the GAB following the high density of prey.

Source: Evans *et al*., 2017a

Figure 19 Monthly Aggregated Counts of Position Estimates Derived from Juvenile Southern Bluefin Tuna Tagged with Archival Tags 1998 – 2011 Including Bathymetric Contour Lines Associated with Shelf Breaks (black)

Southern bluefin tuna continue to undertake the above-described seasonal migrations until they reach approximately five years of age, after which they disperse throughout waters in the Pacific, Indian and Atlantic Oceans (Hobday *et al.,* 2015) during winter, before migrating to spawning grounds from spring to autumn (Caton, 1991). Adults present in the Tasman Sea move south into waters around TAS in the end of spring/beginning of summer. Following this, they move south of Australia, then north up the Western Australia coastline towards spawning grounds (**Figure 20**). Tagged sub-adult and adult southern bluefin tuna caught in the Tasman Sea demonstrate temperature preferences for waters 18 – 20 C and depths <250 m, although depths >600 m are also utilised (Patterson *et al*., 2008). Adult movements are relatively fast and direct, lasting approximately 110 days (Hobday *et al*., 2015). Based on the tracks of tagged adult southern bluefin tuna depicted in **Figure 20**, adults may be present in the OA from October to December (Patterson *et al*., 2015).

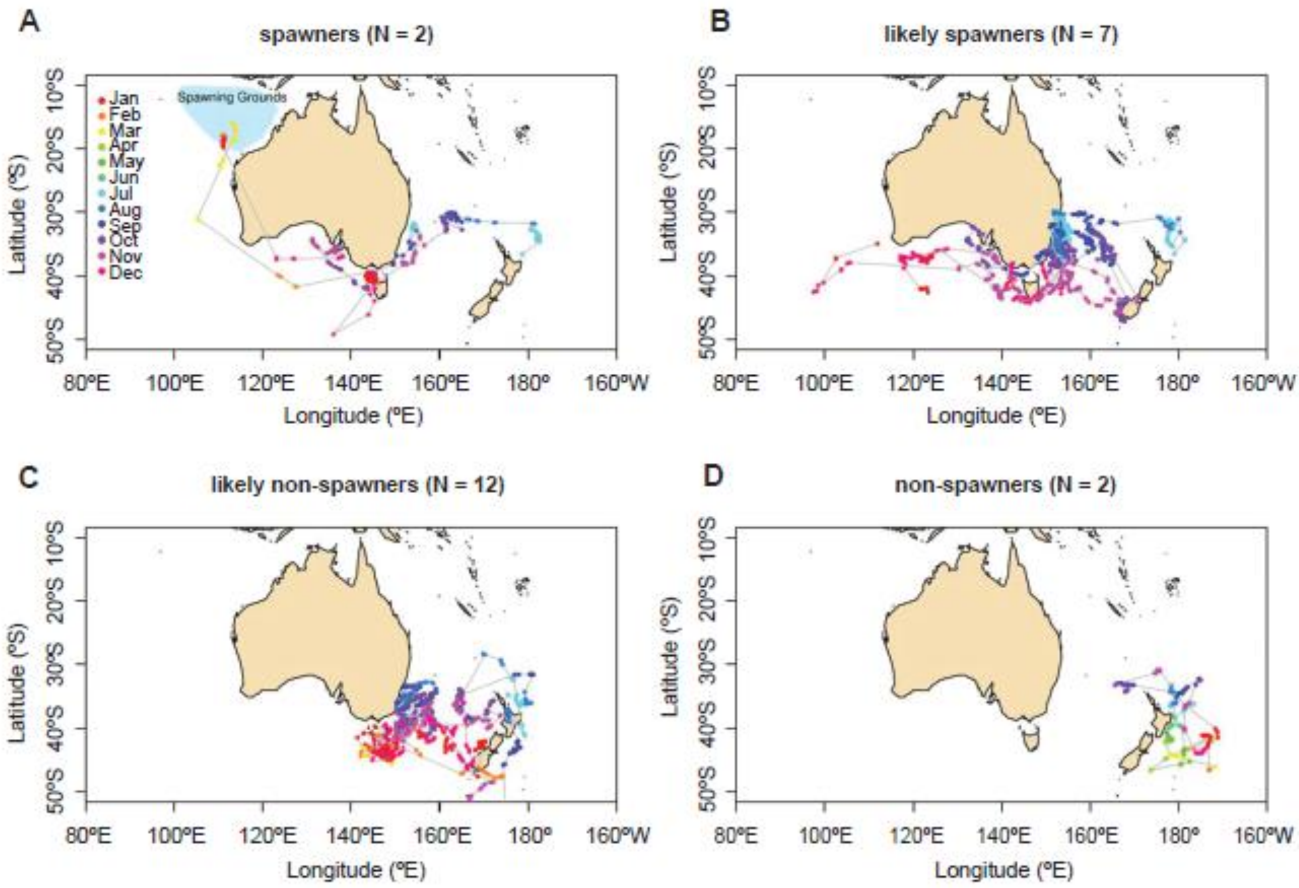

Figure 20 Movements of Adult Southern Bluefin Tuna Categorised by Putative Spawning Behaviour

Source: Hobday *et al.,* 2015

Key: (A) spawners showing movements from the tagging region to the spawning grounds (defined in blue); (B) likely spawners which made large westward migrations; (C) likely non-spawners remained in the Tasman Sea region until late in the spawning season and (D) non-spawners which remained resident in the Tasman for a full spawning cycle.

4.5.3.2 Commercially Targeted Fish Stocks

The SEMR provides fishing grounds for several commercial fisheries which target a variety of pelagic and demersal fish species. The stock assessments of commercially targeted species likely to be captured within, or directly adjacent to the OA, are provided in **Table 21**. This includes reproduction and recruitment strategies and spawning seasons of each species as well as their distribution and habitat. Stock assessments have been included from the VIC, South Australia, TAS and Commonwealth commercial fisheries.

Table 21 Stock Assessment of Commercially Targeted Species Likely to be Captured Within or Directly Adjacent to the OA

Species	Distribution and habitat	Depth range (m)	Reproduction and Recruitment	VIA	SA	TAS	Comm.	Spawning season
Australian herring *Arripis georgianus*	Western Australia – NSW Bays and estuaries, rocky reefs, seaweed	1 – 5	Partial spawners 100,000 eggs on average Planktonic eggs and larvae	N/A	Sustainable	N/A	N/A	May – June in Western Australia
Barracouta *Thyrsites atun*	Midwest Western Australia – QLD, around TAS Open water, coastal bays	0 – 550	Eggs are pelagic Juveniles inhabit sheltered waters of southern bays and estuaries.	N/A	N/A	Undefined	N/A	October – March in TAS (spawning ground for all southern stock)
Bigeye ocean perch *Helicolenus barathri*	South-eastern Australia Continental shelf and slope	200 – 700	Maturity at 5 – 7 years Lecithotrophic viviparous (fertilisation and larval development is internal) 150,000 – 200,000 eggs	N/A	N/A	N/A	Sustainable	June – February
Bight redfish *Centroberyx gerrardi*	Bass Strait – Western Australia Rocky reefs and muddy substrates.	< 500	Maturity at 9 years Low fecundity but multiple occasions over season	N/A	Sustainable	N/A	N/A	Summer – autumn
Blacklip abalone *Haliotis rubra rubra*	State-wide	0 – 25	Dioecious broadcast spawners Larvae are lecithotrophic and pelagic Short larval phase: 5 – 15 days and dependent on water temperature. Local recruitment	Sustainable	Sustainable	Sustainable	N/A	Spring – autumn with peaks in late Summer and early Spring
Blue grenadier *Macruronus novaezelandia*	GAB and off VIC and TAS. Continental slope, juveniles in shallower bays. Move up the water column at night.	200 – 700	Maturity at 4 – 7 years. 1 million eggs in one spawning event. Main spawning ground in off the west coast of TAS	N/A	N/A	N/A	Sustainable	Winter – early spring

Species	Distribution and habitat	Depth range (m)	Reproduction and Recruitment	VIA	SA	TAS	Comm.	Spawning season
Blue mackerel *Scomber australasicus*	Bass Strait – Western Australia Schooling pelagic species. Juveniles inhabit shallower bays	<200	Maturity at 3 years. Serial spawners (multiple events over season) Release ~70,000 eggs per event.	N/A	Sustainable	N/A	N/A	Spring – summer off NSW and QLD
Blue morwong *Nemadactylus valenciennesi*	Southern coastal waters of Australia's mainland Reef-associated	3 – 240	Gonochorists (remain same sex) lengthy pelagic larval phase	N/A	N/A	N/A	Depleting	Unknown
Blue warehou *Seriolella brama*	NSW – South Australia, TAS and New Zealand Inshore reefs/harbours as juveniles. Adults inhabit continental shelf and slopes. Schooling fish near seabed.	50 – 400	Maturity at 3 years. Spawn 3 times a season (430,000 – 1,350,000 eggs per event). Larvae restricted to shelf and slope waters. Main spawning grounds off western VIC and TAS	N/A	N/A	Depleted	Depleted	Winter – early spring.
Blue-eye trevalla *Hyperoglyphe Antarctica*	South to eastern coastlines Rocky ground on continental slope, juveniles in surface waters associated with debris. Move up the water column at night	200 – 900	Maturity at 11 – 12 (females) or 8 – 9 (males). Eggs released in 3 – 4 batches (2 – 11 million eggs per season)	N/A	N/A	N/A	Sustainable	Summer – autumn off central NSW to north-east TAS

Species	Distribution and habitat	Depth range (m)	Reproduction and Recruitment	VIA	SA	TAS	Comm.	Spawning season
Bluethroat wrasse *Notolabrus tetricus*	State-wide coastal waters Territorial, inhabiting rocky reefs.	<30	Single male with 'harem' of females Maturity at 4 – 8 years High degree of site fidelity once settled Extensive larval dispersal Planktonic larval duration: 44 to 66 days Protogynous hermaphrodite	Sustainable	Sustainable	Sustainable	N/A	Spring
Bronze whaler *Carcharhinus brachyurus*	NSW – Geraldton in Western Australia. Found on continental margins, sometimes large bays. Migratory within range. North: spring – summer, South: autumn – winter	0 – 360	Viviparous, 7 – 10 pups a season. Distinct pairing with embrace.	Undefined	N/A	N/A	N/A	Occur all year but peaks in summer
Commercial Scallop *Pecten fumatus*	TAS – VIC Muddy – coarse sandy seafloor Mainly sedentary	10 – 120	Maturity at 1 year Spawn in second year. Hermaphrodites Broadcast spawners Fecundity increases with size and age	N/A	N/A	N/A	Sustainable	Winter – spring triggered by increase in water temperature
Common jack mackerel *Trachurus declivis*	Western TAS to southern Western Australia. Pelagic schooling fish in waters off continental shelf	20 – 300	Maturity at 3 – 4 years Spawning begins of southeast coast of Australia and progresses southwards. Serial spawners (34,000 eggs per event).	N/A	N/A	N/A	Sustainable	Spring – summer

Species	Distribution and habitat	Depth range (m)	Reproduction and Recruitment	VIA	SA	TAS	Comm.	Spawning season
Deepwater flathead *Platycephalus conatus*	West TAS through GAB Demersal fish on continental shelf and slope. Buried in sand or mud.	70 – 490	Maturity at 5 – 6 years (females) or 4 – 5 year (males). Aggregate for spawning. 0.5 – 3.5 million eggs per season	N/A	N/A	N/A	Sustainable	Late spring – autumn
East Australian salmon *Arripus trutta*	TAS - QLD Open water, sandy seabeds.	<30	Pelagic spawners Planktonic phase for eggs, larvae and juveniles. Juveniles appear in shallow Tasmanian waters between January and September.	NA	NA	Sustainable	NA	October to March, off NSW
Elephantfish *Callorhinchus milii*	Southern Australia and NZ Shallow bays and estuaries as juveniles, move deeper as adults.	<200	Maturity at 4 – 5 years (females) or 3 years (males). Oviparous Eggs deposited in sand/mud near river mouths. Hatch after 8 months	N/A	N/A	N/A	Sustainable	February
Gemfish *Rexea solandri*	West edge of Bass Strait through GAB Bottom dwelling schooling fish. Juveniles are pelagic.	100 – 800	Maturity at 4 – 6 years (female) or 3 – 5 years (male). Spawning dynamics not known for western stock.	N/A	N/A	N/A	Sustainable	summer
Giant crab *Pseudocarcinus gigas*	WA – TAS Seaweed, reef, sand habitats	110 – 400 (core range)	Planktonic larval duration: ~50 days Larval release occurring along the edge of the continental shelf Highly fecund Females store sperm for successful breeding seasons	Sustainable	Sustainable	Depleted	N/A	Autumn - spring

Species	Distribution and habitat	Depth range (m)	Reproduction and Recruitment	VIA	SA	TAS	Comm.	Spawning season
Gould's squid *Nototodarus gouldi*	Southern QLD – mid-Western Australia and TAS Open water. Coastal, inner shelf and shelf break	< 600	Spawns once and then die Egg mass are free-floating gelatinous sphere and contains several thousands of eggs Highly variable recruitment	N/A	N/A	Sustainable	Sustainable	Year-round
Greenlip abalone *H. laevigata*	Southern mainland and TAS Rocky reefs	< 40	Maturity at 2 years. Dioecious broadcast spawners Larvae are lecithotrophic and pelagic Local recruitment	N/A	Depleting	Depleting	N/A	Spring – autumn with peaks in late summer and early spring
Gummy shark *Mustelus antarcticus*	State-wide, inshore coastal waters Demersal species on or near seabed on continental shelf	80 – 350	Maturity at 4 – 5 years. Low fecundity (an average of 14 pups per breeding cycle) and an 11 to 12 month gestation period.	Sustainable	Sustainable	N/A	Sustainable	November to December in shallow coastal waters
Hapuku Commonwealth *Polyprion oxygeneios*	Southern waters, Western Australia – NZ Rough ground on continental shelf. Juveniles pelagic with drifting weed	50 – 850	Extended larval/juvenile phase (years) Primary gonochrists.	N/A	N/A	N/A	Undefined	June - August
Jackass morwong *Nemadactylus macropterus*	Tasmania through GAB Demersal species near continental shelf and slope. Juveniles near shallow reefs.	10 – 400	Maturity at 3 years. Multiple spawning events Extended pelagic post larval phase ('paperfish') for 9 – 12 months	N/A	N/A	N/A	Sustainable	Late summer - autumn

Species	Distribution and habitat	Depth range (m)	Reproduction and Recruitment	VIA	SA	TAS	Comm.	Spawning season
John dory *Zeus faber*	Coastal and continental-shelf waters around most of Australia Demersal species, open sand, mud, rocky grounds and reefs	5 – 360	Maturity at 3 – 5 years. Multiple spawning events a season Fecundity increases with body size	N/A	N/A	N/A	Sustainable	Summer – autumn in NSW
King George whiting *Sillaginodes punctatus*	Southeast Australia Seagrass and sandy habitats. Deeper waters as they get older	2 – 200	High Fecundity Moderate growth rate Offshore spawning and long larval dispersal Serial batch spawners	Sustainable	Sustainable	N/A	N/A	April - June
Maori octopus *Macroctopus maorum*	Southeastern Australia Rocky reefs, crevasses	0 – 549	Eggs incubate benthically with maternal protection Larvae enter a planktonic phase with relatively high dispersal potential	Sustainable	N/A	N/A	N/A	Undefined
Mirror dory *Zenopsis nebulosus*	Throughout southern Pacific and southern Australia Near seabed, solitary species	50 – 600 m	Maturity at 5 years Low fecundity Possible serial spawners	N/A	N/A	N/A	Sustainable	Winter in NSW
Ocean jacket *Nelusetta ayraudi*	Southern Australia Juveniles inhabit estuaries and sheltered bays with sea grass. Adults inhabit rocky reefs, sandy-mud bottoms, sponge-algae gardens.	2 – 250	Maturity at 2.5 years Spawning aggregations at 85 – 200 m Broadcast spawners with no parental egg care	N/A	N/A	N/A	Sustainable	3-month period Peaks in autumn (South Australia) or late winter (NSW)

Species	Distribution and habitat	Depth range (m)	Reproduction and Recruitment	VIA	SA	TAS	Comm.	Spawning season
Orange roughy *Hoplostethus atlanticus*	West TAS – south-east South Australia Steep continental slope and ridges, rough bottoms. Sedentary species but can aggregate	700 – 1400	Maturity at 27 – 32 years. Spawn over 1 – 2 weeks. Low fecundity. Eggs float to surface then sink to hatch 10 – 20 days later.	N/A	N/A	N/A	Depleted	Mid July – late August.
Pale octopus *Octopus pallidus*	GAB – TAS – southern NSW Soft sediment habitats	< 600	Semelparous (spawn once then die) Few (450 – 800) very large eggs No larval phase after hatching with hatchlings resembling adults in both appearance and behaviour Limited dispersal	NA	NA	Depleting	NA	Spawns year-round with peaks in late summer/early autumn
Pink ling *Genypterus blacodes*	South-eastern coastline of Australia. Continental shelf and slope, rock ground to soft sand/mud	20 – 1000	Maturity at 7 – 12 years. Serial spawners Egg batches make floating mass	N/A	N/A	N/A	Sustainable	Late winter - spring
Pipi *Donax deltoides*	State-wide but 2 stocks at either end of Bass Strait	2 – 10	Recruits are likely to be self-seeded Highly fecund Widely dispersed in the larval stage.	Sustainable	N/A	N/A	N/A	Year-round
Purple wrasse *N. fucicola*	Territorial, inhabiting rocky reefs	1 – 90	Single male with 'harem' of females Maturity at 3 years Highly fecund, gonochoristic species Planktonic larval duration: 40 to 87 days	Sustainable	N/A	Sustainable	N/A	Spring

Species	Distribution and habitat	Depth range (m)	Reproduction and Recruitment	VIA	SA	TAS	Comm.	Spawning season
Ribaldo *Mora moro*	Rough seabeds and seamounts on the continental shelf of south-eastern Australia.	450 – 2,500	Maturity at 14 years (females) or 8 years (males) Juveniles may be pelagic	N/A	N/A	N/A	Sustainable	Winter - spring
Sawsharks *Pristiophorus spp.*	Southern and south-eastern coasts of Australia but are mainly caught in Bass Strait.	< 600	Maturity at 2 years. Aplacental viviparous with 12-month gestation. 5 – 10 pups per litter, breed every second year.	N/A	N/A	N/A	Sustainable	Winter
School shark *Galeorhinus galeus*	Southern coast of Australia Continental shelf and slope, migrating up to 1400 km long southern coast. Move up water column at night	< 550	Maturity at 10 years (females) or 8 years (males) Ovoviviparous with gestation of 12 months. 15 - 43 pups born every 2 – 3 years in shallow bays	N/A	Depleted	N/A	N/A	Early summer
Silver trevallies *Pseudocaranx georgianus, P. wrighti*	Southern temperate Australia Schooling species in estuarine and coastal waters. Open ground, sand/gravel bottoms	10 – 230	Maturity at 2 – 4 years. Spawning in estuaries and deep waters Serial spawners Low fecundity	N/A	N/A	N/A	Sustainable	Spring - autumn
Silver warehou *Seriolella punctata*	Southern and eastern Australia Continental shelf and slope as adults, juveniles occur in bays and inlets. Schooling species	50 – 600	Maturity at 4 years. High fecundity. Spawning timing varies with location	N/A	N/A	N/A	Sustainable	Late winter – early spring

Species	Distribution and habitat	Depth range (m)	Reproduction and Recruitment	VIA	SA	TAS	Comm.	Spawning season
Snapper *Chrysophrys auratus*	VIC – Investigator Strait, South Australia Adults associated with deeper offshore reefs, juveniles enter bays and estuaries.	1 – 200	Mature at 2 – 7 years High fecundity Serial spawners	Sustainable	N/A	N/A	N/A	When water temperature is 18°C
Southern bluefin tuna *Thunnus maccoyii*	Global Temperate Oceans Juveniles often closer to shore	< 500	Maturity at 11 – 12 years High fecundity (14 – 15 million eggs per season). Migrate south after spawning Juveniles typically migrate through the GAB heading east between December and April	N/A	N/A	N/A	Recovering	Spring – summer in North-east Indian Ocean
Southern Garfish *Hyporhamphus melanochir*	Lancelin, Western Australia – Southern NSW and TAS Schooling fish on seagrass. Near surface at night.	0 – 40	Serial spawner Asynchronous oocyte development	N/A	Sustainable	N/A	N/A	October – March
Southern rock lobster *Jasus edwardsii*	Southern Australia Rocky reefs and crevices	<150	Extensive and protracted pelagic larval dispersal phase - 12–18 months Site attached once settled	Sustainable	Sustainable	Sustainable	N/A	April – July
Southern sand flathead *Platycephalus bassensis*	Endemic to temperate Australian coastal waters and other bays and inlets. Sandy bottoms	0 – 100	Multiple spawning events per season Variability in egg release patterns.	Sustainable	Undefined	N/A	N/A	October – March

Species	Distribution and habitat	Depth range (m)	Reproduction and Recruitment	VIA	SA	TAS	Comm.	Spawning season
Striped trumpeter *Latris lineata*	Sydney, NSW – southern Western Australia, TAS and New Zealand Exposed reefs and rocky bottom	300	Multiple spawners, Highly fecund (100,000 to 400,000 eggs Small pelagic eggs Extended larval phase of: 9 months No information on size and timing of settlement	N/A	N/A	Recovering	N/A	July – early October
Tiger flathead *Platycephalus richardsoni*	Endemic to south east of Australia Mud or sandy bottoms. Juveniles inhabit shallower waters	10 – 400	Maturity at 3 – 5 years Variation in spawning with location. High fecundity Mature with migrate to shallow waters for spawning	N/A	N/A	N/A	Sustainable	Spring – autumn
Western Australian salmon *Arripis truttaceus*	Shark Bay, Western Australia – VIC and TAS Juveniles inhabit soft substrates and coastal waters. Adults form schools in reefs and open water	0 – 30	Maturity at 3–5 years Spawn in south-west WA Nursery grounds in South Australia, VIS and TAS	Sustainable	N/A	N/A	N/A	April – May (migration to Western Australian waters)
Yelloweye mullet *Aldrichetta forsteri*	Mid Western Australia – NSW and TAS Nearshore and estuaries	0 – 10	Gonochristic Spawning occurs in estuaries Low fecundity Pelagic egg development.	N/A	Sustainable	N/A	N/A	March – August
Yellowtail kingfish *Seriola lalandi*	Temperate waters of Atlantic, Pacific and Indian Oceans Rocky reefs and adjacent areas	> 300	Maturity at 5 -7 years External fertilisation Rapid growth of larvae and juveniles (2 – 3 kg in first year)	N/A	N/A	N/A	Sustainable	Spring – summer

4.5.3.3 Elasmobranchs

4.5.3.3.1 Elasmobranch Listed Threatened and Migratory Species

11 threatened and/or migratory elasmobranch species were identified within the EPBC Act Protected Matters Report as potentially occurring in the OA and/or the wider EMBA. A description of the threatened and/or migratory elasmobranchs identified in the EPBC Act Protected Matters Report is provided in **Table 22**.

Table 22 EPBC Act List of Threatened and Migratory Elasmobranchs Identified within the OA and/or EMBA

Species	EPBC Act Status/ Migratory Status	Description of species and potential to occur within the OA and EMBA
White Shark *Carcharodon carcharias*	V M	White sharks are a large (grow to a minimum length of 6 m and can weigh up to 3,000 kg (Mollet and Cailliet, 1996; Last and Stevens, 2009)) circum-globally distributed marine apex predator that inhabits temperate and sub-tropical waters (Compagno, 2001). Perceived worldwide declines in white shark populations have resulted in protection of the species. In Australia, white sharks are broadly distributed throughout southern waters from North West Cape, Western Australia to southern Queensland (Last and Stevens, 2009). There are two sub-populations of white sharks in Australian waters: the eastern (NSW, VIC, TAS, Queensland and New Zealand) and the southern-western (South Australia, Western Australia, and western-Vic). The OA is within the known distribution of the southern-western population (Department of Primary Industries and Regional Development (DPIRD) n.d.). Accurate population assessments are not yet possible for any region (Bruce, 2008). Satellite tagging studies of white sharks in Australia have indicated that most movement patterns are restricted to coastal, continental shelf or slope waters (Bradford *et al*., 2020). In inshore waters, white sharks are commonly found in the vicinity of islands, and often surrounding fur seal and Australian sea lion colonies. Bradford *et al*. (2020) documented satellite tracked movement of white sharks, with females covering a broader longitudinal range than males, with an average track length of approximately 3,630 ± 750 km for females and approximately 2,525 ± 457 km for males. Key locations for white sharks include Wilsons Promontory, VIC (particularly juveniles) and the Neptune Islands off the Eyre Peninsula, SA (CoA, 2013a). The OA overlaps with the known distribution of white sharks. There are four white shark BIAs that overlap with the OA, and an additional breeding (nursery area) BIA and two foraging BIA which also overlap with the EMBA (285 km, 15 km, and 375 km from the OA respectively) (see **Figure 21**). Given the wide-ranging distribution of this species, and identification of several BIAs within the OA and EMBA, white sharks are likely to be encountered during the Otway Basin 3D MC MSS. **Relevant management plan**: Recovery Plan for the White Shark (*Carcharodon carcharias*). The overarching objective of the 10 specific objectives of the white shark recovery plan is to assist the recovery of the white shark in the wild, throughout its range in Australian waters, with a view to: 1) improving population status, leading to future removal of the white shark from the threatened species list of the EPBC Act, and 2) ensuring that anthropogenic activities do not hinder the recovery of the white shark in the near future, or impact on the long term conservation status of the species. **Key threats**: 1) Mortality related to incidental (accidental or illegal) capture by commercial and recreational fisheries, including issues of post release mortality; 2) Mortality related to shark control activities such as beach meshing or drumlining (east coast population). Exposure to underwater noise is not identified as a threat to the recovery of the species.

Species	EPBC Act Status/ Migratory Status	Description of species and potential to occur within the OA and EMBA
Little gulper shark *Centrophorus zeehaani*	CD N/A	Little gulper sharks are small, deepwater sharks that are endemic to Australian waters. This species inhabits the upper slope between 180 m and 900 m (Williams *et al*., 2012) of the southern Continental Shelf. Little gulper shark is found off the southern Australian coast from near Warrnambool to south of Ceduna and from the western side of the GAB up the west coast to Mandurah. It is absent off southern TAS through Bass Strait (Williams *et al.,* 2012). The species is mainly demersal with a depth range of 190 – 900 m and a core range of 200 – 800 m (Williams *et al*., 2012). **Relevant management plan**: No adopted EPBC documented recovery plan for little gulper shark, however, a Listing Advice is in effect from 14 March 2013. **Key threats**: The main threat to the little gulper shark is population reduction caused by past fishing pressure in state and Commonwealth-managed commercial fisheries operating on the upper-slope.
School shark *Galeorhinus galeus*	CD N/A	School sharks occur globally in temperate waters. They are mostly found in demersal waters over the Continental and insular shelves, but also occur over the upper slopes, in depths from near-shore to 550 m (Last and Stevens, 1994). Inshore areas are particularly important as birthing and nursery areas (TSSC, 2009). **Relevant management plan**: No adopted EPBC documented recovery plan for school shark, however, a Listing Advice is in effect from 22 January 2009. **Key threats**: The main threat to the school shark is fishing pressure (both in Australia and globally) across its range and at nursery areas as well as habitat degradation at nursery areas (often located in inshore bays and estuaries).
Grey nurse shark (east coast population) *Carcharias taurus*	CE N/A	Grey nurse sharks in Australia are restricted to two populations: the east coast from southern QLD to northern NSW, and around the south-west coast of Western Australia. Due to the decline in numbers of the east coast population, this population is now listed as Critically Endangered. This species is uncommon in VIC, South Australian, and TAS waters, and has not been found in the GAB (Pogonoski *et al*., 2002), therefore is it unlikely to be encountered during the Otway Basin 3D MC MSS. However, a foraging and migration BIA for this species overlaps with the EMBA (**Figure 21**) and is therefore relevant to unplanned activities associated with a fuel oil spill (**Section 8.3**). **Relevant management plan**: Recovery Plan for the Grey Nurse Shark (Carcharias taurus) (DoE, 2014). The overarching objective of this recovery plan is to assist the recovery of the grey nurse shark in the wild, throughout its range in Australian waters with a view to: 1) improving the population status, leading to future removal of the grey nurse shark from the threatened species list of the EPBC Act; and 2) ensuring that anthropogenic activities do not hinder the recovery of the grey nurse shark in the near future, or impact on the conservation status of the species in the future. **Key threats**: The main threats to the grey nurse shark (east coast population) are mortality related to incidental capture by commercial and recreational fisheries, and mortality related to shark control activities such as beach meshing or drumlining. Other potential threats to the species include impacts from ecotourism, collection for public aquaria, pollution and disease and ecosystem effects because of habitat modification and climate change.

Species	EPBC Act Status/ Migratory Status	Description of species and potential to occur within the OA and EMBA
Harrison's dogfish *Centrophorus harrissoni*	CD N/A	Harrison's dogfish is a small, deepwater shark with a core range that is continuous from north of Evans Head in NSW through waters off the coast of VIC, to Cape Hauy in TAS. It is not known from South Australian waters (Williams *et al*., 2012). This species is largely demersal and has been recorded in water depths between 100 m (Williams *et al.,* 2012) and 1050 m (Daley *et al.,* 2002), with a core depth range of 200 – 900 m (Williams *et al*., 2012). Due to the likely distribution of Harrion's dogfish being far from the OA, it is unlikely this species will be affected by activities associated with the Otway Basin 3D MC MSS, but is of relevance to unplanned activities associated with a fuel oil spill (**Section 8.3**). **Relevant management plan**: No adopted EPBC documented recovery plan for Harrison's dogfish, however, a Listing Advice is in effect from 14 June 2013. **Key threats**: The main threat to this species is past fishing pressure in both state and Commonwealth-managed commercial fisheries operating on the upper-slope.
Maugean skate *Zearaja maugeana*	E N/A	The Maugean skate inhabits two small estuarine systems in southwest TAS; Macquarie Harbour and Bathurst Harbour. Within these harbours, Maugean skate inhabit low-nutrient brackish water, 5 – 7 m deep. The total range of this species is thought to be no more than 100 km^2, and the population is estimated at 1,000 individuals (TSSC, 2004). Due to highly restricted distribution of this species, this species will not be affected by activities associated with the Otway Basin 3D MC MSS but is of relevance to unplanned activities associated with a fuel oil spill (**Section 8.3**). **Relevant management plan**: No adopted EPBC documented recovery plan for Maugean skate, however, a Listing Advice is in effect from 4 March 2004 and an Approved Conservation Advice is in effect from 3 July 2008. **Key threats**: The main potential threats to this species are trace metal pollution from historic mining operations in Macquarie Harbour, incidental capture in fishing activities, the introduction of non-native marine species, changes to water nutrient levels through discharge from cruise ships and fishing vessels, and an increase in tourism pressure. .

Species	EPBC Act Status/ Migratory Status	Description of species and potential to occur within the OA and EMBA
Whale Shark *Rhincodon typus*	V M	Whale sharks are the largest known living fish species, reaching up to 12 m in length, although more commonly measuring 4 – 10 m (Colman, 1997). They are an oceanic and coastal, tropical to warm-temperate pelagic species that is generally encountered close to or at the surface but can make dives to around 1000 m in search of prey (Compagno, 1984). In Australia, the Whale Shark is most seen in waters off northern Western Australia, the Northern Territory and QLD, with occasional observations in VIC and South Australia (Compagno, 1984; Last and Stevens, 1994). Individuals are unlikely to be present in the OA and therefore will not be affected by routine activities associated with the Otway Basin 3D MC MSS, however, they are of relevance to unplanned activities associated with a fuel oil spill (**Section 8.3**). **Relevant management plan**: No adopted EPBC documented recovery plan for whale shark. A Whale Shark Recovery Plan 2005-2010 is provided on the federal register of legislative instruments. The objective of the whale shark recovery plan 2005-2010 is to maintain existing levels of protection for the whale shark in Australia while working to increase the level of protection afforded to the whale shark within the Indian Ocean and Southeast Asian region to enable population growth so that the species can be removed from the threatened species list of the EPBC Act. **Key threats**: The main threat to the whale shark occurs outside Australian waters and is commercial harvesting by other range states of the whale shark. The potential future threats to whale sharks visiting Australian waters are competition with fisheries, habitat damage, pollution and marine debris, climatic and ocean change, predation, disease, and direct disturbance from tourism, research, or interference. At present none of these potential threats appear to have an impact on the numbers of whale sharks visiting Australian waters. Underwater noise is not specifically listed as a threat to the species in the Whale Shark Recovery Plan 2005-2010. Sound from commercial vessels has been identified to disturb whale sharks (DpaW, 2013).
Shortfin mako shark *Lsurus oxyrinchu*	N/A M	The shortfin mako is a large (up to 4 m length) and fast (up to 18.8 ms^{-1}) pelagic mackerel shark (Last and Stevens, 2009) that has a circum-global distribution. Shortfin mako are highly migratory and inhabits tropical and temperate waters to depths of 888 m, although they are rarely encountered in waters with temperatures less than 16 °C (Rigby *et al.*, 2019a). It is widespread in Australian waters having been recorded in offshore waters all around the continent's coastline (Last and Stevens, 2009). There are no BIAs recognised for shortfin mako in either the OA or wider EMBA; however, given the wide-ranging distribution of this species, and the known site fidelity to areas either side of the OA, shortfin mako are likely to be encountered during the Otway Basin 3D MC MSS. **Relevant management plan**: There is currently no adopted EPBC documented recovery plan for shortfin mako. **Key threats**: Globally, the main threat to the shortfin mako is historic and ongoing fishing pressure.

Species	EPBC Act Status/ Migratory Status	Description of species and potential to occur within the OA and EMBA
Porbeagle *Lamna nasus*	N/A M	The porbeagle primarily inhabits oceanic waters and areas around the Continental Shelf, using a broad vertical range of the water column to depths of 1,809 m (Rigby *et al*., 2019b). Porbeagles are known to undertake seasonal migrations, the movements and timing of which is not well understood (Saunders *et al*., 2011). Individuals have been tracked to cover distances of 1,500 – 1,800 km along continental shelves and crossing the Atlantic Ocean between Europe and North America (Francis *et al*., 2002). Large distance migrations are thought to be due to searching for better feeding environments or for mates (Saunders *et al*., 2011). In Australia, the porbeagle occurs in waters from southern Queensland to south-west Australia (DoE, 2023). Given the wide-ranging distribution of this species, porbeagle sharks may be encountered during the Otway Basin 3D MC MSS. **Relevant management plan:** There is currently no adopted EPBC documented recovery plan for shortfin mako. **Key threats:** Globally, the main threat to the porbeagle is overfishing.
Oceanic whitetip shark *Carcharhinus longimanus*	N/A M	The oceanic whitetip shark is a deep-water pelagic species inhabiting tropical to warm-temperate waters (Compagno, 1984). Oceanic whitetip sharks prefer water temperatures above 20 °C and can reach depths of >180 m (Castro *et al.*, 1999). Within Australian waters, the oceanic whitetip shark is found from WA, through parts of the NT and down to Sydney (Last and Stevens 2009). Given the species distribution is a considerable distance from the OA on the east coast, oceanic whitetip sharks are unlikely to be encountered during the Otway Basin 3D MC MSS. This species is however of relevance to unplanned activities associated with a fuel oil spill (**Section 8.3**). **Relevant management plan**: No adopted EPBC documented recovery plan for oceanic whitetip shark
Giant manta ray *Manta birostris*	N/A M	The giant manta ray has a circum-tropical and semi-temperate distribution throughout the world's major oceans. Within this broad range, populations appear to be sparsely distributed and highly fragmented (Marshall *et al.*, 2018a). The giant manta ray appears to be a seasonal visitor to coastal or offshore sites and are capable of large-scale movements of >1,000 km (Kashiwagi *et al.*, 2011). Whilst largely solitary, giant mantas can aggregate in large numbers to feed, mate or clean. The giant manta ray has a widespread distribution along the coast of Australia and is also known to seasonally migrate between aggregation sites (Marshall *et al.*, 2018b). Given the species wide-distribution, this species is unlikely to be encountered during the Otway Basin 3D MC MSS but may be present in higher numbers in the coastal region of the EMBA. **Relevant management plan**: No adopted EPBC documented recovery plan for giant manta ray.

Note: EPBC Act Status: V= Vulnerable, CE= Critically Endangered, CD= Conservation Dependent, E=- Endangered, M= Migratory

4.5.3.3.2 Elasmobranch Biologically Important Area

Elasmobranch BIAs of relevance to the OA and EMBA include distribution (distribution, distribution (low density), and known distribution), foraging, and breeding (nursery area) BIAs for white sharks and foraging and migration BIAs for nurse sharks. These BIAs are depicted in **Figure 21**, and further described in **Table 23**.

Table 23 Elasmobranch BIAs of Relevance to the OA and EMBA

Species	BIA	Location	Distance to OA
White shark	Breeding (nursery area)	Corner Inlet	285 km from OA
	Distribution	Between the 60 – 120 m depth contour	Overlaps OA
		Between the 120 – 1,000 m depth contour	Overlaps OA
	Distribution (low density)	Australian waters from Barrow Island/Montebello Islands, Western Australia to Yeppoon/Swains Reef QLD	Overlaps OA
	Foraging	Waters off pinniped colonies throughout the SEMR	15 km from OA
		Waters off pinniped colonies throughout the SWMR	375 km from OA
	Known distribution	Coastal/shelf/upper slope waters out to 1,000 m depth contour	Overlaps OA
Grey nurse shark	Foraging	Off the coast of Eden	650 km from OA
	Migration	Off the coast of Eden	663 km from OA
		From south of Brooms Head to the south of Bermagui	707 km from OA

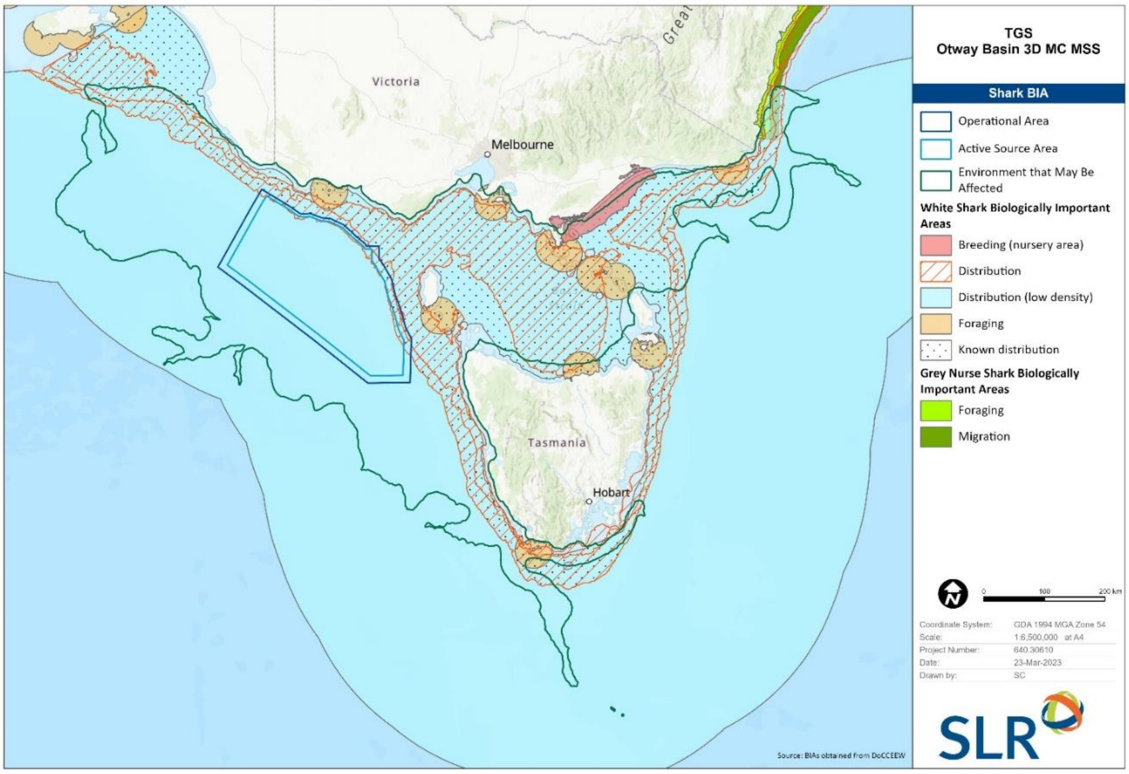

Figure 21 White Shark and Grey Nurse Shark BIAs of Relevance to the OA and EMBA

4.5.4 Cephalopods

All cephalopods consist of a mantle, head, and eight arms (and two long tentacles in the case of some squid). This class of animals includes cuttlefish, squid, octopus, and nautilus. Cephalopods are highly significant ecologically within the marine environment, both as top-level predators and as prey for numerous vertebrates, including fish, seals, cetaceans, and seabirds. Cephalopods, particularly squid, are an important food source for many fish, bird, elasmobranch and marine mammal species that inhabit the OA.

No cephalopod species are included in the EPBC Act List of Threatened Fauna (i.e. identified within the EPBC Act Protected Matters Report); however, according to the Atlas of Living Australia (ALA, 2023), 17 species of cephalopods have been recorded within OA according to Atlas of Living Australia field guide, download generated 28 March 2023 (**Appendix E**). These include various species of squid, octopus and cuttlefish. An additional 92 species of cephalopod were identified within the Atlas of Living Australia report as being present within the wider EMBA.

4.5.5 Marine Reptiles

Results from the EPBC Act Protected Matters Database revealed that there are two endangered and migratory, and one vulnerable and migratory species of marine reptile that may be present within the OA. These are the loggerhead turtle, leatherback turtle, and green turtle. In addition, the hawksbill turtle and flatback turtle may be present within the EMBA based on the EPBC Act Protected Matters Database search results. Both these species are listed vulnerable and migratory. There are no species of sea snake identified as potentially present within the OA or EMBA based on the EPBC Act Protected Matters Database search results.

No breeding behaviours occur within the OA or EMBA, however, foraging, feeding or related behaviour is known to occur within the OA and EMBA for some species. There are no BIAs for marine reptile species of relevance to the OA or EMBA. The Turtle Recovery Plan (Commonwealth of Australia, 2017a) has identified areas as '*habitat critical to the survival of a species*'. There are no such areas identified within the OA or EMBA.

A description of the distribution, preferred habitat and life stages of the identified threatened marine reptile species is provided in **Table 24,** including commentary on their likely presence in the OA and EMBA.

Table 24 EPBC Act List of Threatened and/or Migratory Marine Reptiles Potentially Occurring in the OA and/or EMBA

Common Name(s) Scientific Name	EPBC Act Protection Status	Distribution, Habitat and Life Stages	Records in OA/EMBA	Presence Within the OA and EMBA
Loggerhead Turtle *Caretta caretta*	E, M	Has a distribution throughout tropical, sub-tropical, and temperate waters (Bolten and Witherington, 2003). It is estimated that approximately 2 – 4% of the total global population of loggerhead turtles occurs in Australia, with the majority occurring in eastern and western Australia (DoCCEEW, 2023); In Australia, this species occurs in the waters of coral and rocky reefs, seagrass beds and muddy bays (Limpus, 1995). Although nesting is concentrated in southern Queensland and from Shark Bay to the North West Cape in Western Australia, foraging areas are widely distributed, with females tagged at the south-east Queensland nesting areas recorded in waters off Indonesia, Papua New Guinea, Solomon Islands, New Caledonia, Northern Territory, Queensland, and NSW (Limpus, 2008); Large immature and adult loggerhead turtles feed in a wide range of tidal and subtidal habitats including coral and rocky reefs, sea grass meadows, and soft-bottomed sand or mud areas (Limpus, 2008). Adults feed mainly on hard-bodied, slow-moving invertebrates including molluscs and small crabs (Limpus, 2008); Loggerheads nest of sandy beaches. Hatchlings disperse and spend up to 15 years at sea (Bjorndal *et al*., 2000) where they forage in the top 5 m of the water column (Spotila, 2004). Breeding adults then develop site fidelity to both benthic foraging (out to depths of 55 m, Plotkin *et al*., 1993) and nesting locations (Limpus, 2008); Loggerhead turtles have been recorded infrequently in TAS, VIC and South Australia (Limpus, 2008), including at Mallacoota, VIC, 620 km north-east of the OA (Robertson and Coventry, 2019), and in South Australia including northern Spencer Gulf waters and north-west of Kangaroo Island, over 385 km north-west of the OA (DoCCEEW, 2023).	OA and EMBA	Species LIKELY to occur in OA and KNOWN to occur in EMBA. Foraging, feeding or related behaviour KNOWN to occur within OA and EMBA
Leatherback Turtle, Leathery Turtle, *Dermochelys coriacea*	E, M	Found globally in tropical and temperate oceans (Behler *et al*., 1996). Leatherback turtles are highly pelagic and are known to occur in all waters around Australia (Robins *et al*., 2002); There are no major breeding concentrations of leatherback turtles recorded in Australia, however, low density nesting has been recorded at a limited number of sites in the north and east of Australia, including Wreck Rock Beaches and Rules Beach, southern Queensland, and Coburg Peninsula and Arnhem Land, Northern Territory (Limpus, 2009). Coarse sandy beaches are preferred for nesting (Limpus *et al*., 1984);	OA and EMBA	Species or species habitat KNOWN to occur within OA. Foraging, feeding or related behaviour KNOWN to occur in EMBA.

Common Name(s) Scientific Name	EPBC Act Protection Status	Distribution, Habitat and Life Stages	Records in OA/EMBA	Presence Within the OA and EMBA
		Forages year round over the Australian continental shelf pelagic habitat, but mostly in the south half of Australia (Hamann *et al.*, 2006). A foraging preference for steep bathymetry and converging currents is possible (Houghton *et al*., 2006). Dives to over 1,000 m have been recorded (Houghton *et al*., 2008). Adults feed mainly on pelagic soft-bodied creatures such as jellyfish and tunicates (Bone, 1998). The appearance of leatherback turtles in cool temperate waters is thought to be driven by the seasonal occurrence of large planktonic animals, including jellyfish (Hamann *et al.*, 2006). During times of upwelling, individuals can be regularly seen in southern Australian waters where currents converge with steep bathymetric contours, feeding at all levels of the water column from the surface to the bottom (Hamann *et al*., 2006; Limpus, 2006; Prince, 2004); Leatherback turtles are regularly seen in TAS and VIC during the summer months, particularly in the western and eastern Bass Strait (**Figure 22**); however, records of this species in VIC have decline in recent years, with only seven records between 2012 and 2017 (SWIFT, 2021a); Breeding females can lay up to five times over the nesting period (Spotila *et al*., 1996), but only nest every 2-3 years. Hatchlings disperse widely, but juvenile movements unknown (Lutz and Musick, 1996). Adults make large scale migrations to foraging areas in temperate seas (Benson *et al*., 2007).		
Green Turtle *Chelonia mydas*	V, M	Green turtles are distributed in subtropical and tropical waters of the northern and southern hemispheres (Prince, 1994). The green turtle is the most widespread and abundant turtle species in Australian waters (Limpus, 2002); Major breeding sites for green turtles occur on the north-west, northern and north-east coasts of Australia (Limpus, 2009). Females remain within 5 – 10 km of their nesting beach during the inter-nesting period (Pendoley, 2005). Immature and adult green turtles forage year-round in tidal and sub-tidal habitats including coral and rocky reefs, sea grass meadows and algal turfs on sand and mud flats (Limpus, 2009b). Most green turtles migrate across distances less than 1,000 km, following no given paths. However, in 2015, a green turtle was found on the beach at Yambuk, VIC, approximately 55 km north-west of the OA (McNeil, 2015).	OA and EMBA	Species of species habitat MAY occur within OA. Foraging, feeding or related behaviour KNOWN to occur within EMBA.
Flatback Turtle *Natator depressus*	V, M	Nesting for the entire species is restricted to the northern half of Australia where four breeding populations are recognised – eastern QL, Torres Strait and Gulf of Carpentaria, NT and WA (Limpus, 2007); Flatback turtles last a post-hatching dispersal phase (Walker and Parmenter, 1990) and instead have been reported to stay in coastal waters near breeding beaches.	EMBA	Species or species habitat KNOWN to occur in EMBA.

Common Name(s) Scientific Name	EPBC Act Protection Status	Distribution, Habitat and Life Stages	Records in OA/EMBA	Presence Within the OA and EMBA
		Distribution modelling of flatback turtles indicated a preference for foraging and transiting in clear waters, 60 – 90 m deep, and in association with complex, benthic geomorphology (banks, shoals, terraces, deep holes and valleys) thought to support a high abundance of sessile invertebrates, the likely targets of their foraging (Thums *et al*., 2017).		
Hawksbill Turtle *Eretmochelys imbricata*	V, M	Hawksbill turtles are found in tropical, sub-tropical and temperate waters around the world (DoCCEEW, 2023). Australia supports two genetically distinct populations: 1) on the Northwest Shelf of Western Australia and 2) comprised of Great Barrier Reef, Torres Strait and Arnhem Land. These populations represent two of the five most significant breeding populations globally (see Hoenner *et al*., 2016); In Australia, hawksbill turtles are omnivorous, and consume a variety of animals and plants including sponges, hydroids, cephalopods, gastropods, cnidarians, seagrass and algae (Whiting, 2000).	EMBA	Foraging, feeding or related behaviour KNOWN to occur within EMBA.

Note: EPBC Act Status: E= Endangered V= Vulnerable, M= Migratory

Figure 22 Distribution of Leatherback Turtle Foraging Records in Australia

4.5.6 Marine Mammals

The EPBC Act Protected Matters Report, revealed 34 species of marine mammal (31 cetaceans and three pinnipeds) as having a potential presence within the OA, with four additional species also having a potential presence within the wider EMBA (three cetaceans and one pinniped). These species are listed in **Table 25** along with the 'presence ranking' (as assigned by the Protected Matters Database for both the OA and EMBA), their threat category and migratory status under the EPBC Act. Given the pelagic nature of the OA and parts of the EMBA, several of these species are migratory and are characterised as having large oceanic distributions that are influenced by spatial and temporal variances between feeding and breeding grounds.

There are several BIAs for marine mammals in the vicinity of the OA and EMBA as follows:

- The OA overlaps with pygmy blue whale BIAs for foraging as illustrated in **Figure 23.** These BIAs identify foraging areas of 'high annual use', 'known foraging areas' and 'possible foraging areas'. It is also noteworthy that the remainder of the OA has also recently been nominated as biologically important habitat;
- The OA overlaps with the southern right whale 'known core range' BIA as illustrated in **Figure 24**. In addition, an 'aggregation' BIA and 'migration/resting on migration' BIA also lie inshore of the OA. The boundary of the aggregation BIA occurs 14 km north of the OA. It is noteworthy that the SRW BIAs are currently being reviewed and that updated BIAs are expected to be published before the end of 2023. The Draft National Recovery Plan for the Southern Right Whale (CoA, 2022) includes indicative revised BIAs, but these are subject to change until finalised. For this reason, content of the EP is underpinned by the existing BIAs (as illustrated in **Figure 24**); however, TGS is committed to utilising whichever version of the BIAs is current at the time of survey acquisition and is watching this space carefully;
- A foraging BIA for humpback whales is located within the EMBA, approximately 640 km northeast of the OA (**Figure 25**);
- A foraging BIA for sperm whales is located within the EMBA, approximately 326 km northwest of the OA (**Figure 25**); and

- Two foraging BIAs for Australian sea lions are located within the EMBA, a foraging BIA (male) is located approximately 97 km northwest of the OA and foraging BIA (male and female) is located approximately 312 km northwest of the OA (**Figure 26**).

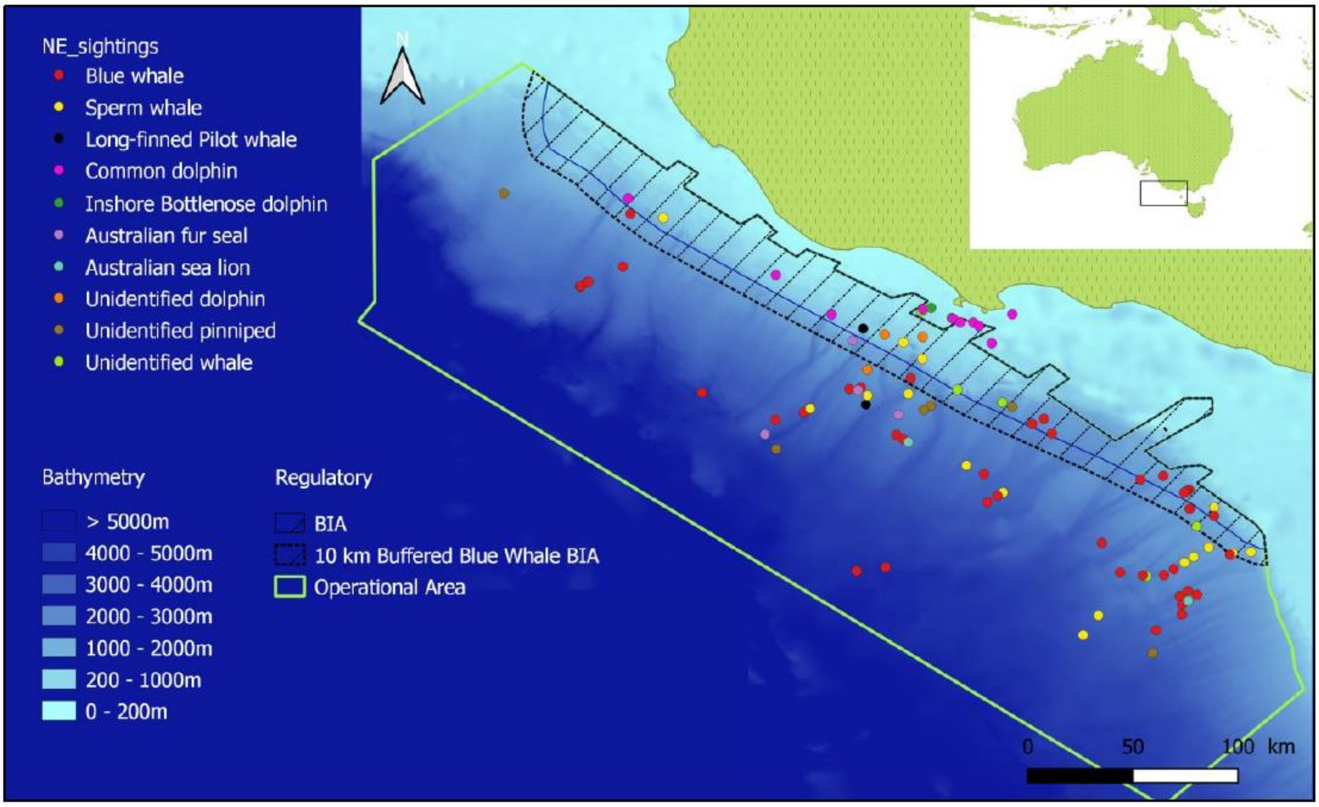
In January to April 2020, Schlumberger Australia Pty Limited (**SLB**) acquired the Otway Basin 2DMC MSS over a similar area to the OA for the Otway Basin 3D MC MSS. The marine mammal detections from this survey are illustrated in **Figure 27** and provide some additional context as to the species that the survey vessels may encounter within the OA during the Otway Basin 3D MC MSS.

Ecological summaries for marine mammal species 'known' or 'likely' to be present in the OA and EMBA are provided in the following subsections, along with those additional species that were detected during the Otway Basin 2DMC MSS.



Source: Seiche Environmental 2020

Figure 27 Sightings of Marine Mammals During the Otway Basin 2DMC MSS

4.5.6.1 Cetaceans – Baleen Whales

Baleen whale species are typically migratory between summer feeding areas and winter breeding areas; hence they have strong seasonal variations in distribution. **Table 26** provides a summary of the expected timing of baleen whale presence in and around the OA.

Table 26 Predicted Timing of Baleen Whale Presence within Operational Area

Species	January	February	March	April	May	June	July	August	September	October	November	December

Southern right whale												
Humpback whale												
Fin whale												
Sei whale												
Minke whale												
Pygmy right whale												

Key:			
Breeding/calving		Peak breeding/calving	
Presence during migrations/movements		Resident population, or consistent presence of transients	
Feeding		Peak feeding	
Most likely time of presence with unspecified activity – most likely feeding			

4.5.6.1.1 Blue/Pygmy Blue Whale

Blue whales (*Balaenoptera musculus*) are widely distributed throughout the world's oceans and comprise two recognised sub-species in the Southern hemisphere: the Antarctic blue whale (*Balaenoptera musculus intermedia*) and the pygmy blue whale (**PBW**) (*Balaenoptera musculus brevicauda*). These two subspecies are difficult to distinguish without the use of genetic techniques, but differ in morphology, distribution, and vocal behaviour. Following an analysis of acoustic detections, and stranding, sighting and historical catch records, Branch *et al*. (2007) concluded that the majority of blue whales in the Australian region are PBW, but that a few Antarctic blue whales (typically found in waters south of 60° S) may migrate to Australia in the austral winter; however, the movement of Antarctic blue whales is poorly understood (CoA, 2015a).

In Australasian waters, the PBW is generally separated into two subpopulations: Eastern Indian Ocean PBWs and New Zealand PBWs (CoA, 2015a). Blue whales are listed as Endangered under the IUCN Red List, and in Australia they are listed as Endangered and Migratory under the EPBC Act 1999. Sightings of blue whales during the Otway Basin 2DMC MSS in 2020 are shown in **Figure 27**.

PBWs have been recorded in waters off all Australian states and the Northern Territory (DEH, 2005; Woinarski *et al.,* 2014). Blue whales are believed to calve in tropical waters in winter, and evidence suggests that the breeding ground for PBWs occurs in Indonesian waters, including Banda Sea, Molucca Sea, Timor Sea and Savu Sea (Gales *et al*., 2010; Thums *et al.,* 2021; Branch *et al.,* 2007; Double *et al.,* 2014; Möller *et al.,* 2020). Sexual maturity of pygmy blue whales is reached at approximately 10 years of age, and adult females calve every two to three years (CoA, 2015). Migration paths are widespread; however, the migratory route of pygmy blue whales off WA enroute to the breeding grounds occurs mostly over continental slope habitat, but the use of continental shelf habitat is more typical of PBW movements off South Australia (Thums *et al*., 2021).

Using data from both satellite tagging studies (2009 – 2021, a total of 22 tagged whales) and acoustic monitoring studies (2006 – 2019), the three most important feeding grounds in Western Australia for PBWs have recently been confirmed by Thums *et al*. (2021) as being 1) the Perth Canyon and vicinity, 2) the shelf edge off Geraldton, and 3) the shelf edge from Ningaloo Reef to Rowley Shoals. Important feeding grounds off the south coast of Australia include Duntroon sub-basin, South Australia; and at the Bonney Upwelling and adjacent waters off South Australia and VIA (Gill, 2002). Photo identification (Garcia-Rojas *et al*., 2018) and genetic evidence (Attard *et al*., 2010) suggests that whales utilising these feeding grounds are from the same population (Attard *et al*., 2010). Historical catch data and limited satellite tagging data also suggest that the northern boundary of the Southern Ocean, known as the Southern Tropical Convergence (**STC**), also constitutes feeding habitat for PBWs, although it is more likely to be a broad, ephemeral feeding site than a focused hotspot (CoA, 2015a; Garcia-Rojas *et al*., 2018). Pygmy blue whales feed on krill and depend on areas of high krill density to meet their high calorific requirements.

The Bonney Upwelling feeding aggregation lies within the boundaries of the OA and PBW feed here seasonally (Gill *et al.,* 2011). For this reason, the upwelling has been identified as a BIA for blue whales (Conservation Values Atlas, 2023). The Bonney upwelling is the largest and most unpredictable of upwellings in south-eastern Australia and extends west from Cape Nelson. It is part of a regional upwelling system with an alongshore extent of ~800 km from the Bass Strait to the eastern GAB upwelling and Kangaroo Island canyons (see **Section 4.4.3.2** for further details).

Use of the Bonney Upwelling by PBW was first noted by Gill (2002) who identified localised aggregations of blue whales feeding on coastal krill in southern Australian coastal waters from December to May, and a noticeable absence of blue whales from the area in winter and spring. Branch *et al.* (2007) analysed historic acoustic detections (see **Figure 28**) and found a peak in call rate of pygmy blue whales within the Australian region from February to May, and a limited number of Antarctic blue whale calls from May to October.

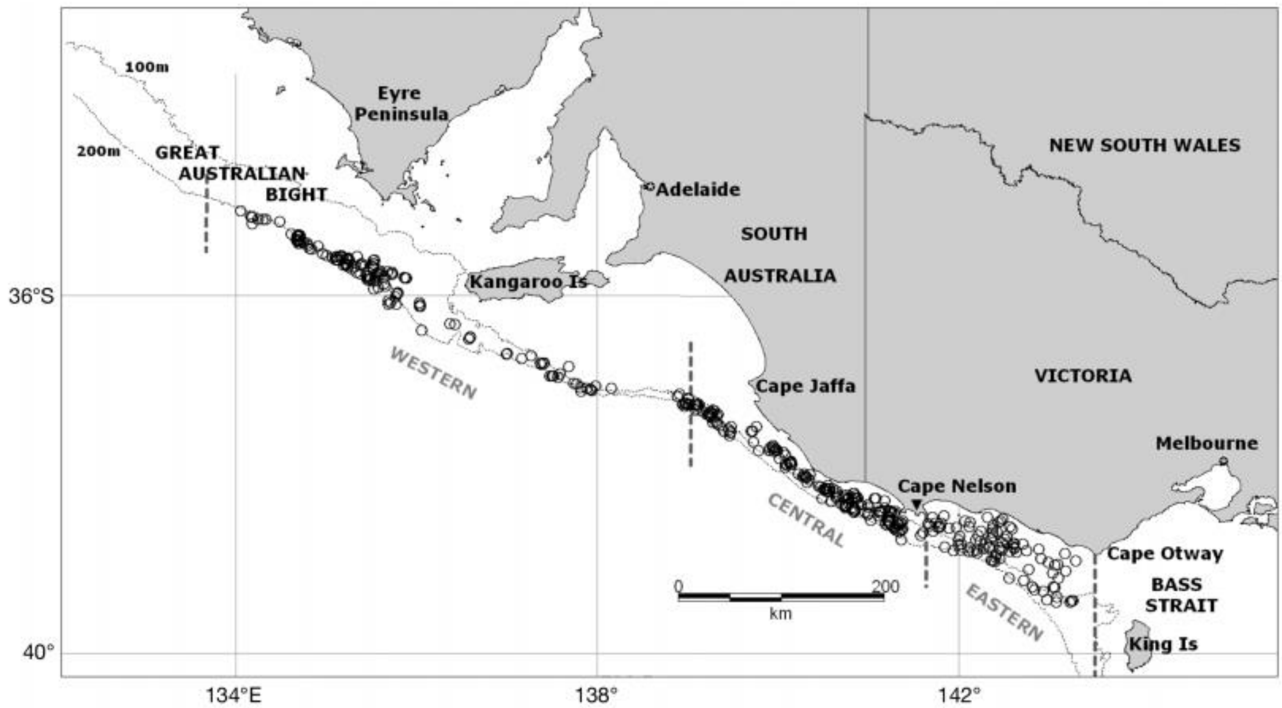
Figure 28 Historic Catch (x), Sighting (o), Stranding (Δ), Acoustic Recordings (▫) and Discovery Mark (∇) Data of Pygmy Blue Whales

Between 2002 and 2007, Gill *et al*. (2011) undertook aerial surveys and plotted the distribution of blue whale sightings (**Figure 29**) to establish links between feeding PBWs and the cold water, nutrient-rich regional upwellings. **Figure 29** is split into the western, central, and eastern zones, with the OA corresponding to the eastern zone and the eastern section of the central zone. Within the upwelling system, the fine scale distribution of blue whales varied according to the local prevalence of krill, but in general foraging occurred in the west of the system early in the upwelling season, spreading eastward until April, then returning towards the west prior to departure for winter grounds in April/May (Gill *et al.,* 2011). The aerial survey data suggests that low densities of PBWs moved eastward in November and December, with PBWs restricted largely to the western and central zones. PBWs moved into the eastern zone from December onward, with animals widely distributed throughout the central and eastern zones from January to April. In the eastern zone abundances peaked in February. Most animals departed from the feeding ground by late April (Gill *et al*., 2011). Over the course of the foraging season, the central zone was the most consistently utilised (Gill *et al.,* 2011). As there was no visible krill at the surface of most sightings (52%), the blue whales sighted in this study were either in transit or feeding deeper in the water column (Gill *et al.,* 2011). More recent unpublished information suggests that in some years reasonable numbers of blue whales can be present in and around the OA as early as November and December (P. Gill pers comm.), highlighting the interannual variability in the feeding season.



Source: Gill *et al*., 2011

Figure 29 Distribution of Blue Whale Sightings, 2002 – 2007

Similar patterns have also been observed from subsequent aerial surveys conducted after 2007 and until 2013, although noting survey effort was relatively low during the period 2008 - 2011 (Gill *et al*., 2015). Jolliffe *et al*., (2021) found that peaks in PBW vocal activity off Portland occurred from January through to April, thereby supporting findings that PBWs remain in the Bonney Upwelling region for several months, likely utilising the central and eastern zones during this period.

PBWs were observed aggregating in a relatively narrow band around a mean depth of 86 m to the west of Portland along or near surface temperature fronts (where temperature may vary by up to 5°C). This aggregation point was associated with elevated levels of chlorophyll *a*, which occurs downstream from upwelling centres and attracts swarms of the krill *Nyctiphanes australis* (Gill *et al*., 2011). Tagged whales have also been shown to spend time in secondary upwelling areas such as around Kangaroo Island (Möller *et al.,* 2020). Morrice *et al*. (2004) reported numbers of PBWs were found feeding on abundant krill surface swarms along the 200 m shelf break to the west and south of Kangaroo Island in December 2003.

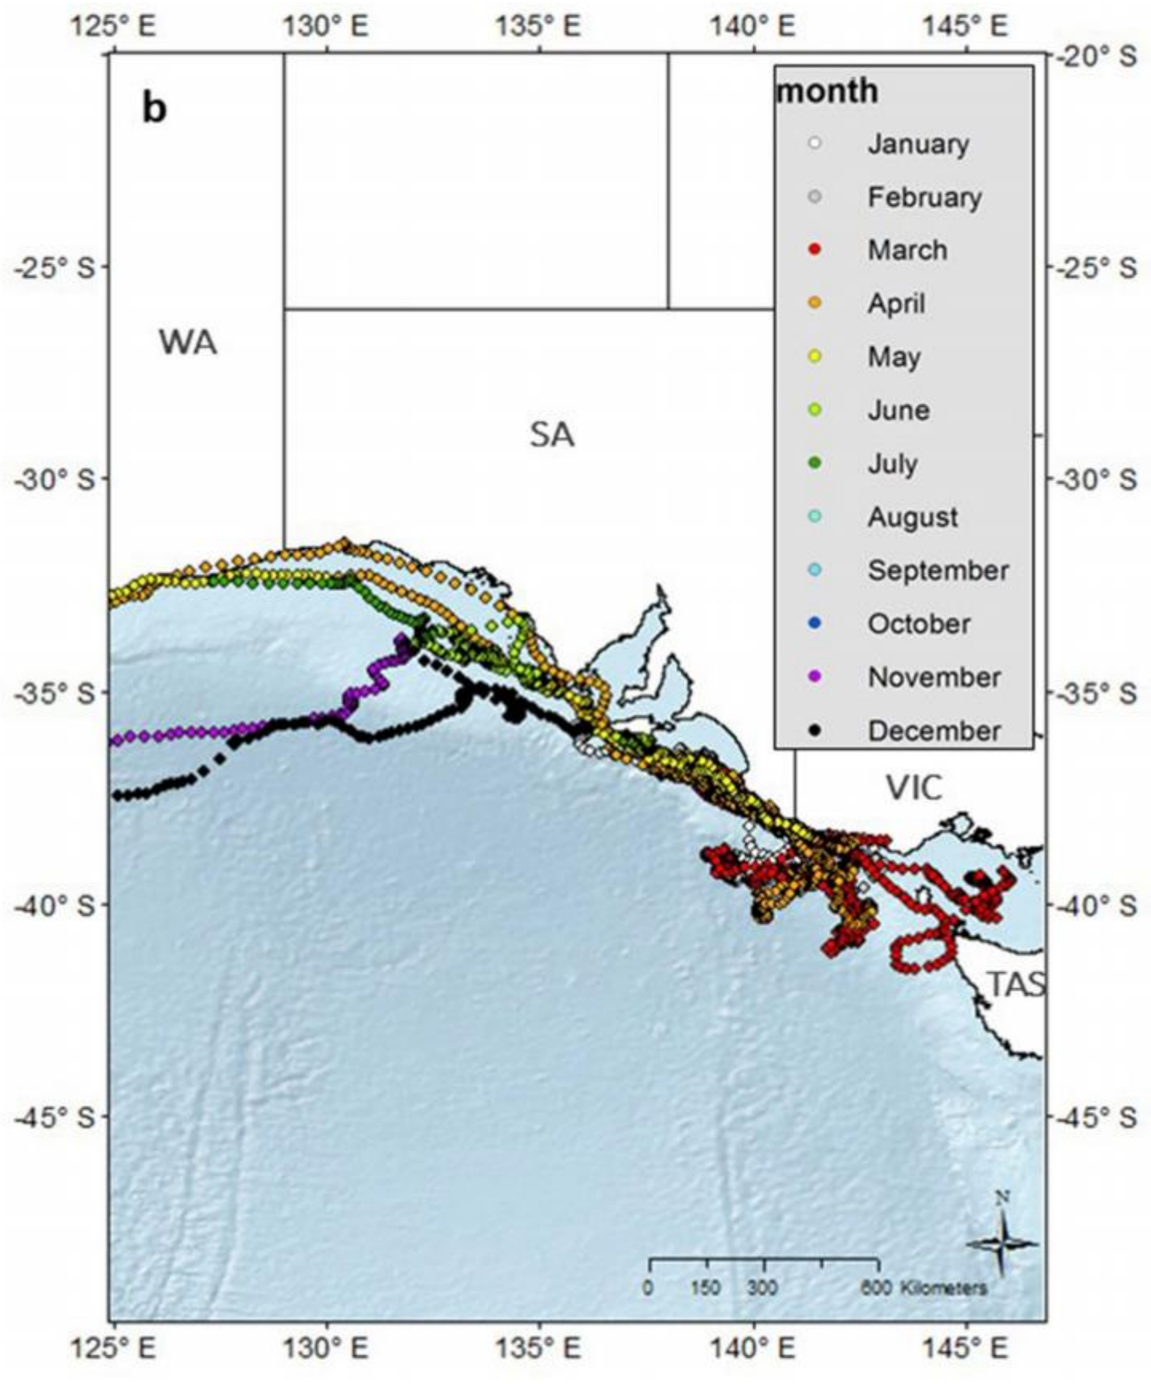
A review of the 2002 – 2007 aerial survey data found 80% of PBWs were encountered at water depths between 50 – 150 m and 93% of sightings occurred in depths <200 m in the eastern and central zones, with 10% of sightings within 5 km of the 200 m isobath (Gill, 2020, as cited in Conoco Phillips, 2021). Encounter rates in the eastern zone peaked in February (9.8 whales/1,000 km) and March (8.8 whales/1,000 km) then declined to approximately 4 whales/1,000 km in April and to a single sighting in May (0.4 whales/1,000 km). No PBWs were encountered in the eastern zone in November, with an encounter rate of 1 whale/1,000 km in December (Gill 2020 as cited in Conoco Phillips 2021). Overall, PBWs were encountered in the central zone at more than twice the rate observed in the eastern zone (11 whales/1,000 km vs 4.8 whales/1,000 km) (Gill 2020 as cited in Conoco Phillips 2021).

Mean group size is typically small; 1.3±0.6 individuals (Gill, 2020). This is consistent with the findings of Branch *et al*. (2007) who reported that 65.2% of blue whale sightings in the Southern Hemisphere and northern Indian Ocean were of a single whale and 24.6% were of a pair, with only rare sightings of groups composed of more than five individuals.

Historical (Mikhalev, 2000; Branch *et al.,* 2007) and more recent (Miller *et al*., 2012; Garcia-Rojas *et al*., 2018; Möller *et al*., 2020) records also show lower numbers of PBWs can be found in deeper waters of the OA and the broader region, including at depths greater than 2,000 m (Miller *et al*., 2012). Satellite tagging evidence that individual blue whales may move between the Bonney Upwelling and the STC feeding grounds further south also suggests that individual whales may make independent foraging choices based on prey availability (Garcia-Rojas *et al*., 2018). Garcia-Rojas *et al*. (2018) tagged four PBWs at Discovery Bay, west of Portland, in April 2005 with three tags transmitting data for 9 – 15 days and one for 17 days. The three shorter duration tags showed the whales remained over the continental shelf until tag transmissions ceased, while the fourth whale tracked due south to the STC after 12 days, with the final received position being south of the OA at 39^{o}57'S, 139^{o}29'E (Garcia-Rojas *et al*., 2018).

Möller *et al*. (2020) satelitte tagged 13 PBWs in the Bonney Upwelling region in January 2015, including 12 unaccompanied adults and one cow-calf pair. Whales were tracked for an average of 116 ± 114 days, ranging from 3 to 282 days (**Figure 30**). After tagging, whales remained in the Bonney Upwelling and broader southern Australian coastal region from at least January to July 2015, for an average of 54.6 ± 29.4 days (range 3 – 107 days) (Möller *et al.*, 2020). Four tagged whales left the Bonney Upwelling region between late April and July, moving in a westward direction while off the southern Australian coast (Möller *et al*., 2020). In November and December 2015 respectively, two tagged whales returned to the region and remained until at least December 2015 and March 2016, spending 69 and 166 days respectively in the region between the two annual feeding seasons.

The continental shelf of the Bonney Upwelling region showed the highest occupancy rate by the whales, consistent with the results by Gill (2011), with whales presumably feeding on *N. australis* (Möller *et al*., 2020). However, a few whales, including the cow-calf pair, were observed to utilise the area over the slope and deep sea, suggesting PBWs may also be feeding in mesopelagic waters and potentially on other krill species associated with deeper waters (Möller *et al*., 2020).



Source: Möller *et al.,* 2020

Figure 30 Satellite tag locations of 13 pygmy blue whales in the Bonney Upwelling region

Blue whales vocalise at a low frequency (average of 0.01 – 0.110 kHz) (McDonald *et al.*, 2001; Miller *et al.*, 2014), meaning that their calls travel hundreds of kilometres underwater. Vocalisations of PBWs off Cape Leeuwin, Western Australia have been characterised as songs of either two or three repeating tonal sounds with harmonics (Gavrilov *et al.,* 2011). The most intense tonal sounds were recorded to have a source level of 179 ±2 dB re 1 µPa @ 1 m. Weaker short-duration calls of impulsive down-swept sounds were estimated to have source levels of 168 – 179 dB re 1 µPa @ 1 m (Gavrilov *et al.,* 2011). Different blue whale/PBW populations have different call characteristics (McCauley *et al*., 2018).

McCauley *et al*. (2018) used passive acoustics to record blue whale calls at fifteen sites around Australia from 2000 – 2017 (**Figure 31**). This study found that East Indian Ocean PBWs were present from north-west Western Australia (site 1) south and east to Bass Strait (site 14); New Zealand PBWs were present from Portland (site 11) east to NSW (site 15); and Antarctic blue whales were present at all sites south of 19^{o}S (sites 2-15). Of particular relevance to the OA is the data collected from the Portland receiver (site 11). **Figure 32** illustrates call rates at site 11 (Portland) for the years over which recordings were made, indicating that in most years whales arrived in the region in February and remained until April – June. With the maximum number of calling animals detected at any one time being two. All three blue whale song types were recorded at the Bass Strait and Portland sites (14 and 11) over April to June 2004, but later years found only the two PBW call types present during these months. Garcia-Rojas *et al*. (2018) suggested PBWs vocalize at higher rates when there are no other callers nearby and/or possibly when traveling alone in the open ocean. Call production may also occur at the expense of foraging, with lower call rates by foraging whales compared with those travelling (Oleson *et al.,* 2007).

Figure 32 Mean number of calling East Indian Ocean Pygmy Blue Whales averaged over 24-hour periods from 2009 – 2016.

Table 27 summarises the information outlined above relating to PBW seasonal use of the upwelling and surrounding waters. Within this table, there is substantial variability in the spatial scale over which the findings are relevant. Where possible, the core feeding season is denoted by a darker grey. From the multiple lines of evidence available PBWs arrive in continental shelf waters of the Bonney Coast to feed around November to December, with peak activity occurring in the vicinity of the OA from January through to April (Gill *et al*., 2011; 2015; Moller *et al.,* 2020; Jolliffe *et al.,* 2021), but with consistent presence expected through until the end of June (McCauley *et al.,* 2018). On this basis, this EP uses the following terminology:

- PBW Foraging Shoulder Season – September to December and July; and
- PBW Peak Foraging Season – January to June (inclusive).

Table 27 Seasonality of Pygmy Blue Whales in the vicinity of the OA

Reference	Nov	Dec	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Notes
Jolliffe *et al.* (2021)													Peaks in PBW vocal activity off Portland occurred from Jan to Apr.
Möller *et al.* (2020)													Satellite tagging data from 13 PBWs in the Bonney Upwelling in January 2015. Remained in the region from Jan to late Apr - Jul, two returned in Nov/Dec.
McCauley *et al.* (2018)													Passive acoustic monitoring off Portland. Most PBWs arrived in the region in Feb, remaining until Apr – Jun.
Gill *et al.* (2011); (2015); and pers comm.													Aerial surveys. Presence possible from Sep, with low densities in Nov and Dec, widely distributed through the central and eastern zones (vicinity of OA, see **Figure 29**) from Jan to Apr. Most departed by late Apr but seen into May.
Branch *et al.* (2007)													Peak in call rates of historic acoustic detections in broad-scale Australian region from Feb to May
Gill (2002)													Localised feeding aggregations in broad-scale southern Australian waters from Dec to May.

The OA overlaps with a number of PBW foraging BIAs (**Figure 23**). The south-east section of the OA partially overlaps with a PBW known foraging area encompassing the north-west part of Bass Strait, from Cape Otway to Port Phillip Heads and to the south of King Island, and a PBW foraging likely area encompassing the majority of the Bass Strait and the coastal waters of TAS. The northern section of the OA overlaps with the PBW Bonney Upwelling foraging BIA (annual high use area) extending between Cape Otway and Robe. Due to the overlap between the OA and these BIAs, the likelihood of encountering PBW during the Otway Basin 3D MC MSS is '**moderate to high**'.

While the majority of blue whales within the OA are likely to be PBW, the presence of Antarctic blue whales cannot be dismissed; however, acoustic data suggest that this species is more likely present in the region over the cooler months and presence is less consistent than that of PBW. On this basis the likelihood of encountering Antarctic blue whales during the Otway Basin 3D MC MSS is considered to be '**low**'.

4.5.6.1.2 Southern Right Whale

Southern right whales (**SRW**) (*Eubalaena australis*) have a circumpolar distribution throughout the Southern Hemisphere between 16°S and 65°S and occur throughout Australia's southern coastline as far north as Sydney on the east coast and Perth on the west coast (CoA, 2012). They migrate annually from summer feeding grounds to warmer, protected waters over the continental shelf during the Austral winter (IWC, 2001). There are three likely foraging areas used by Australian SRWs: south-west of WA, waters of the subtropical front, and Antarctic waters (Childerhouse *et al*., 2010; Mackey *et al*., 2020; Riekkola *et al*., 2021). Evidence suggests that individual preferences for feeding and breeding grounds are culturally inherited through the maternal line (i.e. whales forage and breed at the same grounds as their mother) (Valenzuela *et al*., 2009; Carroll *et al*., 2015; Patenaude *et al*., 2007). Female SRWs typically show very strong site fidelity to calving grounds (Charlton, 2017; Burnell, 2001).

The SRW was depleted to near extinction as a result of whaling activities in the 19th and 20th centuries (Dawbin, 1986; Tormosov *et al*., 1998; Carroll *et al*., 2014), however post whaling SRW numbers are increasing globally, with the population last estimated at 13,600 individuals in 2009 (IWC, 2013). Currently, SRWs are listed as Least Concern under the IUCN Red List, and in Australia they are listed as Endangered and Migratory under the EPBC Act 1999.

In Australia, the SRW is divided into two 'populations' or 'management units': the western population and the eastern population (CoA, 2022). The western and eastern populations are considered genetically distinct from one another (Carroll *et al*., 2011); however, limited movement between the two areas has been recorded (Burnell, 2001; Pirzl *et al*., 2009; Charlton, 2017; Watson *et al*., 2021) and both populations mix when using shared migratory pathways (CoA, 2022). The western population is recognised to occur in Western Australia and South Australia (primarily between Cape Leeuwin and Ceduna), while the eastern population occurs off VIC, TAS, NSW, and QLD (CoA, 2022).

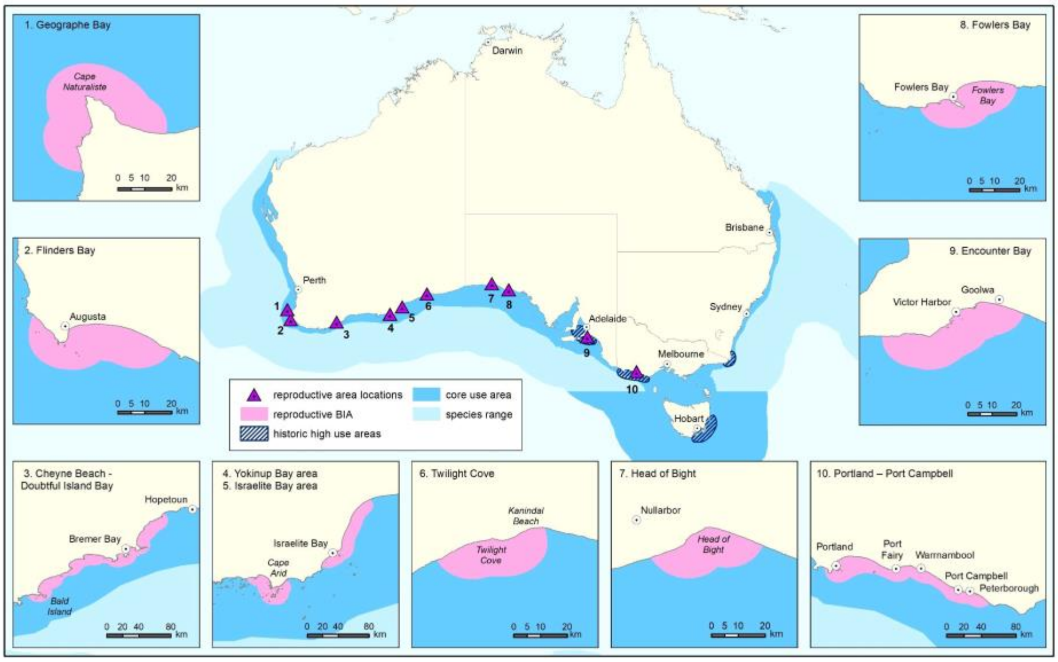
The most recent population estimate of SRW numbers in Australia is approximately 3,500 individuals, comprised of approximately 3,200 individuals in the west and around 270 individuals in the east (Bannister, 2017; Smith *et al*., 2019; Stamation *et al*., 2020). The western population is increasing at a rate of approximately 6% per annum (Smith *et al*., 2020), and the eastern population at a rate of approximately 4.7% per annum (Stamation *et al*., 2020).

SRW coastal calving/nursery grounds occur in shallow sloping sandy bottom bays (Elwen & Best, 2004; Pirzl, 2008) in coastal waters between 16°S and 52°S (IWC, 2010). SRWs visit the sheltered bays off the southern Australian coastline between May and October each year to calve, mate and rest (CoA, 2022). However, occasionally individuals arrive as early as April and depart as late as November (CoA, 2022). In coastal habitats, SRWs usually occur within 1 km of the shore where they aggregate in discrete areas at elevated densities (**Figure 33,** CoA, 2012; CoA, 2022). There is some spatial segregation of cohorts with mother-calf pairs typically occurring in shallower more sheltered water than unaccompanied adults; noting that as calves grow the range of mother-calf pairs increases (CoA, 2022). Depth appears to be the most influential determinant for habitat selection, with whales preferentially occupying water depths less than 10 m at coastal aggregation areas (Pirzl, 2008).

Peak abundance of SRW in coastal aggregation areas occurs mid-July to end-August (Charlton *et al*., 2019). Pregnant females generally arrive in June and depart with calves in September (CoA, 2022). Mother-calf pairs remain at the calving grounds for 2 – 3 months (Burnell and Bryden, 1997). The presence of unaccompanied whales is characterised by a higher degree of temporal variability (Burnell and Bryden, 1997; Charlton *et al*., 2019). Movement of calving and non-calving adults has been recorded across broad distances both within and between seasons (Pirzl *et al*., 2009; Watson *et al*., 2021). There is no evidence that mothers are feeding during the initial months of lactation at calving/nursery grounds (Miller *et al*., 2012). This species typically has a three-year calving cycle; a resting year with no migration follows the year of calving, then a mating year (Brandão *et al*., 2011). Mating is thought to occur away from the calving grounds, and potentially at feeding grounds (Watson *et al*., 2021). Calving interval occasionally extends to five years (CoA, 2022), and at the largest calving area in South Australia (the Head of the Bight), mean calving interval has increase during the 2015 – 2021 monitoring period from three to four years (Charlton *et al.,* 2022). At this same location neonatal mortality is estimated to be 3% during the first three months of life (Burnell, 1999).

Ten reproductive areas have been identified across the southern coast of Australia (**Figure 33;** COA, 2022), the largest of these being the Head of Bight in South Australia, and Doubtful Island Bay and Israelite Bay in Western Australia (CoA, 2012). In VIC (and of greatest relevance to the OA), a reproduction area occurs between Portland and Port Campbell (shown as Area 10 on **Figure 33**). Logans Beach, Warrnambool (approximately 59 km north-northeast of the OA) is the largest aggregation to occur in this reproductive area, with 51 individual SRWs sighted at this location between 1995 and 2018, including 15 cow-calf pairs (Watson *et al*., 2021). Other aggregations in this area also occur at Portland, Port Fairy, Port Campbell, and Peterborough located approximately 42 – 64 km from the OA. SRWs consistently use these areas for calving in varying densities (CoA, 2022). SRWs are known to reside in reproductive areas for three to four months (Charlton, 2017).

The draft SRW Recovery Plan (CoA, 2022) states that reproductive areas are "*important for SRW recovery as they contribute to overall population increases in abundance, maintenance of genetic diversity (given site fidelity may lead to small-scale genetic differences) and expanding habitat occupancy*".



NOTE: 'Reproductive BIAs' shown here must be considered as indicative only until the Draft National Recovery Plan for SRW has been finalised.
Source: Commonwealth of Australia, 2022

Figure 33 SRW Reproductive Area Locations

It is noteworthy that the 15 females identified from Logans Beach produced at least 56 calves from 1995 to 2018 (Watson *et al.,* 2021). At this calving ground, an average of 2.6 (± 0.3) calves are born each year and the mean calving interval is 3.5 ± 0.2 years; however, this increased to 3.9 ± 0.2 years between 2007 and 2018, suggesting that some females from the eastern population may be calving less or occasionally calving in other areas (Watson *et al*., 2021). Watson *et al*. (2021) report no significant change in the annual abundance of cow-calf pairs in the south-eastern Australia region in more than three decades; and specifically, there has been no increase in the number of mother-calf pairs at Logans Beach (Stamation *et al*., 2020).

Across VIC, SRW sightings are variable but are primarily recorded from the areas identified in **Figure 33** with whales usually having a short residency period at these locations (SWIFFT, 2023). First sightings at aggregation areas in VIC usually occur in May (54%) and June (42%), with the majority of last sightings in September (50%) and October (38%) (SWIFFT, 2023). Understanding the temporal presence of SRW in and around the OA is critical to assessing the potential effects of the Otway Basin 3D MC MSS on this species. To this end, the available SRW data for the southwest VIC coast (as collated in the Victorian Biodiversity Atlas) over the past 10 years is summarised in **Table 28**.

Table 28 Dates and Locations of First and Last SRW Sightings for Southwest VIC (west of Melbourne)

Year	First Sighting of Season		Last Sighting of Season	
	Date	Location	Date	Location
2021	30 May	Port Campbell	29 Sep	Apollo Bay
2020	16 Jun	Portland	16 Aug	Portland
2019	13 Apr	Logans Beach	3 Nov	Warnambool
2018	19 May	Portland	25 Sep	Logans Beach
2017	7 May	Logans Beach	22 Oct	Cape Nelson
2016	21 May	Apollo Bay	29 Aug	Portland
2015	31 May	Logans Beach	11 Sep	Logans Beach
2014	14 Apr	Logans Beach	12 Oct	Logans Beach
2013	30 Mar	Warnambool	5 Oct	Logans Beach

Source: https://vba.biodiversity.vic.gov.au/vba/index.jsp

These records suggest that SRW presence in the SRW Aggregation BIA should be expected from May to September (core aggregation months), with whales sometimes arriving in April and remaining through until October.

Gill *et al*. (2015) carried out aerial surveys of cetaceans from western Bass Strait to the eastern GAB between 2002 and 2013. Although effort within this survey was biased towards coverage of the Bonney Upwelling and the corresponding presence of PBWs, survey effort occurred within all months. Throughout the study, a total of 12 sightings making up 52 individual SRWs were noted, with all sightings made between June and September. No SRWs were observed between October and May. Encounter data per 1,000 km of survey distance for the period through which SRWs were observed is presented in **Table 29**. This data supports the finding that the core aggregation months in the vicinity of the OA occur from May to September. Gill *et al*. (2015) also reported that SRWs occurred in shallower waters than all other cetacean groups, with all sightings of this species occurring in the depth band of 0 – 100 m. SRW mother-calf pairs and mating behaviours were regularly observed through winter months (Gill *et al*., 2015).

Table 29 SRW Encounter Data by Month, Pooled for all Years (2002 – 2013)

Number of whales sighted per 1000 km of survey distance	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
	0	0	0	0	0	0.8	3.1	6.8	8.8	0	0	0

Source Gill et al., 2015

Little is known about the movement of SRWs between coastal reproductive areas and offshore waters. Historical evidence suggests that SRWs move from the southern feeding grounds towards the east coast of TAS early in the season (April), followed by westward movement through Bass Strait and across the GAB (Dawbin, 1986), with the majority of whales thought to return southwards from WA towards feeding grounds at the end of the season (October to December) (IWC, 2001). Photo identification studies support a seasonal westward movement in coastal habitat and highlight the importance of coastal connecting habitat (DSEWPC, 2012; Watson *et al*., 2021), but direct southerly approaches and departures from the VIC coast cannot be dismissed. However, it is generally accepted that the migration pattern of this species is typified by counter-clockwise movement, whereby animals arrive in the east of Australia in May – July, peak in coastal aggregation areas during July/August and then migrate west along the coast before migrating back to southern feeding grounds in Sept/Oct (Burnell, 2001).

A satellite tagging study conducted from the Head of Bight area (Area 8, **Figure 33**) provided information on the movement of SRWs at the end of the season, with two cow-calf pairs migrating directly south, and one moving west past Albany (Mackay *et al*., 2015). Burnell (2001) reported a within season movement of a single SRW first sighted at Portland on 22 July 1994, and 49 days later sighted at the Head of Bight on 9 September 1994, having travelled a distance of 1,297 km north-west with an average speed of 1.1 km/hr, and further supporting westward movement along the southern Australian coast. Similarly, of seven within-season movements of SRWs between south-eastern and south-western Australia, five were in a westerly direction (Watson *et al*., 2021). The longest within-season movement detected was ~1,600 km by a female moving between Cape Nelson, VIC and Head of Bight, South Australia (Watson *et al*., 2021).

SRWs produce low-frequency social sounds including stereotyped upcalls used as contact calls and other tonal sounds for mate attraction (Parks and Tyack, 2005). Such vocalisations range in frequency from 50 – 600 Hz (Parks *et al*., 2007; 2011) at sound levels from 172 – 187 dB re 1 µPa @1 m (as referenced in Erbe, 2002). Mother-calf pairs produce infrequent low amplitude vocalisations, the nature of these calls are thought to decrease the risk of predation by minimising signals which may be detected by potential predators (Nielsen *et al*., 2019, Parks *et al.,* 2019, Zeh *et al.,* 2022).

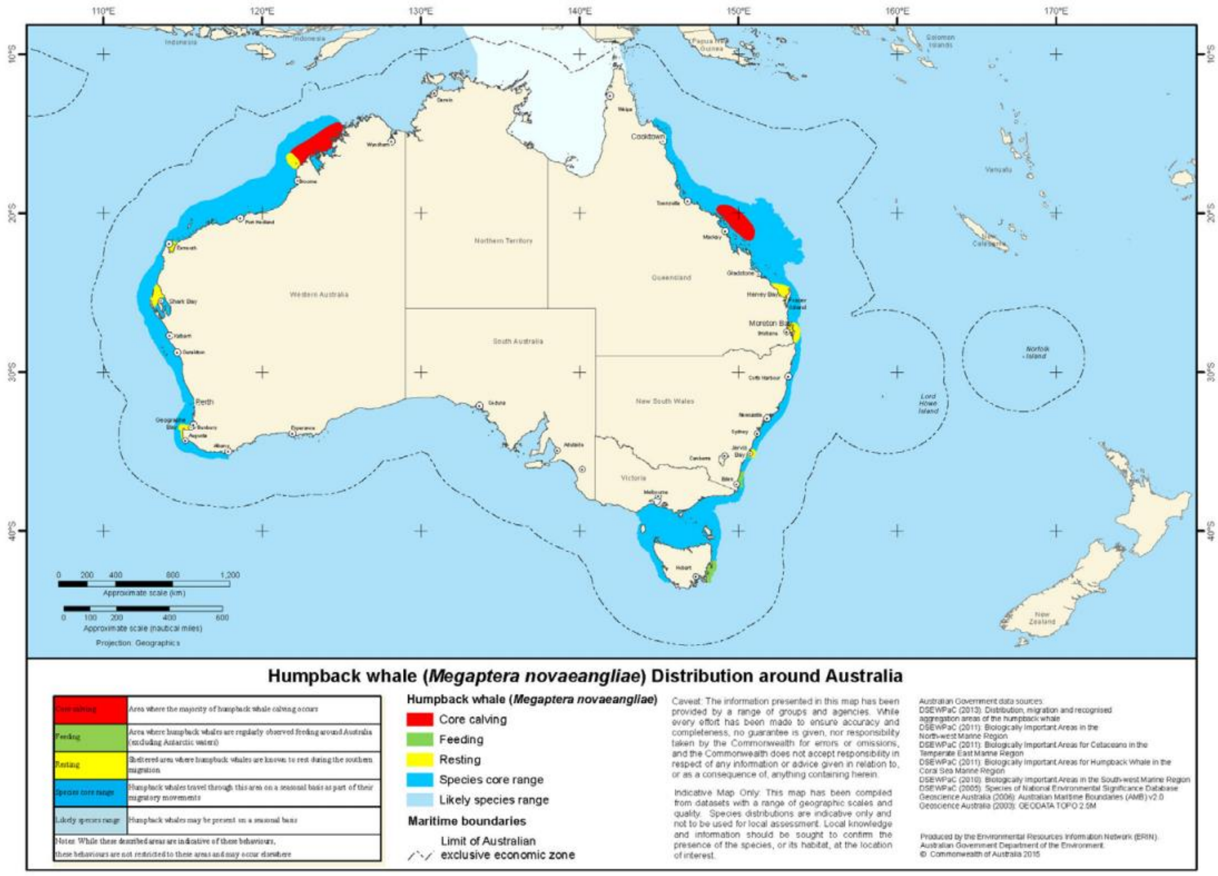
The OA overlaps with the SRW 'known core range' BIA as illustrated in **Figure 24**. In addition, an 'aggregation' BIA (Bridgewater Bay, Portland to east of Logan's beach, Warrnambool) occurs 14 km north of the OA, and the north-western portion of the OA is located approximately 32 km from the SRW migration and resting on migration BIA.

The likelihood of encountering SRWs during the Otway Basin 3D MC MSS has been assessed to be '**moderate**' as there is the potential for some spatial and temporal overlap between the presence of this species and the Otway Basin 3D MC MSS, particularly in the inshore portion of the OA and given that the survey could be underway by the end of the breeding season (September/October).

4.5.6.1.3 Humpback Whale

The humpback whale (*Megaptera novaeangliae*) is widely distributed in all oceans. Humpback whales undertake the longest migration of any mammal (Jackson *et al.*, 2014). They are seasonal migrants that move between low latitude winter breeding grounds and mid- to high-latitude productive summer feeding grounds (Pomilla and Rosenbaum, 2005; Robbins *et al*., 2011; Chittleborough, 1965; Dawbin, 1966). Humpback whales were hunted to near extinction in Australian waters by the commercial whaling industry throughout the 1950s and early 1960s (Smith *et al*., 2012). Following the cessation of commercial whaling, populations of humpbacks have steadily increased. In Australia, humpback whales are divided into east coast and west coast populations. It is estimated that there are around 35,000 individuals in the west coast population, and around 25,000 individuals in the east coast population. The rate of humpback whale population increase on the east coast of Australia is estimated at around 10 - 11.5% per year (Noad *et al*., 2008), and 9% (Bjeder *et al*., 2016) on the west coast. Humpback whales are currently listed as Least Concern under the IUCN Red List, and in Australia were removed from the EPBC Act 1999 threatened species list in 2022 (DoCCEEW, 2023).

The majority of humpback whales in Australian waters migrate north from May to August, and back towards the Southern Ocean from September to November. West coast humpbacks migrate up the west coast of Australia, as far north as Broome and Kimberley, while east coast humpbacks diverge around TAS and move up the east coast of Australia to Hervey Bay, Queensland (**Figure 34**). Breeding and calving occurs during winter months (June – September) in water depths of 30 – 58 m (Smith *et al*., 2012). Although humpbacks do utilise deep oceanic waters during portions of their migration, off Australia they typically move within the continental shelf boundary or 200 m bathymetry (Jenner *et al*., 2001), within 50 km of the coast (DoCCEEW, 2023).

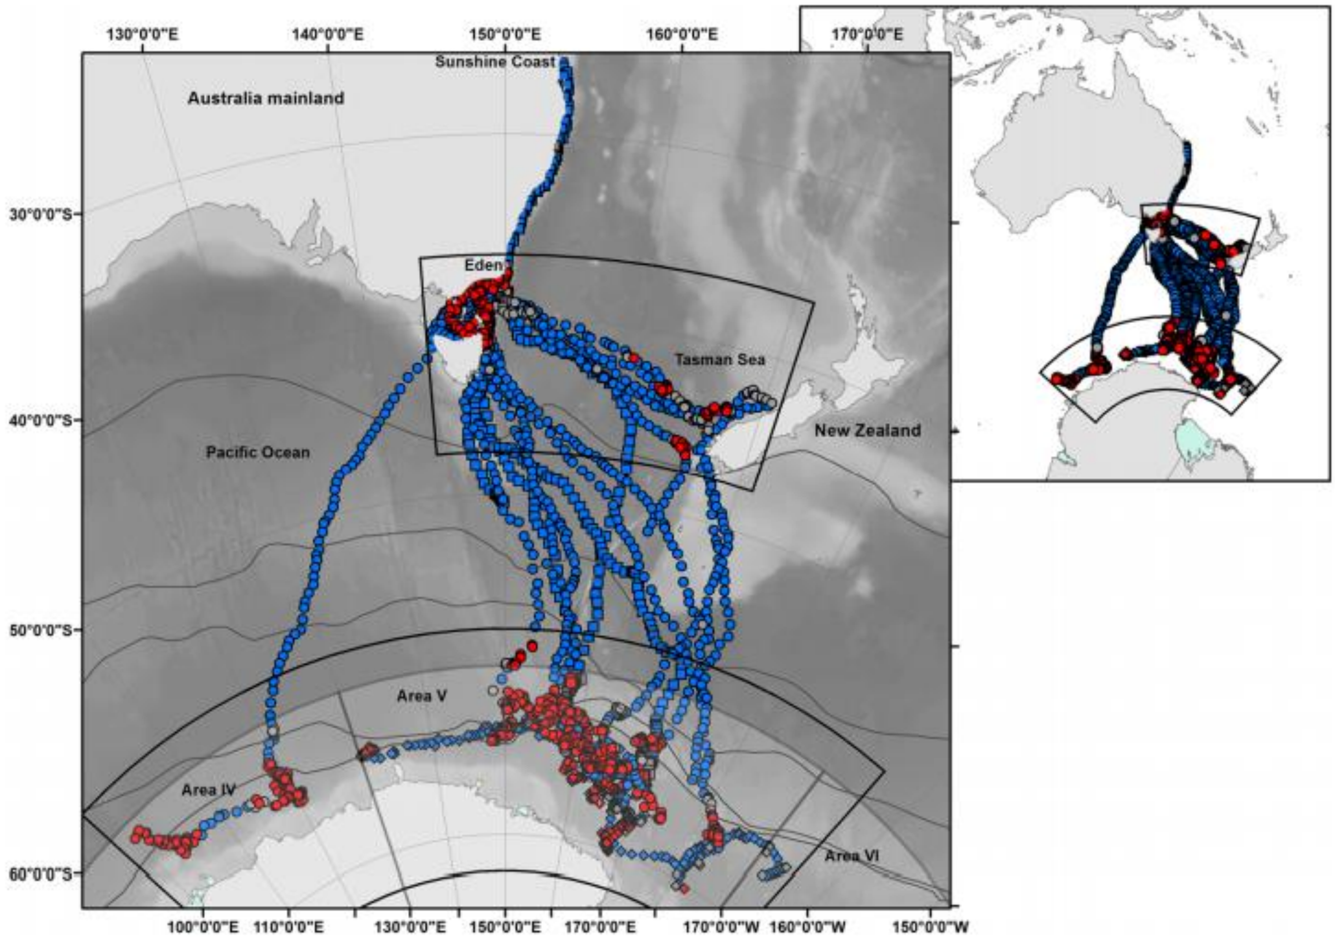


Source: DoCCEEW, 2023

Figure 34 Humpback Whale Distribution around Australia

Humpback whales pass through VIC in the highest numbers during June and July, with some whales returning enroute south in September to October (SWIFFT, 2021c). In VIC, there are reports of humpback whale sightings in all months except February (Warneke, 1995). In South Australia, humpback whales have been observed during all months, and it is thought they are from both the east and west coast populations (DoCCEEW, 2023).

Andrews-Goff *et al.* (2018) used satellite tagging technology to track the southern migration of humpback whales along three migratory trajectories off Australia's east coast (**Figure 35**). The 21 whales tagged off the eastern Australian coast migrated south along the coastline and across the eastern entrance to Bass Strait in October. Twelve whales were also tracked in November moving south along the east coast of TAS, while one whale utilised the western coast of TAS where it continued in a southwest direction into the Pacific Ocean before heading towards Antarctic feeding grounds. Seven whales travelled eastwards into the Tasman Sea, with three animals spending time off the southwest coast of New Zealand (Andrews-Goff *et al.,* 2018). All migrating humpbacks with transmitting tags had arrived at Antarctic feeding grounds by January (Andrews-Goff *et al.,* 2018). The tracks recorded by Andrews-Goff *et al.* (2018) agree with those recorded in previous studies such as Gales *et al.* (2009). While on southern migrations off the headlands of the southern coastline of Queensland and NSW, the migratory corridor is narrow, with whales passing within 5 km of land (Noad *et al.,* 2008). Whales on northern migrations tend to use more offshore waters (Noad and Cato, 2001).



Source: Andrews-Goff *et al.* (2018)

Figure 35 Migration Pathways for Humpback Whales Satellite-Tagged off the Eastern Coast of Australia – Dot Colours Show Recorded Behavioural State; Red ('Search'), Blue ('Transit'), Grey ('Uncertain')

Feeding by humpback whales in Australian waters was initially thought to be opportunistic (Stockin and Burgess, 2005); however, recent satellite tracking suggests that humpback whales temporarily suspend migration to forage (Andrews-Goff *et al*., 2018). Recently identified supplemental feeding areas (i.e. those not at Antarctic feeding grounds) have been identified through Bass Strait, along the east coast of Australia, and within the eastern Tasman Sea (e.g. Stockin and Burgess, 2005; Stamation *et al.,* 2007; Andrews-Goff *et al*., 2018). Gill *et al*. (2015) observed a juvenile humpback whale lunge feeding in the Bonney Upwelling; and during late September to early October 2020, humpback whales were observed feeding off Portland (SWIFFT, 2021c).

Both male and female humpbacks produce communication calls, but only males emit the long, loud, and complex 'songs' associated with breeding activities. Dunlop *et al*. (2007) recorded social vocalisations of migrating east Australian humpbacks and recorded frequencies ranging from <30 Hz to 2.5 kHz over 34 different vocalisation types. The source level of singing humpback whales ranges from 123 – 183 dB re 1 µPa @ 1 m (Dunlop *et al.,* 2013). Surface-generated social sounds (e.g. breaches, pectoral slaps, and tail slaps) are also generated by humpback whales and are thought to have a communicative function (Dunlop *et al.,* 2010). These surface-generated sounds have been reported to be in the range of 133 – 171 dB re 1 µPa @1 m (Dunlop *et al.,* 2013).

There are no known BIAs (feeding, calving and resting) or migratory routes for humpback whales within or adjacent to the OA. A foraging BIA is located within the EMBA, approximately 640 km northeast of the OA. However, humpback whales may be encountered throughout the OA during both their north- (June – July) and south-bound (September – October) migrations.

Humpback whales have been assessed to have a '**moderate**' likelihood of occurring within the OA during the Otway Basin 3D MC MSS. The Otway Basin 3D MC MSS will occur temporally and spatially proximate to migratory pathways, particularly during the southward migration period (September to October).

4.5.6.1.4 Fin Whale

Fin whales (*Balaenoptera physalus*) have a global distribution and are found in offshore waters throughout the world (NOAA, 2018). Like other baleen whales, they head to high latitudes (between 50°S and 65°S) to feed over the summer months (Miyashita *et al*., 1995) and move to warmer lower latitude waters during winter to breed. Their migration paths are oceanic, and do not obviously follow coastlines (Bannister *et al.,* 1996). In the Southern hemisphere, fin whales were depleted to just 2% of their population size during the era of widespread commercial whaling (AMMC, 2019). Fin whales are currently listed as Vulnerable under the IUCN Red List, and in Australia they are listed as Vulnerable and Migratory under the EPBC Act 1999.

The distribution of fin whales in Australian waters is mainly known from stranding events and historic whaling records, with one stranding reported in VIC (Larcomb *et al*., 2002) and two strandings reported in South Australia (Bannister *et al*., 1996). Fin whales have been sighted inshore of the Bonney Upwelling in VIC waters during aerial surveys in summer and autumn months (Gill, 2002), between November and May (Gill *et al*., 2015). Within the Bonney Upwelling, fin whales were distributed in shelf waters, in water depths of 162 ± 90 m (sample size seven individuals) (Gill *et al*., 2015). Whales were observed to be feeding, with a fin whale bubble cloud seen near krill (Gill *et al*., 2015). Most fin whale sightings were of adult whales, although a cow-calf pair was sighted on one occasion, suggesting that the region may be used for breeding or rearing young (Gill *et al*., 2015).

Fin whale communication vocalisations have been described as short (<1 second) down-swept tones, between 28 and 15 Hz at source levels of 189 ± 4 dB re 1 µPa @1 m (Širović *et al*., 2007). Underwater acoustic recordings have been collected approximately 50 km south-west off Portland from 2009 to 2018. In analysing this data (2002 – 2019), Aulich *et al*. (2022) found that fin whale detections showed yearly variations but occurred in the temporal window from July to October at a low rate (detected in just 0.02 % of total recording hours; Aulich *et al*., 2019). This indicates an inconsistent and irregular presence of fin whales in this region and suggests that few animals migrate to the south coast of Australia (Aulich *et al*., 2022).

The extent of occurrence and areas of occupancy of fin whales in south-east coast Australian waters is unknown due to the rarity of sightings records, however given the wide-ranging nature of this species, the confirmed sightings in the Bonney Upwelling and the acoustic detections in waters off Portland, there is a '**moderate**' likelihood of encountering fin whales during the Otway Basin 3D MC MSS, particularly during summer and autumn months (from November through to May).

4.5.6.1.5 Sei Whale

Sei whales (*Balaenoptera borealis*) are found throughout the world's oceans but prefer temperate waters and offshore areas. Their preferred water temperature is between 8 and 18°C (Horwood, 2009) which is warmer than that preferred by most other baleen whales (Mizroch *et al.*, 1984). The sei whale is one of the least studied great whale species, and the current status of most populations is poorly known, as is the current abundance estimate for the southern hemisphere and Australian waters (DEH, 2005). Sei whales are currently listed as Endangered under the IUCN Red List, and in Australia they are listed as Vulnerable and Migratory under the EPBC Act 1999.

The movements and distributions of sei whales are unpredictable and not well documented, in part because sei whales are similar in appearance to Bryde's whales, which has resulted in confusion about distributional limits and frequency of occurrence, particularly in warmer waters where Bryde's whales are more common (DEH, 2005). It is thought that sei whales follow the same general migration pattern as most baleen whales; movement from low latitude feeding grounds to higher latitude feeding grounds, although the timing is generally later, and it is largely understood that they do not migrate to such high latitudes to feed (DEH, 2005). In the Southern Hemisphere, breeding occurs in tropical and subtropical waters between April and August, however there are no known mating or calving areas in Australian waters (DoCCEEW, 2023).

Sei whales do not often occur near coasts and sightings are infrequently reported from Australian waters (Bannister *et al*., 1996). However, a small number of sightings have been reported from VIC waters and those off TAS (Kato *et al.,* 1996; Gill, 2002), mainly during summer and early autumn months (Gill, 2002). A total of 12 sei whales were sighted during annual aerial surveys (from 2002 – 2013) 20 – 60 km offshore on the continental shelf in the Bonney Upwelling (Miller *et al*., 2012) during November to May (Gill *et al*., 2015). On one occasion, a cow-calf pair was sighted, and feeding behaviour was observed on five occasions (Gill *et al*., 2015). Additionally, sei whales have been reported 200 NM south-west of Port Lincoln in December, and a concentration of sei whales was reported as the western end of the Bass Strait (Kato *et al*., 1996). Females with calves have also been observed south of TAS (Ensor *et al*., 2002).

Sei whale vocalisations have been recorded as low-frequency down-sweep calls that sweep from 82 to 34 Hz over 1.4 seconds, most often produced as a single call but occasionally as pairs or triplicates (Baumgartner *et al*., 2008). As well as low-frequency tonal and swept calls, McDonald *et al.* (2005) also recorded broadband sounds described as 'growls' or 'wooshes'. The maximum source level of tonal calls recorded by McDonald (2006) was 156 ±3.6 dB re 1 µPa @ 1 m.

The extent of occurrence and areas of occupancy of sei whales in Australian waters is poorly known due to the rarity of sightings records, however the confirmed sightings in the Bonney Upwelling indicate that sei whales may be encountered during the Otway Basin 3D MC MSS. On this basis, the likelihood of encountering sei whales during the Otway Basin 3D MC MSS has been assessed to be '**moderate**'.

4.5.6.1.6 Antarctic Minke Whale

The Antarctic minke whale (*Balaenoptera bonaerensis*) is found throughout the Southern Hemisphere, occupying primarily offshore and pelagic habitats within cold temperate to Antarctic waters between 21°S and 60°S (Bannister *et al*., 1996). This species is currently listed as Data Deficient under the IUCN Red List, and in Australia they are listed as Migratory under the EPBC Act 1999.

Antarctic minkes undergo extensive migrations between summer feeding grounds in Antarctica and winter sub-tropical to tropical breeding grounds (Perrin and Brownell, 2002). The northward range of Antarctic minkes is restricted by the presence of warmer waters extending south along Australia's coasts (DoCCEEW, 2023). Zerbini *et al*. (1997) noted that Antarctic minke whales occupy pelagic waters extending up to 600 m depth while on breeding grounds.

The distribution of Antarctic minke whales off Australia is primarily assumed from incidental sightings and beach-cast animals (DoCCEEW, 2023). Gill *et al*. (2015) reported one sighting of a whale assumed to be an Antarctic minke whale during aerial surveys in South Australian waters (eastern GAB to western Bass Strait) between 2002 – 2013. Based on sighting records, Arnold *et al*. (1987) suggests minke whale abundances in Australian waters peak in July and August.

'Bio-duck' sounds that are characteristic of Antarctic minke whales were recorded in the Perth Canyon, Western Australia during July and August (Erbe *et al*., 2015), and around Scott Reef, north-west of Cape Leveque, Western Australia in July, September and October (McCauley, 2011).

The extent of occurrence and areas of occupancy of Antarctic minkes in Australian waters is unknown due to the rarity of sightings records, however given the offshore distribution of this species, and the possible sighting in the Bonney Upwelling, this species may be encountered during the Otway Basin 3D MC MSS. But based on the paucity of sighting records, the likelihood of encountering minke whales during the Otway Basin 3D MC MSS has been assessed to be '**low**'.

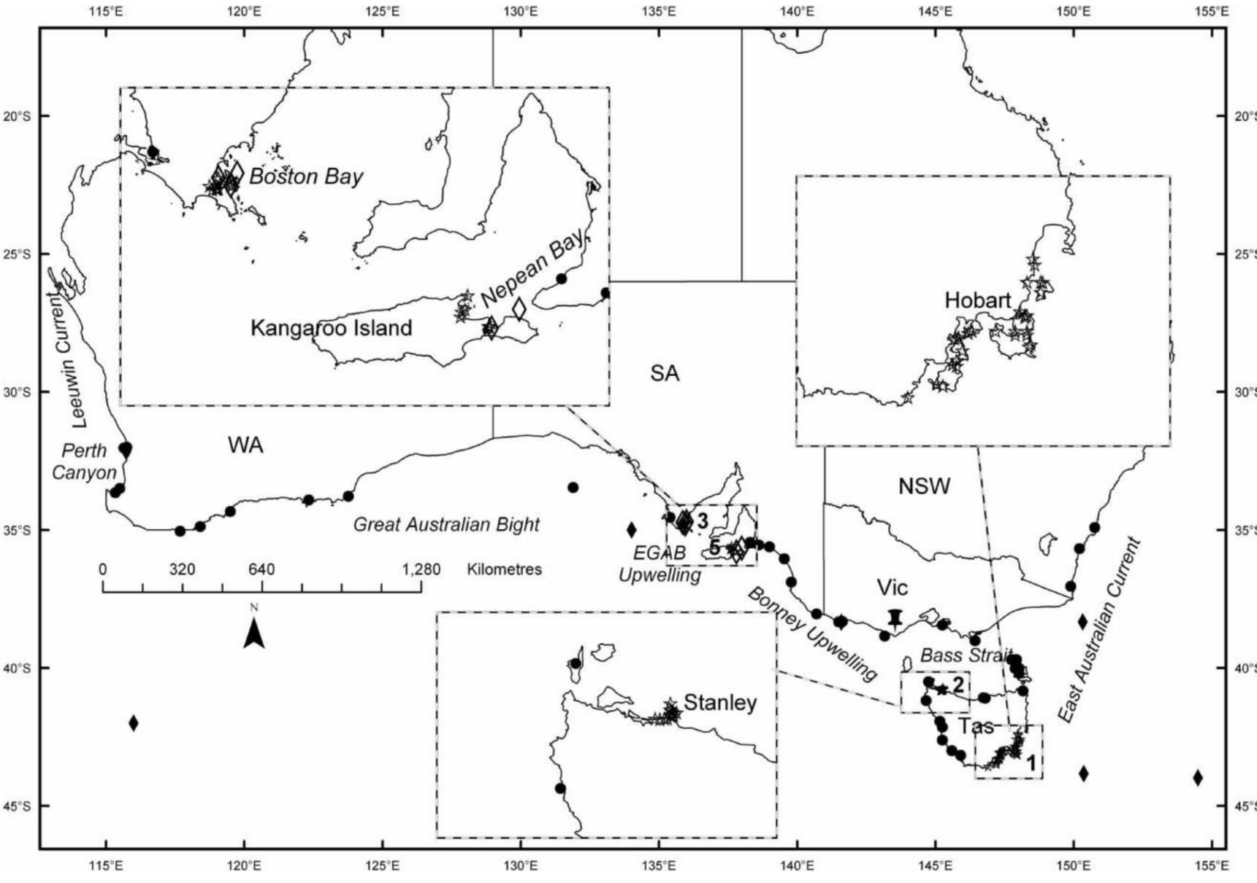
4.5.6.1.7 Pygmy Right Whale

The pygmy right whale (*Caperea marginata*) is found in temperate and sub-Antarctic waters of the Southern Hemisphere preferring surface water temperatures of 5 – 20°C (Kemper, 2002). Pygmy right whales are not known to be migratory, however they may move north/south depending on reproductive and life history status (Kemper, 2002). This species is listed as Least Concern under the IUCN Red List, and in Australia they are listed as Migratory under the EPBC Act 1999.

Pygmy right whales are the smallest, most cryptic and least known of the living baleen whales (Fordyce and Marx, 2012). While pygmy right whales are rarely sighted at sea and most of what is known comes from strandings, there have been more sightings of pygmy right whales in Australian waters than anywhere else in their range (Kemper, 2002). In particular, South Australia and western VIC reported more stranding and sighting events (32% of all Australian records) than other regions on Australia's mainland, and overall had the most sightings of live whales.

In South Australia/West VIC (Bonney Upwelling region), there have been six sightings and 35 carcasses (including strandings, entanglements and intentional killings) recorded for the period 1884 to early 2007 (Kemper *et al*., 2013). Sightings of live whales in this region were almost all very close to shore, within 2 km (Kemper *et al.*, 2013). From this data, Kemper *et al.* (2013) identified a number of coastal 'hot spots' for this species (**Figure** 36); namely Boston Bay and Nepean Bay in South Australia (587 km and 404 km northwest of the OA respectively), and Stanley, northwest TAS (135 km to the east of the OA). Several sighted whales were observed within the hotspots for more than one day, suggesting that these animals were not simply transiting the area. Pygmy right whale sightings were most frequent from September to February, with an additional peak in June (Kemper *et al*., 2013), coinciding with a sighting by Gill *et al*. (2008). Gill *et al*. (2008) reported a single sighting of 100 pygmy right whales in June 2007, approximately 40 km south-south-west of Portland in the Bonney Upwelling in water depths of 150 m, approximately 4 km from the 200 m shelf break. This sighting reportedly contained a range of size classes, including calves, near an area where abundant krill surface swarms were present at the time (Gill *et al*., 2008; 2015). In support of this, Kemper *et al*. (2013) found that pygmy right whales were likely feeding in zooplankton rich areas including the Bonney Upwelling.

Little information is known on the vocalisations of pygmy right whales, although it has been assumed that communication is similar to other baleen whales, in that this species communicates using loud low-pitched sounds (WhaleFacts, 2023). Recordings of a juvenile pygmy right whale documented paired short thump-like pulses or tone bursts with a down-sweep in frequency and decaying amplitude. Most of the energy of this call was between 60 and 120 Hz. Recorded source levels were in the lower end of the range of other baleen whales (Dawbin and Cato, 1992).



Source: Kemper *et al.,* 2013

Figure 36 Distribution of Pygmy Right Whale Stranding's and Sightings off Australia

Given the presence of a pygmy right whale 'hotspots' in waters adjacent to the OA, and the confirmed sightings of this species in the Bonney upwelling, pygmy right whales may be encountered during the Otway Basin 3D MC MSS in nearshore waters. Therefore, the likelihood of encountering pygmy right whales during the Otway Basin 3D MC MSS has been assessed to be '**moderate**'.

4.5.6.2 Cetaceans – Toothed Whales and Dolphins

4.5.6.2.1 Sperm Whale

Sperm whales (*Physeter microcephalus*) have a cosmopolitan distribution throughout deep waters off the continental shelf (i.e. beyond 200 m water depth). While sperm whales have been recorded in all Australian waters (Bannister *et al*., 1996), females and young are restricted to warmer waters north of 45°S, while males travel to and from colder waters and to Antarctic pack-ice (Johnson, 2013). While sperm whales do not undertake large-scale migrations along pre-determined routes, they can and do move considerable distances between foraging locations (Whitehead, 1996). Sperm whales are listed as Vulnerable under the IUCN Red List, and in Australia they are listed as Migratory under the EPBC Act 1999.

Sperm whales tend to inhabit offshore areas with a water depth of 600 m or more and are uncommon in waters less than 300 m deep. Concentrations of sperm whales are found where the sea floor rises steeply from great depth, particularly in submarine canyons and are associated with concentrations of major food in areas of upwelling (Bannister *et al.*, 1996; Moors-Murphy, 2014).

Key locations for sperm whales in southern Australia include the area between Cape Leeuwin and Esperance, Western Australia, the region south-west of Kangaroo Island, South Australia, and deep waters off the TAS west and south coasts (DoCCEEW, 2023). Deep canyons off the South Australia coast and associated upwellings are known to provide a food source for sperm whales. Sperm whales are deep and prolonged divers and can therefore feed throughout the entire water column, even in very deep areas. However, they seem to forage mainly on or near the bottom, often ingesting stones, sand, sponges, and other non-food items (Rice, 1989; Whitehead *et al*., 1992). Watkins *et al*. (1993) noted that sperm whales have been recorded to dive to depths exceeding 1,185 m for over one hour whilst feeding.

Aerial surveys in continental shelf and slope waters off southern Australia (eastern GAB to western Bass Strait) from 2002 – 2013 recorded a total of 34 sperm whale sightings, with 66 individual sperm whales sighted (Gill *et al*., 2015). The greatest number of sightings occurred in October and November, with no sightings between June and September (Gill *et al*., 2015). Only adult sperm whales were sighted, with 68% of sightings of solitary males, and the remaining 32% were groups of 2 – 12 similarly sized animals (Gill *et al*., 2015). A previous 2D seismic survey over the OA recorded five sightings of 17 sperm whales, mainly on the continental slope (Seiche Environmental, 2020; **Figure 27**).

This species is reliant on echolocation to locate prey and for navigation. The echolocation clicks that sperm whales use during foraging enable them to determine the direction and distance of prey (Ocean Research Group, 2015). Clicks are also produced as a means of communication, to identify members of a group and to coordinate foraging activities (Andre and Kamminga, 2000). Sperm whale clicks have been reported to be multi-pulsed and broadband, ranging in frequency from 0.2 – 32 kHz (Backus and Schevill, 1966). Clicks from foraging male sperm whales have been recorded with source levels up to 236 dB re 1 µPa @ 1 m (Madsen *et al.,* 2002; Møhl *et al.,* 2003).

There are no BIAs for sperm whales within the OA, however a foraging BIA is located within the EMBA, approximately 326 km northwest of the OA (**Figure 25**). The foraging BIA is utilised by sperm whales throughout the year, with whales most abundant during August and September. The likelihood of encountering sperm whales during the Otway Basin 3D MC MSS has been assessed to be '**moderate**' based on their cosmopolitan distribution in offshore waters and the presence of sperm whale concentrations in the vicinity of the OA.

4.5.6.2.2 Killer Whale

Killer whales (*Orcinus orca*) (also known as orca) are distributed throughout all marine regions from the equator to polar waters (Reeves *et al.*, 2017); however, they are most numerous in coastal waters and cooler regions where productivity is high (DoCCEEW, 2023). There are no population estimates for the killer whale, globally or within Australia (DoCCEEW, 2023). The killer whale is currently listed as Data Deficient under the IUCN Red List, and in Australia they are listed as Migratory under the EPBC Act 1999.

In Australia, killer whale sightings have been reported from all states, with concentrations reported from around TAS, with animals also frequenting waters off VIC (Ling, 1991). They are often observed along the continental slope and on the shelf, particularly around seal colonies (Ross, 2006). High numbers of killer whale strandings have been reported within the SEMR, suggesting regionally significant populations may be present (CoA, 2015). Killer whales are known to make seasonal movements and although little is known of movement patterns, it is likely that the presence of killer whales in the OA is highest in winter months.

In VIC, killer whales were sighted in 2015, 2016, 2017, 2018 and 2019, including off Portland in August 2019 (SWIFFT, 2021b). Gill *et al*. (2015) reported six sightings, comprising 21 individual killer whales (mean group size 3.5 ± 2.8 whales), during aerial surveys in South Australian waters (eastern GAB to western Bass Strait) in 2002/2003, 2003/2004, 2006/2007 and 2011/2012. Sightings occurred predominantly in March and May, with additional sightings in July and December. Killer whales were predominantly sighted on the shelf close to the shelf break, in an average water depth of 171 ± 135 m (Gill *et al*., 2015). In South Australia, killer whale sightings were mostly coastal, with concentrations of sightings found along the west coast of Eyre Peninsula and around Kangaroo Island (Kemper, 2008). Sightings were reported in all months except August, with sightings most frequent in July (Kemper, 2008).

Echolocation characteristics vary between groups of whales and are thought to reflect the target prey species of a particular group (Barrett-Lennard *et al*., 1996). Whistles have an average dominant frequency of 8.3 kHz (Thomsen *et al*., 2001) and variations of these whistles (often referred to as dialects) have been documented between pods (Deecke *et al*., 2000).

There is no known foraging or breeding areas for killer whales within or adjacent to the OA, however given the frequent sightings of killer whales in South Australia and VIC waters, and the confirmed sightings of killer whales in the Bonney Upwelling, killer whales may be encountered during the Otway Basin 3D MC MSS. The likelihood of killer whales being encountered during the Otway Basin 3D MC MSS has been assessed as '**moderate**'.

4.5.6.2.3 False Killer Whale

False killer whales (*Pseudorca crassidens*) are widespread in deep tropical and warm temperate waters (Odell and McClune, 1999). Although false killer whales are widely distributed throughout Australia (based on stranding records), they are not considered to be abundant (Ross, 2006). The false killer whale is currently listed as Near Threatened under the IUCN Red List and are not listed under the EPBC Act 1999.

High stranding numbers of false killer whales in the SEMR (including in VIC, South Australia and TAS) suggest that regionally significant populations may occur in this region (CoA, 2015). Trends in stranding events suggest a seasonal movement inshore or along the continental shelf on Australia's south-east coast between May and September (Nicol, 1987; Bannister *et al*., 1999). However, during aerial surveys off continental shelf and slope waters of southern Australia (eastern GAB to western Bass Strait) from 2002 – 2013, no false killer whale detections were made (Gill *et al*., 2015). False killer whales utilise deep offshore waters and sometimes deep coastal waters where the continental shelf is narrow (Culik, 2005).

False killer whales are extremely vocal with a diverse repertoire consisting of click trains, burst-pulse sounds, and whistles. Peak frequencies of false killer whale sounds recorded from captive animals ranged from 3 to 22 kHz (Murray *et al*., 1998).

No biologically important habitat has been reported in proximity of the OA, therefore the likelihood of encounter of false killer whales during the Otway Basin 3D MC MSS has been assessed as '**low**'.

4.5.6.2.4 Long-finned Pilot Whale

Long-finned pilot whales (*Globicephala melas*) are widespread and relatively common throughout the Southern Hemisphere (Ross, 2006). They inhabit temperate and sub-Antarctic deep oceanic waters and zones of high productivity along the continental slope, venturing into shallower waters (<200 m) in search of prey (Ross, 2006). The long-finned pilot whale is currently listed as Least Concern under the IUCN Red List and are not listed under the EPBC Act 1999.

High numbers of long-finned pilot whales have stranded along the VIV and TAS coasts (Ross, 2006), suggesting that regionally significant populations may be present (CoA, 2015). Mass stranding events along the Australian coast suggest a seasonal occurrence, with events historically occurring from September – March, with 60% of those occurring from December to March (Bannister *et al*., 1996).

Aerial surveys over continental shelf and slope waters off southern Australia (eastern GAB to western Bass Strait) from 2002 – 2013 recorded a total of 40 long-finned pilot whale sightings, with 1,853 individuals sighted (Gill *et al*., 2015). All sightings occurred in the months between November and May, with no sightings between June and October (Gill *et al*., 2015). A previous 2D seismic survey over the OA from January to April 2020 recorded two sightings of this species (Seiche Environmental, 2020; **Figure 27**).

Pilot whales are known to be highly vocal when socialising at the surface (Jensen *et al.,* 2011), with vocalisations ranging from simple whistles while resting at the surface to complex whistles and pulses sounds during active behaviours (Weilgart and Whitehead, 1990). Calls of deep-diving pilot whales have been recorded with median peak frequencies of 3.9 kHz (Jensen *et al.,* 2011).

Due to the relatively high number of stranding records for the VIC coast, there is potential that the OA is spatially and/or temporally proximate to areas that provide important habitat for this species. As a result, the likelihood of encountering pilot whales during the Otway Basin 3D MC MSS has been assessed to be '**moderate**'.

4.5.6.2.5 Dusky Dolphin

The dusky dolphin (*Lagenorhynchus obscurus*) occurs coastally throughout the Southern hemisphere, mostly in temperate and sub-Antarctic zones between about 26°S and 55°S (DoCCEEW, 2023). They are presumed to be primarily an inshore species; however, they may be pelagic at times (Ross, 2006). Currently, dusky dolphins are listed as Least Concern under the IUCN Red List, and in Australia they are listed as Migratory under the EPBC Act 1999.

Although identified as potentially present within the SEMR (CoA, 2015), they are considered to be rare in Australian waters (Ross, 2006). Indeed, dusky dolphin presence in Australia, is known only from 13 reports since 1982 (DoCCEEW, 2023). However, available data suggests that hey occur across southern Australia, from Western Australia to TAS, with confirmed sightings near Kangaroo Island, South Australia and off TAS and VIC, and unconfirmed sightings south of continental Australia (Ross, 2006; DoCCEEW, 2023). It is noteworthy that all sightings of dusky dolphins in Australian waters have been correlated with abnormally warm sea surface temperatures (more than 0.5 °C above normal temperature) (Gill *et al*., 2000). Dusky dolphins are resident inshore for much of year but are known to seek out colder water (<18 C) as inshore temperatures rise in summer (Ross, 2006). Mating and calving is presumed to occur in summer, although no calving areas are known in Australian waters (Ross 2006).

The extent of occurrence and areas of occupancy of dusky dolphins in Australian waters is unknown due to the rarity of sightings records, however given their presence across southern Australia, dusky dolphins may be encountered during the Otway Basin 3D MC MSS. However, the likelihood of encounter of this species during the Otway Basin 2DMC MSS has been assessed as '**low**'.

4.5.6.2.6 Common Dolphin

Common dolphins (*Delphinus delphis*) occur over continental shelf and pelagic waters of the Atlantic and Pacific Oceans (Reeves *et al*., 2002). Their occurrence in Australian waters is poorly studied, with stranding and incidental capture records the main sources of information (Filby *et al.,* 2010). Common dolphins are listed as Least Concern under the IUCN Red List and are not listed under the EPBC Act 1999.

Filby *et al.* (2010) carried out the first distribution and abundance survey for common dolphins in South Australia waters. Although common dolphins were observed in all months surveyed (suggesting that populations are resident), a summer seasonality to sightings was evident, with more encounters and larger groups recorded from December to April (Filby *et al*., 2010). Dolphins were only found in water depths less than 40 m (Filby *et al.,* 2010). While this survey was carried out to the west of the OA, it provides an indication to the potential distribution and seasonality of common dolphins within the OA. Based on the high numbers of common dolphin stranding events, including a mass stranding of 34 animals in VIC (Ross, 2006), regionally significant populations of common dolphins may be found in the SEMR (CoA, 2015).

Aerial surveys over continental shelf and slope waters off southern Australia (eastern GAB to western Bass Strait) from 2002 – 2013 recorded a total of 384 dolphin sightings, and while species could not always be reliably identified these sightings were assumed to be either common dolphins or bottlenose dolphins, and most likely the sightings are a mix of both species (Gill *et al*., 2015). Dolphin sightings occurred in all months except August and September (Gill *et al*., 2015). A previous 2D seismic survey over the OA from January to April 2020 recorded multiple sightings of this species (Seiche Environmental, 2020; **Figure 27**).

Common dolphins are highly vocal animals, and use a variety of vocalisations including whistles, echolocation click-trains, burst pulse calls (Richardson *et al.,* 1995; Soldevilla *et al,* 2008), and other non-whistle pulsed sounds referred to as barks, yelps, or squeals (Ridgway, 1983). The average frequency and length of whistles are 10 – 14 kHz and 0.27 seconds, respectively (Petrella *et al*., 2012).

Common dolphins have been assessed as having a '**moderate**' likelihood of encounter during the Otway Basin 3D MC MSS as although the majority of the OA occurs in water depths greater than 200 m, common dolphins are expected to be encountered in the inshore portions of the survey as occurred during the previous Otway Basin 2D MC MSS (**Figure 27**).

4.5.6.2.7 Bottlenose Dolphin

Bottlenose dolphins (*Tursiops truncatus* and *Tursiops aduncus*) are widespread in cold temperate and tropical seas, where they inhabit a range of habitats including bays, lagoons, estuaries, open coasts, and pelagic waters (Möller *et al.,* 2002). The distribution on bottlenose dolphins is continuous around mainland Australia, but the taxonomy of many populations is unclear. Indeed, the taxonomy of the *Tursiops* genus is currently under review and recently a novel species of bottlenose dolphin (*Tursiops australis*) has been identified to inhabit inshore waters of VIC (Möller *et al.,* 2008). Bottlenose dolphins are listed as Least Concern (*Tursiops truncatus*) and Near Threatened (*Tursiops aduncus*) under the IUCN Red List and no *Tursiops* species are currently listed under the EPBC Act 1999.

In Australian waters bottlenose dolphins are usually found in depths >30 m (Hale *et al*., 2000; Kemper, 2004). Bilgmann *et al*. (2007) suggests that female bottlenose dolphins tend to be resident to particular areas, while males' range further. High numbers of bottlenose dolphin strandings have occurred in the SEMR, suggesting that regionally significant populations may exist here (CoA, 2015).

Aerial surveys over off southern Australia (eastern GAB to western Bass Strait) from 2002 – 2013 recorded a total of 384 dolphin sightings, and while species could not always be reliably identified these sightings were assumed to be either bottlenose dolphins or common dolphins, but most likely the sightings events are a mix of both species (Gill *et al*., 2015). Dolphin sightings occurred in all months except August and September (Gill *et al*., 2015). On four occasions dolphins were positively identified to be bottlenose dolphins and these sightings occurred in September, November, and December. A previous 2D seismic survey over the OA from January to April 2020 recorded one sighting of this species (Seiche Environmental, 2020; **Figure 27**).

Bottlenose dolphins produce 'clicks' which are used for echolocation purposes (0.8 – 24 kHz) and 'whistles' which are used as a form of communication (40 – 130 kHz).

The OA mostly occurs in waters deeper than those preferred by bottlenose dolphins; therefore, the likelihood of bottlenose dolphins being encountered during the survey has been assessed as '**low**'.

4.5.6.3 Pinnipeds (Otariids – Sea Lions and Fur Seals)

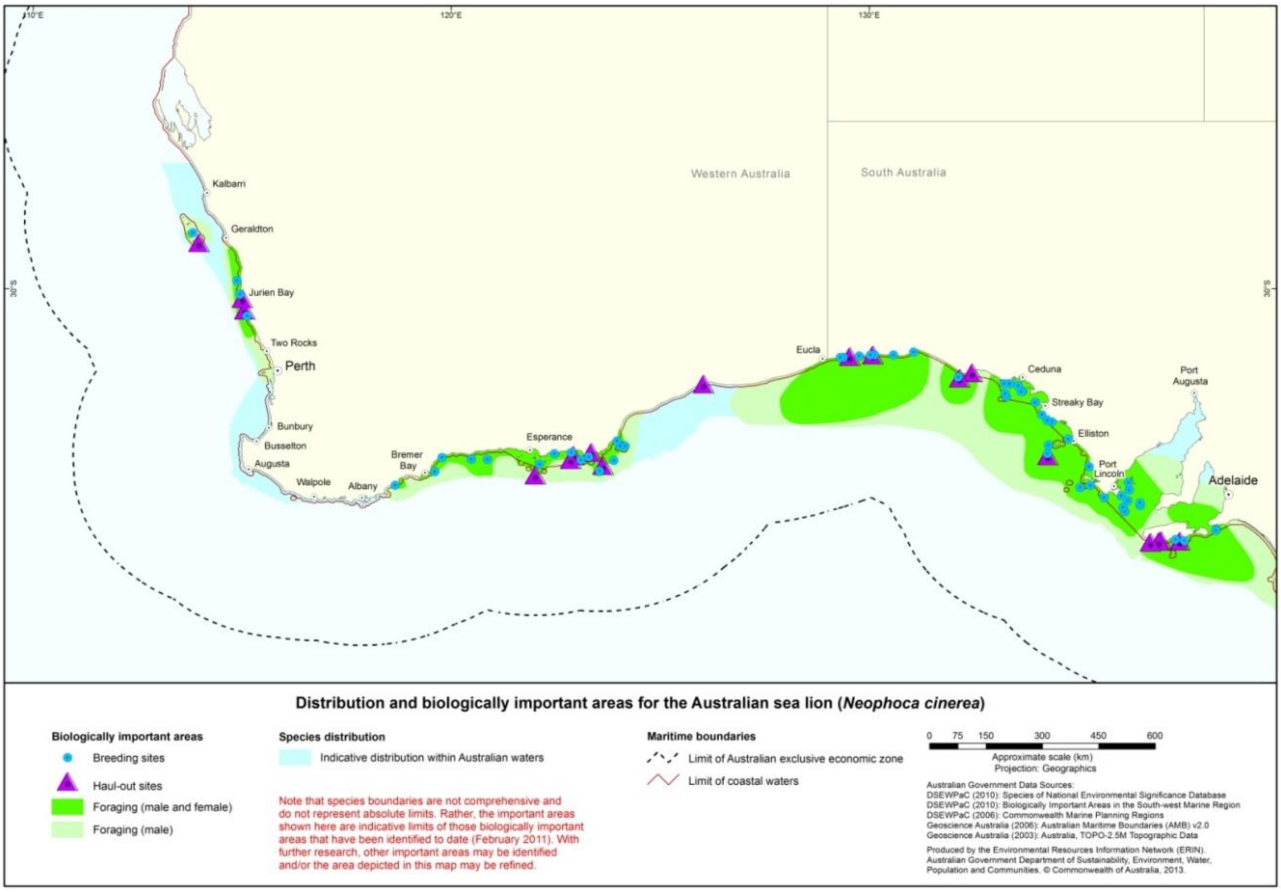
4.5.6.3.1 Australian Sea Lion

The Australian sea lion (*Neophoca cinerea*) is the only pinniped species endemic to Australia. The contemporary distribution of Australian sea lions is restricted to Southern and Western Australia (Shaughnessy *et al*., 2011), and the current breeding distribution occurs mostly on islands of South Australia and Western Australia, with only a number of small mainland breeding sites at the base of cliffs (between Pages Islands just off the east side of Kangaroo Island to Easter Island in the Abrolhos Islands, Western Australia) (Goldsworthy *et al*., 2021) (**Figure 37**). The range of this species was severely restricted following commercial sealing in the late eighteenth and early nineteenth century, with the historical range thought to have extended into Bass Strait (Ling, 1999). Currently, the Australia sea lion is listed as Endangered under the IUCN Red List, and in Australia they are listed as Endangered under the EPBC Act 1999.

Australia sea lions are unique among pinnipeds in that they have a non-annual breeding cycle of around 17 – 18 months, with the longest gestation of any pinniped of up to 14 months (Goldsworthy *et al*., 2021). In addition, this species has a temporally asynchronous breeding cycle (i.e. the period of mating and parturition in one colony will occur at a different time to that in another colony. Females typically remain within 60 km of their natal site, while males disperse approximately 200 km from natal sites (Campbell, 2003).

There is evidence of significant declines in abundance across parts of the Australian sea lions' range, with total population estimates ranging between 10,000 to 15,000 individuals (Goldsworthy *et al*., 2015). Goldsworthy *et al*. (2021) report a decline in pup abundance of 2% per annum, with an overall decline of 64% over three generations (~42 years). Pup production is c.2,700 per annum, of which 82% occur in SA (Goldsworthy *et al*., 2021).

Australian sea lions are known to forage on the continental shelf, most commonly in depths of 20 – 100 m in Commonwealth waters adjacent to breeding sites (Shaughnessy, 1999) (**Figure 37**). Foraging trips average around 60 km from the colony, with a maximum distance of around 190 km when over shelf waters (Hamer *et al*., 2011). Australian sea lions are benthic foragers, primarily feeding on the seabed (Goldsworthy *et al*., 2021). Their diet is varied, and includes fish, cephalopods, sharks, rock lobster, and sea birds (Shaughnessy, 1999).



Source: CoA, 2013

Figure 37 Distribution of the Australian Sea Lion

The OA is located east of the distributional range for Australian sea lions; hence there is no overlap between the OA and any BIAs for this species. However, two foraging BIAs for Australian sea lions are located within the EMBA; a foraging BIA (male) is located approximately 97 km northwest of the OA and a foraging BIA (male and female) is located approximately 312 km northwest of the OA (see **Figure 26**). The closest breeding colony to the OA is located within the Pages Island group, over 360 km northwest of the OA (DoCCEEW; 2023).

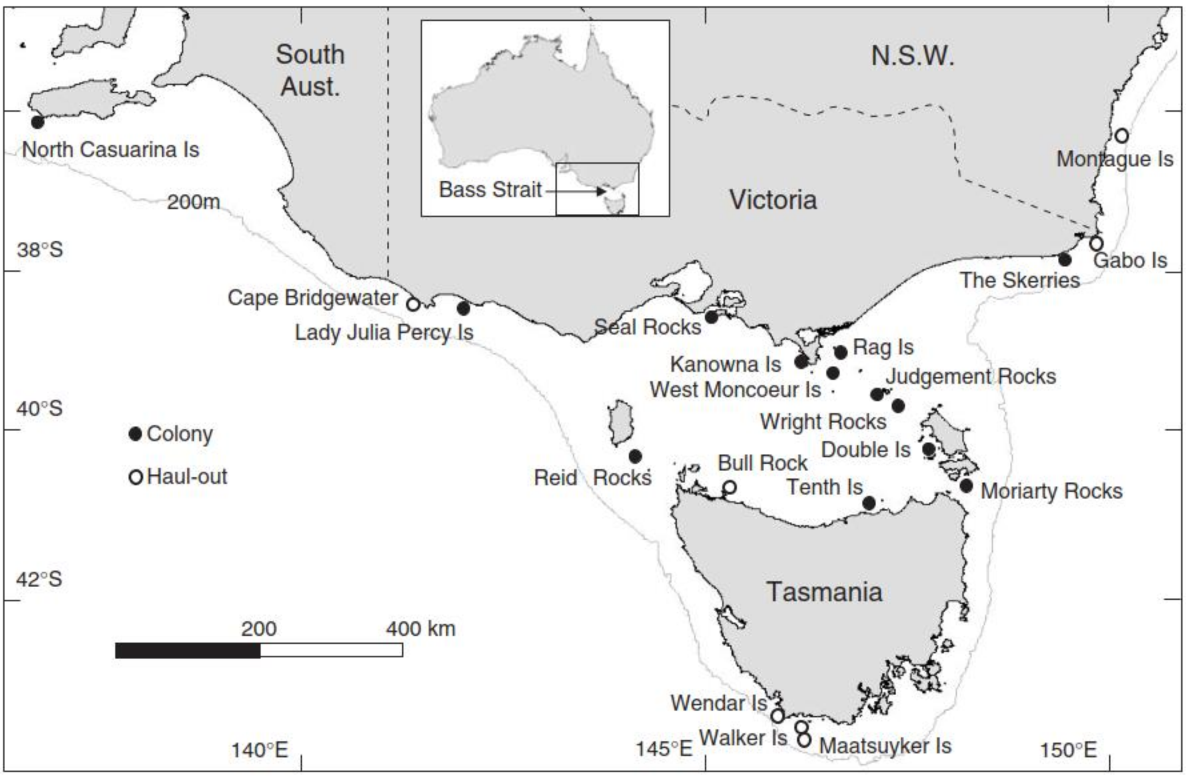
As the OA occurs outside the typical distributional range for Australian sea lions, the likelihood of encountering this species during the Otway Basin 3D MC MSS has been assessed as '**low**'.

4.5.6.3.2 Australian Fur Seal

The Australian fur seal (*Arctocephalys pusillus*) utilises rocky island habitat that includes flat, open terrain. The population of Australian fur seals was severely reduced during commercial sealing operations in the 1800s and early 1900s (Warneke and Shaughnessy, 1985), and the population is still in the recovery phase. This species is currently listed as Least Concern under the IUCN Red List, and they are not listed under the EPBC Act 1999.

The most recent population estimate for this species is 120,000 individuals (Kirkwood *et al*., 2010). Pup production is largely restricted to northern Bass Strait (Kirkwood *et al*., 2010) where ten established breeding colonies occur (**Figure 38**), six of which are located off the coast of VIC and four off the coast of TAS (DoCCEEW, 2023). The largest established breeding colonies are found on Lady Julia Percy Island (approximately 45 km north of the OA) which supports c. 26% of the breeding population; and at Seal Rocks (201 km northeast of the OA) which supports 25% of the breeding population (Kirkwood *et al*., 2010).

Additional breeding colonies in the vicinity of the OA include Cape Bridgewater, approximately 32 km north of the OA, North Casuarina Island, South Australia, approximately 440 km northwest, and Reid Rocks, TAS, approximately 58 km east of the OA (Kirkwood *et al*., 2010). Individual Australian fur seals may migrate north over winter, returning to Bass Strait breeding colonies in late spring (Shaughnessy *et al*., 2001); however, breeding colonies are occupied year-round. The Australian fur seal has a single annual pupping period in the austral summer from late October to late December (DoCCEEW, 2023), with 90% of pups born in a 3 – 4-week period with a peak in early December (Gibbens and Arnould, 2009). Following the birth of their pups, females' alternate periods feeding at sea with periods at shore to suckle their pups. Pups begin to forage in June and July, with the majority fully weaned by September – October (Shaughnessy, 1999).



Source: Kirkwood et al. (2010)

Figure 38 Distribution of Australian Fur Seals

Australian fur seals are predominantly benthic foragers on the shallow (< 100 m) continental shelf of Bass Strait, feeding on a wide variety of prey types comprising bony fish, elasmobranchs, and cephalopods (Speakman *et al*., 2020). Fish species of note in the diet of this species are redbait, leatherjacket, and jack mackerel, with seabirds also opportunistically taken (Warneke and Shaughnessy, 1985). Fish comprise the majority of the diet in winter, with cephalopods dominating in summer (Shaughnessy, 1999). Foraging may occur up to 500 km from a colony (Littnan and Arnould, 2002) and appears to peak in autumn and winter (Lyle and Willcox, 2008), when males and females are building up their energy reserves for the pupping season and females are maintaining milk reserves for their young. Lactating females were found to forage exclusively within the shallow waters over the continental shelf of Bass Strait, where water depths are around 60-80 m and sea surface temperature is 16- 16.8 °C (Arnould and Kirkwood, 2008).

Given the close proximity of the OA to breeding colonies, and the extensive foraging range of this species, Australian fur seals are likely to be encountered during the Otway Basin 3D MC MSS. The likelihood of encounter during the Otway Basin 3DMC MSS has been assessed as '**moderate**'.

4.5.6.3.3 New Zealand fur seal

New Zealand fur seals (*Arctocephalus forsteri)* (also known as the long-nosed fur seal) occur in both New Zealand and Australian waters with population numbers in Australia now estimated at around 117,400 (Chilvers and Goldsworthy, 2015). In Australia, this non-migratory species breeds at locations ranging from NSW to Western Australia (Shaughnessy *et al.,* 2015). This species was subject to commercial hunting in the late 18th and early 19th century but are currently listed as Least Concern under the IUCN Red List, and they are not listed under the EPBC Act 1999.

Most of the Australian population is located in South Australia, between Kangaroo Island and the southern tip of the Eyre Peninsula, with a single small breeding site at Baudin Rocks, located approximately 170 km northwest of the OA (Shaughnessy *et al*., 2015). The highest number of breeding sites (n=12) are found on Kangaroo Island (390 km northwest of the OA), accounting for 49.6% of the total pup abundance estimate for South Australia (Shaughnessy *et al*., 2015). Breeding sites in VIC include Cape Bridgewater, approximately 32 km north of the OA, Kanowna Island, and the Skerries, located approximately 273 km northeast and 590 km northeast of the OA, respectively (Kirkwood *et al*., 2009). Breeding takes place between October and January, with pups born from mid-November, and most born in December (Chilvers and Goldsworthy, 2015). Colonies are occupied year-round, with activity peaking during the summer breeding season (Shaughnessy, 1999). New Zealand fur seals are typically found along the coast on rocky parts of islands (Shaughnessy, 1999). Adult males begin defending coastal territories in late November, with onshore numbers peaking in early January (Goldsworthy and Shaughnessy, 1994). Adult females come to shore in early December and give birth soon after. Females continue to suckle their pups for several months, alternating between periods at sea and onshore feeding of pups (Shaughnessy, 1999).

Satellite tracking studies in South Australia found adult females forage in mid-outer shelf waters in regions associated with localised upwelling (Bonney Upwelling) approximately 70 – 90 km from breeding colonies in December to March, switching to foraging in distant oceanic waters associated with the sub-tropical front, approximately 700 - 1,000 km south of breeding colonies between April/May to September/October (Baylis *et al*., 2008). Satellite tracking studies of juveniles from Kangaroo Island showed that they typically forage in pelagic waters ~1,000 km further south in association with the sub-tropical front (Shaughnessy and Goldsworthy, 2020). Male New Zealand fur seals typically forage in deeper waters than females (Goldsworthy and Page, 2009). New Zealand fur seals mainly dive at depths between 10 to 70 m, but adult females are capable of maximum depths ranging from 106 to 225 m (Harcourt *et al.,* 1995; Harcourt and Davis, 1997).

The OA is spatially proximate to aggregation/breeding areas of New Zealand fur seals and the Bonney Upwelling, a recognised foraging area for New Zealand fur seals during the summer months. Therefore, the likelihood of New Zealand fur seals being encountered during the Otway Basin 3D MC MSS has been assessed as '**moderate**'.

4.5.7 Seabirds and Migratory Shorebirds

Over 100 species of seabird occur naturally or regularly visit Australia during their lifecycle. Coastal and oceanic habitats, particularly offshore islands and surrounding waters are critically important areas for seabirds during both the breeding and non-breeding seasons as places to breed, rest, and feed. For long-distance migratory species, these habitats also provide resources so birds can build enough energy reserves to complete their annual migration.

Several seabirds have been identified as potentially present within the OA and/or EMBA based on the EPBC Act Protected Matters Report (**Appendix D**). A list of the seabird species identified within the EPBC Act Protected Matters Report are provided in **Table 30**, with further descriptions on distribution, migration movements, preferred habitat and life stages of the threatened species provided in **Appendix F**.

The offshore distribution of seabirds is patchy, with birds congregating in areas where food is abundant (Reid *et al*., 2002). Several the seabirds identified as potentially present do not breed near the OA, as there are no islands within the OA to support breeding colonies, and seabirds breeding season will also determine the presence of seabirds. Therefore, not all the species identified in **Table 30** may be present during the Otway Basin 3D MC MSS.

Several seabird BIAs have been identified as relevant to the Otway Basin 3D MC MSS, based on the results contained within the EPBC Act Protected Matters Report. These BIAs are depicted in **Figure 39** – **Figure 44** and listed in **Table 31**.

Of the BIAs listed in **Table 31**, many have been identified as important areas for breeding. All areas identified as important breeding areas for seabirds are located inshore of the OA.

Table 30 Seabirds Identified as Present within the OA/EMBA

Name	Threat Category	Presence in OA and/or EMBA	Location of BIA
Red knot (*Calidris canutus*)	Endangered	Species or species habitat MAY occur in OA Species or species habitat KNOWN to occur within EMBA overfly marine area	No BIA
Curlew sandpiper (*Calidris ferruginea*)	Critically endangered	Species or species habitat MAY occur in OA	No BIA
Antipodean albatross (*Diomedea antipodensis*)	Vulnerable	KNOWN to occur in OA and EMBA Foraging, feeding or related behaviour LIKELY to occur within OA and EMBA	Foraging BIA in OA and EMBA
Southern royal albatross (*Diomedea epomophora*)	Vulnerable	Foraging, feeding or related behaviour LIKELY to occur within OA and EMBA	Foraging BIA in OA
Wandering albatross (*Diomedea exulans*)	Vulnerable	KNOWN to occur in OA LIKELY to occur in EMBA Foraging, feeding or related behaviour LIKELY to occur within OA and EMBA	Foraging BIA in EMBA
Northern royal albatross (*Diomedea sanfordi*)	Endangered	Foraging, feeding or related behaviour LIKELY to occur within OA and EMBA	No BIA

Name	Threat Category	Presence in OA and/or EMBA	Location of BIA
White-bellied storm-petrel (*Fregetta grallaria grallaria*)	Vulnerable	Species or species habitat LIKELY to occur within OA and EMBA	No BIA
Blue petrel (*Halobaena caerulea*)	Vulnerable	Species or species habitat MAY occur in OA and EMBA	No BIA
Southern giant petrel (*Macronectes giganteus*)	Endangered	KNOWN to occur in EMBA Foraging, feeding or related behaviour LIKELY to occur within OA and EMBA	Foraging BIA in EMBA
Northern giant petrel (*Macronectes halli*)	Vulnerable	KNOWN to occur in EMBA Foraging, feeding or related behaviour LIKELY to occur within OA and EMBA	Foraging BIA in EMBA
Eastern curlew (*Numenius madagascariensis*)	Critically endangered	Species or species habitat MAY occur in OA Species or species habitat KNOWN to occur in EMBA	No BIA
Fairy prion (*Pachyptila turtur subantarctica*)	Vulnerable	Species or species habitat MAY occur in OA Species of species habitat KNOWN to occur in EMBA	No BIA
Sooty albatross (*Phoebetria fusca*)	Vulnerable	Species or species habitat LIKELY to occur within OA and EMBA	No BIA
Gould's petrel (*Pterodroma leucoptera leucoptera*)	Endangered	Species or species habitat MAY occur in OA and EMBA	No BIA
Soft-plumaged petrel (*Pterodroma mollis*)	Vulnerable	Species or species habitat MAY occur in OA Breeding KNOWN to occur in EMBA	Foraging and breeding BIAs in EMBA
Australian fairy tern (*Sternula nereis nereis*)	Vulnerable	Species or species habitat LIKELY to occur within OA Species or species habitat KNOWN to occur in EMBA	No BIA
Buller's albatross (*Thalassarche bulleri*)	Vulnerable	KNOWN to occur in OA and EMBA Foraging, feeding or related behaviour LIKELY to occur within OA and EMBA	Foraging BIA in OA and EMBA
Northern Buller's albatross (*Thalassarche bulleri platei*)	Vulnerable	Species or species habitat LIKELY to occur within OA Foraging, feeding or related behaviour LIKELY to occur within EMBA	No BIA
Indian yellow-nosed albatross (*Thalassarche carteri*)	Vulnerable	KNOWN to occur in OA and EMBA Species or species habitat LIKELY to occur within OA and EMBA	Foraging BIA in OA and EMBA
Shy albatross (*Thalassarche cauta*)	Endangered	LIKELY to occur in OA Foraging, feeding or related behaviour LIKELY to occur within OA Breeding KNOWN to occur within EMBA	Foraging BIA in OA Foraging likely and breeding BIAs in EMBA
Grey-headed albatross (*Thalassarche chrysostoma*)	Endangered	Species or species habitat MAY occur in OA Foraging, feeding or related behaviour LIKELY to occur within EMBA	No BIA
Campbell albatross (*Thalassarche impavida*)	Vulnerable	KNOWN to occur in OA and EMBA Foraging, feeding or related behaviour LIKELY to occur within OA and EMBA	Foraging BIA in OA and EMBA

Name	Threat Category	Presence in OA and/or EMBA	Location of BIA
Black-browed albatross (*Thalassarche melanophris*)	Vulnerable	KNOWN to occur in OA and EMBA Foraging, feeding or related behaviour LIKELY to occur within OA and EMBA	Foraging BIA in OA and EMBA
Salvin's albatross (*Thalassarche salvini*)	Vulnerable	Foraging, feeding or related behaviour LIKELY to occur within OA and EMBA	No BIA
White-capped albatross (*Thalassarche steadi*)	Vulnerable	Foraging, feeding or related behaviour KNOWN to occur within OA and EMBA	Foraging BIA in EMBA
Flesh-footed shearwater (*Ardenna carneipes*)	No threat listing	KNOWN to occur in EMBA Foraging, feeding or related behaviour LIKELY to occur within OA Species or species habitat KNOWN to occur in EMBA	Foraging BIA in EMBA
Sooty shearwater (*Ardenna grisea*)	No threat listing	KNOWN to occur in EMBA Species or species habitat MAY occur in OA Breeding KNOWN to occur in EMBA	Breeding and foraging BIAs in EMBA
Wedge-tailed shearwater (*Ardenna pacifica*)	No threat listing	LIKELY to occur in OA KNOWN to occur in EMBA	Foraging BIA in OA Foraging and breeding BIAs in EMBA
Short-tailed shearwater (*Ardenna tenirostris*)	No threat listing	KNOWN to occur in OA and EMBA Breeding KNOWN to occur in EMBA	Foraging BIA in OA Foraging and breeding BIAs in EMBA
Australasian gannet (*Morus serrator*)	No threat listing	KNOWN to occur in OA and EMBA Breeding KNOWN to occur within EMBA	Foraging BIA in OA Aggregation and foraging BIAs in EMBA
White-faced storm petrel (*Pelagodroma marina*)	No threat listing	KNOWN to occur in OA and EMBA Breeding KNOWN to occur in EMBA	Foraging BIA in OA Foraging and breeding BIAs in EMBA
Common diving-petrel (*Pelecanoides urinatrix*)	No threat listing	KNOWN to occur in OA and EMBA Breeding KNOWN to occur in EMBA	Foraging BIA in OA Foraging and breeding BIA in EMBA
Tasmanian wedge-tailed eagle (*Aquila audax fleayi*)	Endangered	Breeding LIKELY to occur in EMBA	No BIA
Gibson's albatross (*Diomedea antipodensis gibsoni*)	Vulnerable	Foraging, feeding or related behaviour LIKELY to occur within EMBA	No BIA
Chatham albatross (*Thalassarche eremita*)	Endangered	Foraging, feeding or related behaviour MAY to occur within EMBA	No BIA
Caspian tern (*Hydroprogne caspia*)	No threat listing	Breeding KNOWN to occur within EMBA	No BIA
White-tailed tropicbird (*Phaethon lepturus*)	No threat listing	Species or species habitat MAY occur within EMBA	No BIA
Little tern (*Sternula albifrons*)	No threat listing	Breeding KNOWN to occur within EMBA	No BIA
Magpie goose (*Anseranas semipalmata*)	No threat listing	Species or species habitat MAY occur within EMBA overfly marine area	No BIA

Name	Threat Category	Presence in OA and/or EMBA	Location of BIA
Fork-tailed swift (*Apus pacificus*)	No threat listing	Species or species habitat LIKELY occur within EMBA overfly marine area	No BIA
Cattle egret (*Ardea ibis*)	No threat listing	Species or species habitat MAY occur within EMBA overfly marine area	No BIA
Curlew sandpiper (*Calidris ferruginea*)	Critically endangered	Species or species habitat KNOWN occur within EMBA overfly marine area	No BIA
Pectoral sandpiper (*Calidris melanotos*)	No threat listing	Species or species habitat KNOWN occur within EMBA overfly marine area	No BIA
Red-necked stint (*Calidris ruficollis*)	No threat listing	Roosting KNOWN to occur within EMBA overfly marine area	No BIA
Great knot (*Calidris tenuirostris*)	Critically endangered	Roosting KNOWN to occur within EMBA overfly marine area	No BIA
Black-eared cuckoo (*Chrysococcyx osculans*)	No threat listing	Species or species habitat KNOWN occur within EMBA overfly marine area	No BIA
Double-banded plover (*Charadrius bicinctus*)	No threat listing	Roosting KNOWN to occur within EMBA overfly marine area	No BIA
Red-capped plover (*Charadrius ruficapillus*)	No threat listing	Roosting KNOWN to occur within EMBA overfly marine area	No BIA
Latham's snipe (*Gallinago hardwickii*)	No threat listing	Species or species habitat KNOWN to occur within EMBA overfly marine area	No BIA
Swinhoe's snipe (*Gallinago megala*)	No threat listing	Roosting LIKELY to occur within EMBA overfly marine area	No BIA
Pin-tailed snipe (*Gallinago stenura*)	No threat listing	Roosting KNOWN to occur within EMBA overfly marine area	No BIA
Pied stilt (*Himantopus Himantopus*)	No threat listing	Roosting KNOWN to occur within EMBA overfly marine area	No BIA
White-throated needletail (*Hirundapus caudacutus*)	Vulnerable	Roosting KNOWN to occur within EMBA overfly marine area	No BIA
Kelp gull (*Larus dominicanus*)	No threat listing	Breeding KNOWN to occur within EMBA	No BIA
Pacific gull (*Larus pacificus*)	No threat listing	Breeding KNOWN to occur within EMBA	No BIA
Swift parrot (*Lathamus discolor*)	Critically endangered	Breeding KNOWN to occur within EMBA overfly marine area	No BIA
Broad-billed sandpiper (*Limicola falcinellus*)	No threat listing	Roosting KNOWN to occur within EMBA overfly marine area	No BIA
Black-tailed godwit (*Limosa limosa*)	No threat listing	Roosting KNOWN to occur within EMBA overfly marine area	No BIA
Rainbow bee-eater (*Merops ornatus*)	No threat listing	Species or species habitat MAY occur within EMBA overfly marine area	No BIA
Black-faced monarch (*Monarcha melanopsis*)	No threat listing	Species or species habitat KNOWN occur within EMBA overfly marine area	No BIA

Name	Threat Category	Presence in OA and/or EMBA	Location of BIA
Cape gannet (*Morus capensis*)	No threat listing	Breeding KNOWN to occur within EMBA	No BIA
Yellow wagtail (*Motacilla flava*)	No threat listing	Species or species habitat KNOWN occur within EMBA overfly marine area	No BIA
Satin flycatcher (*Myiagra cyanoleuca*)	No threat listing	Breeding KNOWN to occur within EMBA overfly marine area	No BIA
Orange-bellied parrot (*Neophema chrysogaster*)	Critically endangered	Breeding KNOWN to occur within EMBA overfly marine area	No BIA
Blue-winged parrot (*Neophema chrysostoma*)	No threat listing	Species or species habitat KNOWN occur within EMBA overfly marine area	No BIA
Litter curlew (*Numernius minutus*)	No threat listing	Roosting LIKELY to occur within EMBA overfly marine area	No BIA
Ruff (*Philomachus pugnax*)	No threat listing	Roosting KNOWN to occur within EMBA overfly marine area	No BIA
Grey plover (*Pluvialis squatarola*)	No threat listing	Roosting KNOWN to occur within EMBA overfly marine area	No BIA
Great-winged petrel (*Pterodroma macroptera*)	No threat listing	LIKELY to occur in EMBA Foraging, feeding or related behaviour KNOWN to occur within EMBA	Foraging BIA in EMBA
Red-necked avocet (*Recurvirostra novaehollandiae*)	No threat listing	Roosting KNOWN to occur within EMBA overfly marine area	No BIA
Rufous fantail (*Rhipidura rufifrons*)	No threat listing	Species or species habitat KNOWN occur within EMBA overfly marine area	No BIA
Australian painted snipe (*Rostrutula benghalensis*)	Endangered	Species or species habitat KNOWN occur within EMBA overfly marine area	No BIA
Great skua (*Catharacta skua*)	No threat listing	Species or species habitat MAY occur within EMBA	No BIA
Australian pratincole (*Stiltia Isabella*)	No threat listing	Roosting KNOWN to occur within EMBA overfly marine area	No BIA
Spectacled monarch (*Monarcha trivirgatus*)	No threat listing	Species or species habitat KNOWN occur within EMBA overfly marine area	No BIA
Hooded plover (*Thinornis rubricollis*)	No threat listing	Species or species habitat KNOWN occur within EMBA overfly marine area	No BIA
Wood sandpiper (*Tringa glareola*)	No threat listing	Roosting KNOWN to occur within EMBA overfly marine area	No BIA
Common greenshank (*Tringa nebularia*)	No threat listing	Species or species habitat KNOWN occur within EMBA overfly marine area	No BIA
Marsh sandpiper (*Tringa stagnatilis*)	No threat listing	Roosting KNOWN to occur within EMBA overfly marine area	No BIA
Terek sandpiper (*Xenus cinereus*)	No threat listing	Roosting KNOWN to occur within EMBA overfly marine area	No BIA
Little penguin	No threat listing	KNOWN to occur in EMBA	Foraging and breeding BIAs in EMBA

Name	Threat Category	Presence in OA and/or EMBA	Location of BIA
Wilson's storm petrel (*Oceanites oceanites*)	No threat listing	KNOWN to occur in EMBA	Migration BIA in EMBA
Black-faced cormorant (*Phalacrocorax fuscescens*)	No threat listing	KNOWN to occur in EMBA	Foraging and breeding BIAs in EMBA
Black petrel (*Procellaria parkinsoni*)	No threat listing	LIKELY to occur in EMBA	Foraging BIA in EMBA
White-fronted tern (*Sterna striata*)	No threat listing	KNOWN to occur in EMBA	Foraging BIA in EMBA
Crested tern (*Thalasseus bergii*)	No threat listing	LIKELY to occur in EMBA	Foraging BIA in EMBA

Note: this table only includes those species that are classed as seabirds (i.e. spend the majority of their lifecycle over marine waters) or which have been identified as present based on their presence within the EMBA overfly marine area.

Table 31 Seabird BIAs of Relevance to the OA and EMBA

Species	BIA type	Relevance to OA	Relevance to EMBA
Wedge-tailed shearwater	Foraging (x2)	Overlap	Overlap
	Breeding	65 km N of OA	Overlap
Short-tailed shearwater	Foraging (x3)	Overlap	Overlap
	Breeding (x89)	40 km E of OA	Overlap
Wandering albatross	Foraging (x2)	Overlap	Overlap
Antipodean albatross	Foraging (x2)	Overlap	Overlap
Australasian gannet	Foraging (x4)	Overlap	Overlap
	Aggregation (x7)	39 km N of OA	Overlap
White-faced storm-petrel	Foraging (x3)	Overlap	Overlap
	Breeding (x12)	99 km E of OA	Overlap
Common diving-petrel	Foraging	Overlap	Overlap
	Breeding (x16)	45 km N of OA	Overlap
Bullers albatross	Foraging	Overlap	Overlap
Shy albatross	Foraging	Overlap	Overlap
	Breeding	89 km E of OA	Overlap
Indian yellow-nosed albatross	Foraging (x2)	Overlap	Overlap
	Foraging likely	495 km SE of OA	Overlap
Black-browed albatross	Foraging (x2)	Overlap	Overlap
Campbell albatross	Foraging (x2)	Overlap	Overlap
Flesh-footed shearwater	Foraging	713 km NE of OA	Overlap
Sooty shearwater	Foraging (x3)	240 km SE of OA	Overlap
	Breeding (x2)	342 km SE of OA	Overlap
Little penguin	Foraging (x17)	44 km E of OA	Overlap
	Breeding (x39)	50 km E of OA	Overlap

Species	BIA type	Relevance to OA	Relevance to EMBA
Southern giant petrel	Foraging	716 km NE of OA	Overlap
Northern giant petrel	Foraging	716 km NE of OA	Overlap
Wilson's storm petrel	Migration	716 km NE of OA	Overlap
Black-faced cormorant	Foraging (x10)	44 km E of OA	Overlap
	Breeding (x16)	50 km E of OA	Overlap
Black petrel	Foraging	716 km NE of OA	Overlap
Great-winged petrel	Foraging	716 km NE of OA	Overlap
Soft-plumaged petrel	Foraging	80 km SE of OA	Overlap
	Breeding	342 km SE of OA	Overlap
White-fronted tern	Foraging	368 km E of OA	Overlap
White-capped albatross	Foraging	716 km NE of OA	Overlap
Crested tern	Foraging	697 km NE of OA	Overlap

Note: Where several BIAs exist for each species and for the same BIA type, the distance provided represents the closest BIA of that type to the OA.

4.5.8 Conservation Management Plans

Species Recovery Plans set out the research and management actions necessary to stop the decline of, and support the recovery of, listed threatened ecological communities. Recovery plans are enacted under the EPBC Act and remain in force until the species is removed from the threatened list. Conservation advice provides guidance on immediate recovery and threat abatement activities that can be undertaken to ensure the conservation of a newly listed species or ecological community.

Based on the characterisation of the biological environment provided in **Section 4.5**, a summary of the EPBC Act Conservation Management Plans, Recovery Plans and Conservation Advice that relate to species with the potential to occur within the OA are described in **Table 32**. In addition, any relevant measure contained within the conservation advice and recovery plans has been considered as part of the assessment of impacts and risks that may occur as a result of the Seismic Survey (**Section 7** – **Section 9**). The Otway Basin 3D MC MSS will be conducted in a manner consistent with conservation advice and recovery plans for species with the potential to be present in the OA.

Table 32 EPBC Act Conservation Management Plans, Recovery Plans and Conservation Advice relevant to the Otway Basin 3D MC MSS

Common Name	Recovery Plan / Conservation Advice	Threats identified as relevant to the Activity	Requirements relevant to the Otway Basin 3D MC MSS
Bony fish and elasmobranchs			
White shark	Recovery plan for the White Shark (*Carcharodon carcharias*)	Ecosystem effects as a result of habitat modification and climate change	Implement measures to reduce adverse impacts of habitat degradation and/or modification.
Spotted Handfish	Approved conservation advice for *Brachionichthys hirsutus* (Spotted Handfish) Recovery Plan for Three Handfish Species	Habitat degradation (pollution)	Ensure there is no disturbance in areas where spotted handfish occur. Manage any changes to hydrology that may result in increased sedimentation or pollution.
Ziebella Handfish	Recovery Plan for Three Handfish Species	Habitat degradation (pollution)	Ensure there is no disturbance in areas where spotted handfish occur. Manage any changes to hydrology that may result in increased sedimentation or pollution
Red Handfish	Approved conservation advice for *Thymichthys politus* (Red Handfish) Recovery Plan for Three Handfish Species	Habitat degradation (pollution)	Ensure there is no disturbance in areas where spotted handfish occur. Prevent changes to hydrology that may result in increased sedimentation or pollution.
Black Rockcod	Approved conservation advice for *Epinephelus daemelli* (black cod)	No relevant threats listed	N/A.
Australian Grayling	Conservation advice *Protroctes maraena* (Australian Grayling). National recovery plan for Australian Grayling (*Prototroctes maraena*)	Habitat loss and fragmentation Altered hydrology Poor water quality	Protect key habitat areas used by Australian Grayling.
Eastern Gemfish	Commonwealth listing advice on *Rexa solandri*	No relevant threats listed	N/A.
Grey Nurse Shark	Recovery plan for the Grey Nurse Shark (*Carcharias taurus*)	Habitat modification and pollution	Ensure protection at key aggregation sites and BIAs.

Common Name	Recovery Plan / Conservation Advice	Threats identified as relevant to the Activity	Requirements relevant to the Otway Basin 3D MC MSS
Whale Shark	Conservation Advice *Rhincodon typus*, whale shark	Habitat disruption from mineral exploration	Minimise offshore developments.
Maugean Skate	Approved Conservation advice for *Raja* sp.L (Maugen Skate)	Habitat loss, disturbance and modification	Manage any changes to hydrology that may result in pollution.
Marine invertebrates			
Tasmanian Live-bearing Seastar	Approved conservation advice for *Patiriella vivipara* (Tasmanian live-bearing seastar)	Habitat degradation and modification through pollution	Ensure infrastructure or development activities do not adversely impact on known populations.
Marine mammals			
Sei whale	Approved Conservation Advice for *Balaenoptera borealis* (sei whale)	Pollution (persistent toxic pollutants)	Implement measures to manage and reduce, where possible, waste generation.
		Vessel strike	Ensure all vessel strike incidents are reported in the National Vessel Strike Database.
		Anthropogenic noise and acoustic disturbance	All seismic surveys must be undertaken consistent with Part A of the EPBC Act Policy Statement 2.1.
		Habitat degradation including pollution (increasing port expansion and coastal development)	Implement measures to reduce adverse impacts of habitat degradation and/or modification.
Blue whale	Blue Whale Conservation Management Plan 2015 - 2025	Noise interference	Anthropogenic noise in BIAs will be managed such that any blue whale continues to utilise the area without injury, and is not displaced from a foraging area. EPBC Act Policy Statement 2.1 is applied to all seismic surveys.
		Habitat modification	Implement measures to reduce adverse impacts of habitat degradation and/or modification.

Common Name	Recovery Plan / Conservation Advice	Threats identified as relevant to the Activity	Requirements relevant to the Otway Basin 3D MC MSS
		Vessel disturbance	Ensure all vessel strike incidents are reported in the National Ship Strike Database. Ensure the risk of vessel strikes on blue whales is considered when assessing actions that increase vessel traffic in areas where blue whales occur and, if required, implement appropriate mitigation measures.
Southern right whale	Conservation Management Plan for the Southern Right Whale 2011-2021	Noise interference	Minimise the risk of acoustic injury to whales in the vicinity of seismic survey operations. Minimise the risk of biological consequences from acoustic disturbance from seismic survey sources to whales in biologically important habitat areas or during critical behaviours. All seismic surveys must be undertaken consistent with Part A of the EPBC Act Policy Statement 2.1.
		Vessel disturbance	Implement measures to reduce and, where possible, eliminate chronic disturbance leading to increased energetic costs or disruption of critical social behaviours to individual whales as a result of avoidance of vessels. Ensure all vessel strike incidents are reported in the National Vessel Strike Database.
		Entanglement (marine debris)	Reduce and, where possible, eliminate any adverse impacts of marine debris.
		Habitat modification	Implement measures to reduce adverse impacts of habitat degradation and/or modification.
Fin whale	Approved Conservation Advice for *Balaenoptera physalus* (fin whale)	Pollution (persistent toxic pollutants)	Implement measures to manage and reduce, where possible waste generation. Reduce and, where possible, eliminate any adverse impacts of marine debris.
		Vessel strike	Ensure all vessel strike incidents are reported in the National Vessel Strike Database.
		Anthropogenic noise and acoustic disturbance	All seismic surveys must be undertaken consistent with Part A of the EPBC Act Policy Statement 2.1.
		Habitat degradation	Implement measures to reduce adverse impacts of habitat degradation and/or modification.

Common Name	Recovery Plan / Conservation Advice	Threats identified as relevant to the Activity	Requirements relevant to the Otway Basin 3D MC MSS
Southern Elephant Seal	Conservation advice for the southern elephant seal (*Mirounga leoina)*	Pollution	Adapt management actions to reduce disturbance and pollution impacts of southern elephant seals and their important breeding, foraging and resting habitats.
Australian sea lion	Recovery Plan for the Australian sea lion (*Neophoca cinerea*) Issues paper for the Australian sea lion (*Neophoca cinerea*) Conservation Advice *Neophoca cinerea* (Australian sea lion)	Entanglement (marine debris) / ingestion of plastic	Reduce and, where possible, eliminate any adverse impacts of marine debris.
		Habitat degradation / marine pollution (Inc. fuel oil spills)	Implement measures to reduce adverse impacts of habitat degradation and/or modification. Implement measures to manage and reduce, where possible, waste generation.
		Noise interference	Minimise the risk of acoustic injury to sea lions in the vicinity of seismic survey operations.
Marine reptiles			
Loggerhead Turtle	Recovery plan for marine turtles in Australia 2017 – 2027	Deteriorating water quality	Implement measures to manage and reduce, where possible waste generation.
Green Turtle		Marine debris	Reduce and, where possible, eliminate any adverse impacts of marine debris on marine turtles.
Leatherback Turtle		Light pollution	Manage artificial light from onshore and offshore sources to ensure biologically important behaviours of nesting adults and emerging/dispersing hatchlings can continue.
Flatback turtle		Vessel disturbance	Manage activities to ensure marine turtles are not displaced from identified Habitat Critical to the survival and BIAs.
Hawksbill Turtle		Noise interference	A precautionary approach should be applied to seismic work, such that surveys planned to occur inside important internesting habitat should be scheduled outside the nesting season. Seismic surveys must undertake soft starts during surveys irrespective of location and time of year to protect marine turtles.

Common Name	Recovery Plan / Conservation Advice	Threats identified as relevant to the Activity	Requirements relevant to the Otway Basin 3D MC MSS
Seabirds and migratory shorebirds			
Orange-bellied Parrot	National Recovery Plan for the orange-bellied parrot	Barriers to migration and movement (light disturbance)	Manage artificial light from onshore and offshore sources to ensure biologically important migratory behaviours can continue.
Red Knot	Approved Conservation Advice for *Calidris canutus* (Red knot)	Pollution/contamination impacts	Implement measures to manage and reduce, where possible, waste generation.
		Disturbance	Manage disturbance at important sites when red knots are present.
		Habitat loss and degradation	Implement measures to reduce adverse impacts of habitat degradation and/or modification.
Curlew Sandpiper	Approved Conservation Advice for *Calidris ferruginea* (Curlew Sandpiper)	Habitat loss and degradation from pollution	Manage disturbance at important sites when curlew sandpipers are present. Implement measures to reduce adverse impacts of habitat degradation and/or modification.
Eastern Curlew	Approved Conservation Advice for *Numenius madagascariensis* (Eastern Curlew)	Habitat loss and degradation from pollution	Manage disturbance at important sites when eastern curlews are present. Implement measures to reduce adverse impacts of habitat degradation and/or modification.
Australian Fairy Tern	Approved Conservation Advice for *Sternula nereis* (Australian fairy tern) National Recovery Plan for the Australian Fairy Tern (*Sternula nereis*)	Habitat loss, disturbance and modification from pollution	Manage disturbance at important sites when Australian fairy terns are present. Implement measures to reduce adverse impacts of habitat degradation and/or modification.
Flesh-footed Shearwater	Conservation Advice *Ardenna carneipes* (flesh-footed shearwater)	Habitat loss, disturbance and modification	Manage disturbance at important sites when eastern curlews are present. Implement measures to reduce adverse impacts of habitat degradation and/or modification.
		Marine pollution (plastics)	Reduce and, where possible, eliminate any adverse impacts of marine debris on flesh-footed shearwaters.
Shy Albatross	Draft National Recovery Plan for Threatened Albatrosses and Giant Petrels 2021 (CoA 2021a) Conservation Advice *Thalassarche cauta* (shy albatross)	Marine pollution (plastics)	Reduce and, where possible, eliminate any adverse impacts of marine debris on albatrosses.

Common Name	Recovery Plan / Conservation Advice	Threats identified as relevant to the Activity	Requirements relevant to the Otway Basin 3D MC MSS
Grey-headed Albatross	Draft National Recovery Plan for Threatened Albatrosses and Giant Petrels 2021 Approved Conservation Advice for *Thalassarche chrysostoma* (grey-headed albatross)	Marine pollution	Reduce and, where possible, eliminate any adverse impacts of marine debris on albatrosses.
Wandering Albatross Antipodean Albatross Southern Royal Albatross Northern Royal Albatross Sooty Albatross Buller's Albatross Northern Buller's Albatross Black-browed Albatross Campbell Albatross Chatham Albatross Gibson's Albatross Indian Yellow-nosed Albatross Salvin's Albatross Southern Giant Petrel Northern Giant Petrel White-capped Albatross	Draft National Recovery Plan for Threatened Albatrosses and Giant Petrels 2021	Marine pollution	Reduce and, where possible, eliminate any adverse impacts of marine debris on albatrosses.

Common Name	Recovery Plan / Conservation Advice	Threats identified as relevant to the Activity	Requirements relevant to the Otway Basin 3D MC MSS
Soft-plumaged Petrel	Conservation Advice *Pterodroma mollis* (soft-plumaged petrel)	Habitat loss, disturbance and modification from pollution	Manage disturbance at important sites when soft-plumaged petrels are present. Implement measures to reduce adverse impacts of habitat degradation and/or modification.
		Marine pollution	Reduce and, where possible, eliminate any adverse impacts of marine debris on petrels.
White-bellied Storm Petrel	Lorde Howe Island Biodiversity Management Plan	Entanglement in or ingestion of anthropogenic debris	Protect habitat of the White-bellied Storm Petrel
Blue Petrel	Conservation Advice *Halobaena caerulea* (blue petrel)	Habitat loss, disturbance and modification from pollution	Manage disturbance at important sites when blue petrels are present. Implement measures to reduce adverse impacts of habitat degradation and/or modification.
Gould's Petrel	Goulds Petrel (*Pterodroma leucoptera leucoptera*) Recovery Plan	Oceanic oil spills	Manage threats operating at sites where the subspecies occurs.
Fairy Prion (southern)	Conservation Advice *Pachyptila turtur subantarctica* (fairy prion (southern))	Habitat loss, disturbance and modification from pollution	Manage disturbance at important sites when fairy prions (southern) are present. Implement measures to reduce adverse impacts of habitat degradation and/or modification.
Eastern Hooded Plover	Conservation Advice *Thinornis rubricollis rubricollis* (hooded plover (eastern))	Marine pollution and entanglement/ingestion of marine debris	Reduce and, where possible, eliminate any adverse impacts of marine debris on eastern hooded plovers.
Greater Sand Plover	Conservation Advice *Charadrius leschenaultii* Greater sand plover	Habitat loss and degradation Pollution/contamination	Managed disturbance a important sites which are subject to anthropogenic disturbance when greater sand plovers are present
Lesser Sand Plover	Conservation Advice *Charadrius mongolus* Lesser sand plover	Habitat loss and degradation Pollution/contamination	Managed disturbance at important sites which are subject to anthropogenic disturbance when lesser sand plovers are present
Nunivak Bar-tailed Godwit	Conservation Advice *Limosa lapponica baueri* Bar-tailed godwit (western Alaskan)	Habitat loss and degradation Pollution/contamination	Managed disturbance a important sites which are subject to anthropogenic disturbance when lesser sand plovers are present

Common Name	Recovery Plan / Conservation Advice	Threats identified as relevant to the Activity	Requirements relevant to the Otway Basin 3D MC MSS
Australian Painted Snipe	Approved Conservation Advice for *Rostratula australis* (Australian painted snipe)	Habitat loss, disturbance and modification	Manage any changes to hydrology that may result in pollution
Great Knot	Conservation Advice *Calidris tenuirostriss* Great knot	Habitat loss and degradation	Managed disturbance at important sites which are subject to anthropogenic disturbance when lesser great knots are present
		Pollution/contamination	
All migratory shorebirds	Wildlife conservation plan for migratory shorebirds	Anthropogenic disturbance (industrial operations and artificial lighting)	Investigate the significance of cumulative impacts on migratory shorebirds habitat and populations
		Habitat modification (Acute pollution)	Ensure all areas important to migratory shorebirds are considered in development assessment processes
All seabirds	Wildlife Conservation Plan for Seabirds 2022	Habitat modification and anthropogenic disturbance	Identify important habitats for all seabirds during critical life stages; and Manage anthropogenic disturbance to seabird breeding and roosting areas.
		Acute pollution (e.g. oil spills)	
		Light pollution	Enhance contingency plans to prevent and/or respond to environmental emergencies that have an impact on seabirds and their habitats.
		Invasive species	Ensure seabirds are protected from the adverse effects of invasive species.

4.6 Cultural and Heritage Values

Identifying features such as sites of Aboriginal significance and built European heritage is important to ensure cultural and heritage values are protected and preserved. Reliable information about the occurrence and extent of such features is limited or often not readily accessible. However, existing information and databases indicate they are predominantly terrestrial or constrained to the shoreline and coastal margins and fall within the State's jurisdiction.

The cultural and heritage properties of the OA and surrounding EMBA are considered below.

4.6.1 Aboriginal Heritage

Indigenous Australian people have a strong continuing connection with Land and Sea Country that extends back some 50,000 years. Across Australia, Indigenous people have been sustainably using and managing their Sea Country throughout this period. Sea Country is valued for Indigenous cultural identity, health and wellbeing. A preliminary search of the relevant state Aboriginal Heritage databases[4] was undertaken to assess the potential for Aboriginal sites or artefacts of significance to occur within the OA.

Sites of Aboriginal significance, and known sites of artefacts and archaeological significance, are largely constrained to the shoreline and near shore limits, within state coastal waters. The OA ranges from 35 km offshore from Portland to 57 km offshore from Otway, information currently displayed on the VIC Aboriginal Cultural Heritage Register and Information System (**ACHRIS**) public map indicates sites of are located across the shoreline, and do not extend offshore locations occupied by the OA. Similarly, the TAS Aboriginal Heritage Register indicates over 13,000 known places and objects of significance are listed on the register, and includes heritage sites of shell middens, stone artefacts, and possibly burial sites, rock shelters and stone arrangements (AHR, accessed May 2023). To this end, Aboriginal Heritage sites extend predominantly along the VIC coastline within the northern and north-eastern boundary of the EMBA, and along the western coastline of TAS, at the eastern extent of the EMBA. Given the EMBA reflects a coarse spatial footprint of impacts associated with an unplanned event (i.e. shoreline accumulation of hydrocarbons, in the event of a fuel oil spill), and the low likelihood of occurrence, these sites are not predicted to be impacted.

4.6.1.1 Native Title

Native Title is the recognition that Aboriginal and Torres Strait Islander people have rights and interests to land and waters according to their traditional law and customs. As set out in Australian Law, Native title is governed by the *Native Title Act 1993* (Cth). In accordance with the *Native Title Act 1993,* non-exclusive Native Title can exist offshore within the limits of Australia's territorial sea (12 NM), meaning that native titleholders will not have the right to exclude others from accessing the sea or seabed in the waters where native title exists.

A search of the National Native Title Tribunal Register[5] did not identify any Native Title areas or any pending titles within the OA.

Victoria https://achris.vic.gov.au/#/onlinemap
New South Wales https://www.environment.nsw.gov.au/topics/heritage/search-heritage-databases/aboriginal-heritage-information-management-system
Tasmania https://www.aboriginalheritage.tas.gov.au/cultural-heritage
[5] National Native Title Register, accessed 26 March:
http://www.nntt.gov.au/searchRegApps/NativeTitleRegisters/Pages/Search-National-Native-Title-Register.aspx

Native Title Determination Areas that are consented or under application, that intersect or are in close proximity to the boundary of the EMBA are listed in **Table 33**. Three Native Title Determination Consent Areas are registered at VIC coastline locations shown to include the extent of the coastline EMBA, two Native Title Determination areas were identified that are in close proximity to the nearshore coastal edge of the EMBA (South Australia and VIC), and four areas were identified that are currently subject to application processes (active cases), but were also identified as being in contact with the coastal edge of the EMBA or in close proximity to the offshore edge of the EMBA. Two areas in VIC (Boonwurrung People, Gunditjmara Area C) were assessed as Not Accepted for Registration and are not included in **Table 33**.

The NNTR search did not display any areas under application or with active cases in TAS, despite the current presence of Traditional Owner Groups (**Section 5**).

Table 33 Native Title Determination Consent Areas and areas under current application (Accepted for Registration status) intersecting or in close proximity with the EMBA

Tribunal File No. Federal Court File No. / Determination or Date Accepted for Registration	State/Territory/ Description	Short Name / Registered Native Title Body Corporate
South Australia		
TFN: SCD2017/002 FCF: SAD6027/1998 Date Determined: 14/12/2017	South Australia. Coastal boundary extending from the Coorong at Mill Lake, northwards to Cape Jervis. Native Title Determination Area does not have direct contact with the EMBA boundary, but is in close proximity.	Ngarrindjeri and Others Native Title Claim RNTBC: Ngarrindjeri Aboriginal Corporation RNTBC
TFN: SC1998/004 FCF: SAD6027/1998 Accepted for Registration: 28/10/2016	South Australia.	Ngarrindjeri and Others Native Title Claim RNTBC: Ngarrindjeri Aboriginal Corporation RNTBC
SC2017/002 SAD211/2017 Accepted for Registration: 10/11/2017	South East South Australia near the VIC border, extending north-west to Tilley Swamp, Coorong National Park. EMBA boundary coincides with shoreline/coastal edge of the application area close to the VIC border.	First Nations of the South East #1 RNTBC: To be confirmed pending assessment of registration
Victoria		
TFN: VCD2007/001 FCF: VID6004/1998, VID655/2006 Date Determined: 30/03/2007	VIC. Eumerella (Yumbuk) Coastal Reserve (in line with Boundary Rd , Tyrendarra East), extending to Oxbow Lake entrance, next to SA border Native Title Determination Area has shoreline contact with outer edge of the EMBA.	Gunditjmara - Part A RNTBC: Gunditj Mirring Traditional Owners Aboriginal Corporation RNTBC

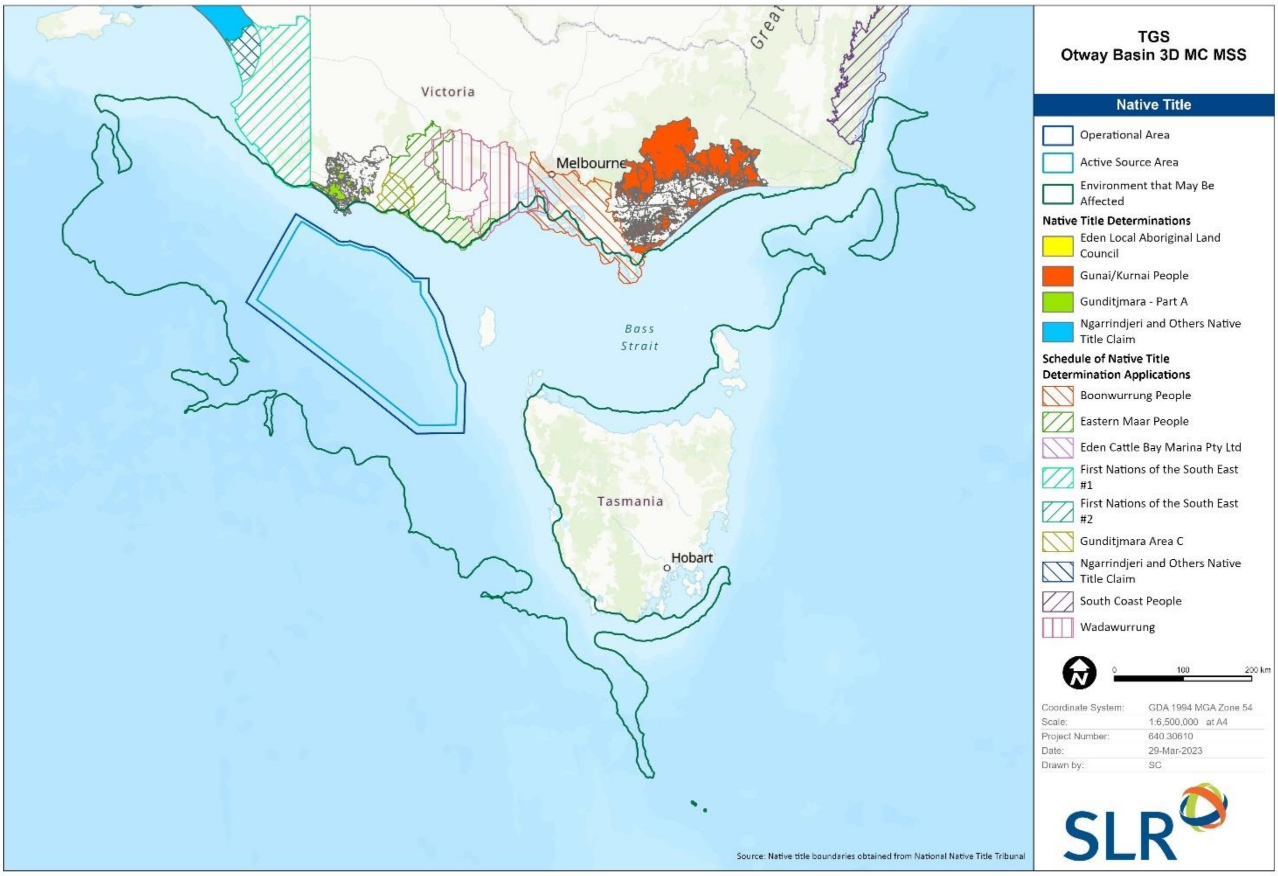
TFN: VCD2011/001 FCF: VID6004/1998, VID655/2006 Date Determined: 27/07/2011	VIC. Lady Julia Percy Island; Eumerella (Yumbuk) Coastal Reserve , extending west to be in line with Boundary Rd , Tyrendarra East Native Title Determination Area has shoreline contact with outer edge of the EMBA.	Gunditjmara & Eastern Maar RNTBC: Gunditj Mirring Traditional Owners Aboriginal Corporation RNTBC, Eastern Maar Aboriginal Corporation RNTBC
TFN: VCD2010/001 FCF: VID6007/1998, VID482/2009 Date Determined: 22/10/2010	VIC. Corner Inlet/Wilson Promontory National Park to opposite Marlo Coastal Reserve, mouth of the Snowy River. EMBA does not extend to shoreline, but is in close proximity.	Gunai/Kurnai People RNTBC: Gunaikurnai Land & Waters Aboriginal Corporation RNTBC
TFN: VC2012/001 FCF: VID21/2019 *Date Determined 28/03/2023[#]	Yambuk, extending east to Aireys Inlet along the coast. EMBA intersects with the coastal southern boundary of the application area.	Eastern Maar People Eastern Maar Aboriginal Corporation RNTBC
TFN: VC2022/002 FCF: VID693/2022 *Currently identified for Registration Decision (new decision in progress)	Wongarra coastline, extending easterly to Point Lonsdale, including Swan Island. Seaward extent of the application area intersects with the EMBA.	Wadawurrung RNTBC: To be confirmed pending assessment of registration
New South Wales		
TFN: NC2017/003 FCF: NSD1331/2017 *Accepted for registration 31/01/2018	Seaward of Edrom, extending north to Cuttagee. Seaward extent of the application area adjacent to the eastern extent of the EBMA.	South Coast People RNTBC: To be confirmed pending assessment of registration

[#] As reported in the media (*The Age* online and *ABC News*, 28 March 2023) as being Determined as Native Title. Pending NNTT website update.



Note- The Eastern Maar area was announced as Native Title Determination on 28 March 2023, updated data files showing the Determined Area from NNTTR are pending.

Figure 45 Native Title Determination Areas

4.6.1.2 Traditional Use

Indigenous occupation of coastal areas adjacent to the SEMR dates back at least 40,000 years (CoA, 2015). Historically, Indigenous peoples in the SEMR fished and collected shellfish, and seals and mutton birds were reported as important food sources. In some places along the VIC coastline there is evidence of nodules of marine chert (a kind of flint) which were washed ashore and provided raw material for stone tools. In the Coorong area of South Australia, mesh nets, woven fish traps, spears and canoes were developed to exploit marine resources (CoA, 2015). Thus, Indigenous peoples' connections with 'Sea Country' are regarded as equally important as connections with the land (CoA, 2015). Indigenous communities of the SEMR continue to have a strong cultural and spiritual connection to the ocean and to use ocean resources for food, traditional purposes, and income.

Sea Country is of particular importance for this EP, as the EMBA may extend into areas of known Sea Country. Sea Country is all estuaries, beaches, bays, and marine areas collectively, within a traditional estate. Sea Country contains evidence of the ancient mystical events by which all geographic features, animals, plants, and people were created. Sea Country contains sacred sites and contains tracks (or song lines) along which mythological beings travelled during the creation period (Smyth and Isherwood, 2016).

Indigenous peoples use and actively manage the coastal and marine environments of the region as a resource and to maintain cultural identity, health, and wellbeing, including within conservation areas such as Commonwealth, Australian and State Marine Parks. It is recognised that spiritual corridors extend from terrestrial areas into nearshore and offshore waters, that many marine animals are totems for Indigenous people, and that songlines pass through marine parks (CoA, 2015). The maintenance of culture and heritage through ritual, stories and traditional knowledge continue to be important uses of Land and Sea Country (CoA, 2015).

Aboriginal people's physical relationship with offshore waters was historically based on travel to islands, and the use and management of coastal species that are part of ocean ecosystems. The relationship between Indigenous people and the SEMR began when sea levels were much lower – a land bridge (Bass Strait) allowed movement of people between "mainland" Australia and TAS, and local Indigenous people were able to harvest species and utilise parts of the region that are now covered by deeper offshore waters (CoA, 2015). As sea levels rose with the end of the most recent ice age (ca 13,000 years ago) the land bridge became inundated. Current sea levels stabilised ca 5,000 years ago, isolating TAS from the mainland (National Oceans Office, 2002).

The OA does not include submerged islands or the submerged land bridge between the mainland and TAS (Bass Strait), however, TGS acknowledges Traditional Owners' Sea Country and a wider spiritual connection, and connection between Indigenous people, land, sea and resources. TGS also understands that while marine resources used by Indigenous people are generally limited to coastal waters for activities such as fishing, hunting and maintenance of culture and heritage, many Aboriginal groups, through their Sea Country relationships, have a direct interest in decisions affecting the management of deeper offshore waters.

The Traditional Owners of Country adjacent to the OA include the Buandig People whose Country includes the coastal area from the south of Robe to the area around the mouth of the Glenelg River at Nelson, VIC (AIATSIS, 2023). The Gunditjmara people are the traditional owners of the coastal area extending from Portland in the south, Port Fairy, Warrnambool and inland into Camperdown (Gunditjmara Aboriginal Cooperative Limited, 2022; AIATSIS, 2023). The Eastern Maar are Traditional Owners of south-western VIC, their land encompassing Warrnambool, Port Fairy, and the Great Ocean Road areas, stretching 100 m out to sea from low tide (Eastern Maar Aboriginal Corporation, 2020). The Peerapper (North West Tribe) of the Palawa people are the Traditional Owners of Lutruwita (TAS) (AIATSIS, 2023).

A review of the publicly available information on VIC and TAS Aboriginal cultural heritage databases confirm that there are no known indigenous heritage sites within the OA. Indigenous heritage and archaeological sites occur in coastal areas throughout the wider EMBA. Site specific characteristics and exact locations are not individually identified here. General area descriptions (e.g. as per the Victorian Aboriginal Cultural Heritage Register and Information System) demonstrate sites are located along the entire VIC coastline. It is assumed similar coastal distribution extends to South Australia, NSW and across the TAS coastline in contact with the EMBA.

Indigenous Protected Areas[6] (**IPAs**) are recognised areas of Land and Sea Country managed by Indigenous groups in accordance with Traditional Owners' objectives to deliver biodiversity conservation outcomes for the benefit of all Australians. The National Indigenous Australians Agency (**NIAA**) online register[3] was reviewed to identify IPAs that may be located within the EMBA. IPAs located within the EMBA are identified as:

- Deen Maar IPA (VIC), including Deen Maar Island (Lady Julia Percy Island), has a strong spiritual and visual connection with the Traditional Owners as the place where Bunjil, the Creator, left this world (NIAA website, accessed March 2023);

[6] https://www.niaa.gov.au/indigenous-affairs/environment/indigenous-protected-areas-ipas

- Preminghana IPA (TAS) protects historic Aboriginal engraving sites and the endangered Preminghana daisy;
- Badger Island IPA and Mount Chappell Island IPA (TAS) are located just outside the EMBA, off Flinders Island.

4.6.2 European and Marine Heritage

The coastline, reefs, and seabed of the State waters adjacent to the SEMR are the resting places of many shipwrecks, including wooden sailing ships, early whaling ships, passenger ships and fishing vessels (CoA, 2015). Hundreds of shipwrecks have been recorded in the waters of south-eastern Australia. Historic shipwrecks, sunken aircraft and associated relics are recognised and protected under the Underwater Cultural Heritage Act 2018. Under the act, all wrecks and sunken aircraft more than 75 years old are protected, together with their associated relics regardless of whether their actual locations are known. The Commonwealth Minister responsible for the environment can also make a declaration to protect any historically significant wrecks or artifacts and relics that are less than 75 years old.

A search of the Australasian Underwater Cultural Heritage Database (DoCCEEW online[7]) indicates that there are four known historic shipwrecks in the OA (**Table 34**, **Figure 46**). There are no known sunken aircraft within the OA identified on the database. Four Underwater Cultural Heritage Protected Zones are identified along the northeastern extent of the EMBA, along the VIC coastline. These include: SS Alert (1893), Clonmel (1841), SS Glenelg (1900), and SS Federal (1901) (DoCCEEW online)

Throughout the EMBA, lighthouses also constitute a major part of southern Australia's marine cultural heritage (CoA, 2015). The first commercial fishing ventures of European settlers focused of harvesting seals and whales (CoA, 2015). Within the EMBA, whaling stations were set up at places such as Portland, Port Fairy in VIC, Victor Harbour in South Australia, and Recherche Bay and Southport in TAS (CoA, 2015). The Davidson Whaling Station near Eden, NSW, at the most easterly extent of the EMBA is considered by some as one of the first industrial complexes in Australia.

Seventeen State protected Heritage Sites/Rivers/Agreements were identified within the EMBA within the EPBC Act Protected Matters Report. This includes nine Heritage Agreements (all in South Australia), five historic sites (all in TAS), and three Heritage Rivers (within VIC) (**Table 35**)

Table 34 Historic Shipwrecks Located within the Operational Area

Vessel Name	Vessel Type	Date Wrecked	Wreck Location
Tubal Cain	Unknown	1862	200 miles W.S.W of Cape Otway
Freak	Sailing	1834	N.W. coast of TAS
British Admiral	Sailing	1874	British Admiral Reef, King Island
John Ormerod	Unknown	1861	Discovery Bay, 30 miles W. of Portland

[7] https://www.dcceew.gov.au/parks-heritage/heritage/underwater-heritage/auchd

Table 35 Heritage Rivers and Historic Sites Identified within the EMBA (Heritage Agreements in South Australia not listed)

State	Reserve Type	Protected Area Name
Victoria	Heritage River	Bemm, Goolengook, Arte and Errinundra Rivers
Victoria	Heritage River	Aire River
Victoria	Heritage River	Glenelg River
Tasmania	Historic Site	Strahan Customs House
Tasmania	Historic Site	D'Entrecasteaux Watering Place
Tasmania	Historic Site	Cape Sorell
Tasmania	Historic Site	Currie Lightkeepers Residence
Tasmania	Historic Site	Macquarie Harbour

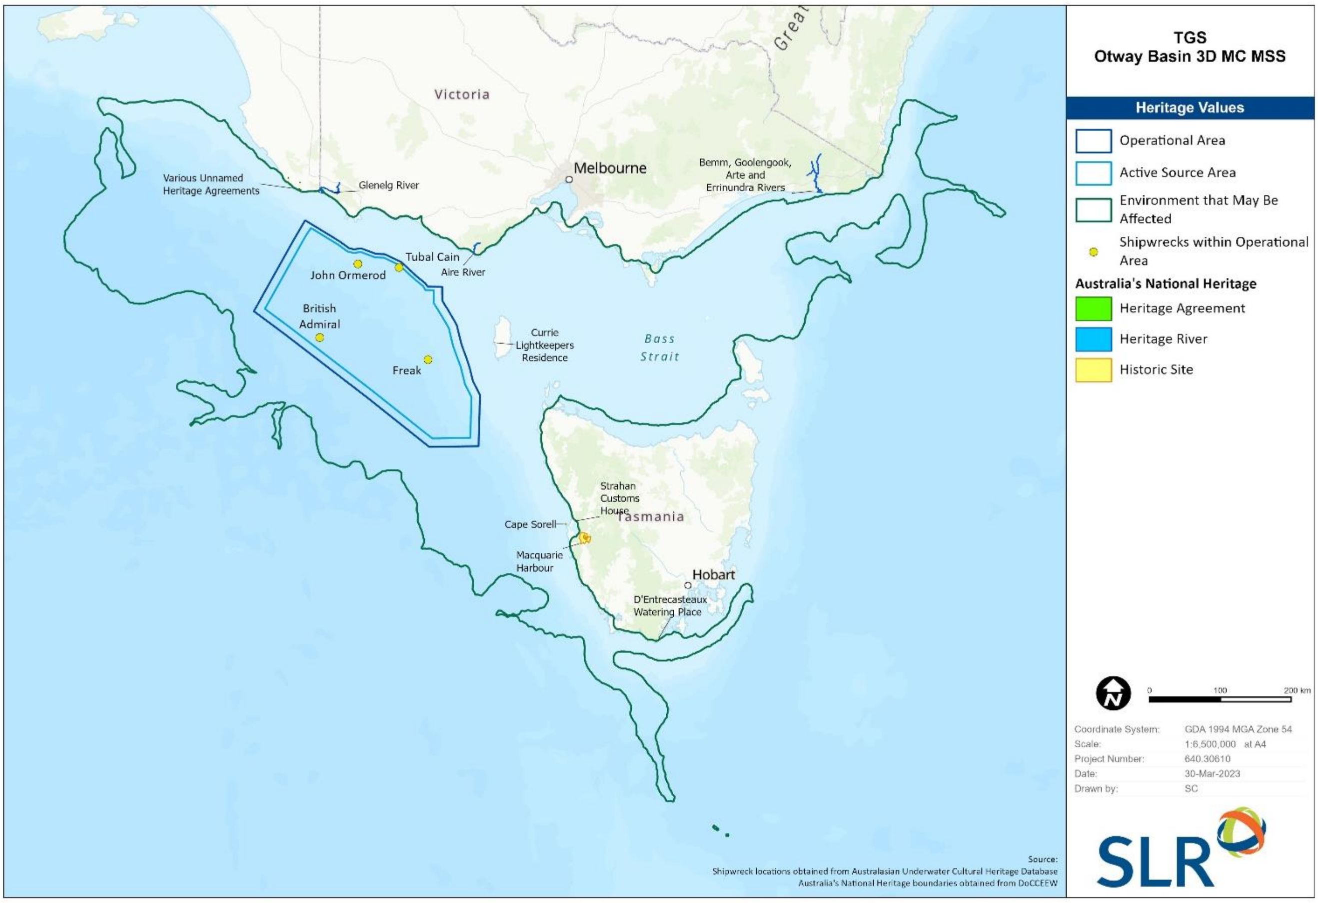


Figure 46 Places of Marine Heritage including Shipwrecks and Aircraft Wrecks

4.7 Socio-Economic Environment

4.7.1 Coastal Settlements

Coastal settlements and urban centres (as defined by the Australian Bureau of Statistics) are spread across most the entire extent of the EMBA across the mainland from South Australia to the eastern boundary of VIC and NSW.

In the southern area of South Australia within the EMBA, Port MacDonnell is a small urban centre close to the VIC border. Further northwest in South Australia, Southend is coastal urban centre located at the northern extent of Canunda National Park, but not within the EMBA boundary itself.

Across the VIC coast, coastal urban centres include Portland, Port Fairy, Warrnambool, Peterborouh and Port Campbell all to the west of Otway. To the east includes Marengo, Apollo Bay, Lorne, Aireys Inlet, Anglesea, Jan Juc, Torquay, Barwon Heads, Point Londsdale, St Leonards and Portarlington within the defined EMBA. East of the Mornington Peninsular towards Wilsons Promontory, coastal urban centres include Cape Schank, Flinders, Phillip Island, San Remo, Kilcunda, Cape Patterson, Inverloch, Venus Bay and Sandy Point. Further east from Wilsons Promontory, coastal urban centres include Golden Beach/Paradise Beach, Lakes Entrance, Lake Tyers Beach, Marlo, and Mallacoota in close proximity to the northeastern boundary of the EMBA (ABS, 2023).

In TAS (including King Island), coastal urban areas located within the EMBA, or in close proximity include Currie (King Island), and Strahan (Northwest TAS).

Where limited information was available on the extent, population, and socio-economic environment for community settlements, including indigenous community settlements, the precautionary principle has been applied and assumed a direct association with the marine environment. To this end, potential impacts to these coastal settlements has been evaluated and managed through consultation with the nominated State Government and the Traditional Owners Representatives (see **Section 5**).

4.7.2 Tourism and Recreation

The SEMR offers a wide and diverse range of opportunities for marine based tourism and recreational activities, including snorkelling, scuba diving, surfing, kayaking, whale and wildlife watching, sailing and charter boat cruises. Popular tourist destinations include Phillip Island and the Great Ocean Road (VIC), Robe and Beachport (South Australia) and Strahan and the Freycinet Peninsula (TAS) (CoA, 2015).

Marine National Parks or Marine Sanctuaries encompass over 5% of VIC coastal waters, and provide areas for recreational activities including swimming, surfing, snorkelling, scuba diving and boating (Travel Victoria, 2023). Scuba diving on shipwrecks occurs at Apollo Bay, Warrnambool, and Port Campbell. Vessel based sightseeing tours include fur seal tours at Cape Bridgewater and Lady Julia Percy Island, tours of Portland Harbour and Lawrence Rocks, and whale and dolphin cruises around Phillip Island. Land-based whale watching occurs along the Great Ocean Road at Warrnambool and Portland. Phillip Island is also home to the largest little penguin colony in the word, which attracts tourists nightly to watch the 'penguin parade'.

Key locations for tourism in SA include Kangaroo Island, the coasts of the Fleurieu, Yorke and Eyre Peninsulas, offshore islands and the GAB Marine Park. Tourism activities include sailing, swimming, whale and wildlife watching, scuba diving and recreational fishing. Sea lion and dolphin swim tours operate along the coast, including off Kangaroo Island. The Neptune Islands, off Spencer Gulf is renowned for cage diving with great white sharks. Whale watching for migrating humpback and southern right whales is popular at Victor Harbour and in the GAB during the winter months.

The west coast of TAS is largely inaccessible and unpopulated, attracting low numbers of mainly shore-based bushwalkers and fishers. King Island tourism is predominantly centred on walking, surfing, and dining on local fresh produce.

4.7.2.1 Whale Watching

Migration southern right whales and blue whales attract visitors to the VIC coastline from approximately May to early October. The coastline encompassing Portland and Warrnambool offer some of the best shore-based whale watching locations atop cliff tops, rocky outcrops, and purpose-built viewing platforms (Visit Victoria, 2018a). At the southern right whale nursery grounds offshore from Logan's Beach in Warrnambool, whales can be observed from within 100 m of the coastline from viewing platforms (Visit Victoria, 2023a). In Portland, popular viewing locations include off the coast from Cape Bridgewater to Narrawong, Port of Portland and the cliffs above Nuns Beach and Portland Bay (Visit Victoria, 2023a). Blue whales rarely approach land; however, the headlands of Cape Nelson and Cape Bridgewater provide opportunities for viewing blue whales at a distance (Visit Victoria, 2023a). Offshore whale spotting is undertaken from helicopters and light planes, and occasionally vessels.

4.7.2.2 Diving

Recreational diving occurs inshore of the OA, and generally in water depths less than 30 m, concentrating around structures such as piers and shipwrecks, or natural reefs and rocky outcrops. While divers use these areas for sightseeing, many also dive to harvest target species such as abalone and rock lobster when in season. Several dive charters offer guided tours, operating out of ports inshore of the OA.

Despite the often-rough coastal conditions along the Great Ocean Road, several popular shore dive sites can be found including the breakwater and surrounding shipwrecks at Warrnambool, Stingray Bay (part of the Merri Marine Sanctuary), and Middle Island. Pickering and Thunder Point are also popular dive spots and are accessible from shore or boat. Surrounding Port Campbell are several popular dive sites based around shipwrecks, including some sites that are accessible only by boat (Visit Victoria, 2023a).

Visibility in TAS waters ranges from 12 m (summer) to more than 40 m (winter). Popular dive sites on the northwest of the island include Rocky Cape and Boat Harbour, and the many shipwrecks around King Island (Discover Tasmania, 2023a). These dive sites are typically only accessible by boat.

4.7.2.3 Cruise, Sailing and Boating Activity

Recreational boating is popular throughout Australia, with most boating activities occurring in bays and sheltered waters, although open waters are also utilised, including those greater than 5 NM from shore. Most recreational boating activities occur over summer months, with the least amount of boating activity in the cooler winter months (NMSC, 2009). All operators of registered recreational motorboats in SA, VIC, and TAS waters are required to hold a marine licence.

Recreational boat users in SA prefer open waters (NMSC, 2009), with most of the recreational boat use in SA occurring in the Spencer Gulf, Gulf of St Vincent, and around Kangaroo Island.

Boating is one of VICs most popular recreational activities, with over 417,000 VIC residents holding recreational vessel licences and more than one in ten VIC residents regularly participating in recreational boating. Recreational boating in VIC is concentrated at 20 key locations, with Port Phillip and Western Port the most heavily used. Coastal areas Portland, Warrnambool, Torquay, Barwon River, Anderson Inlet, Corner Inlet, and Mallacoota are also in the top 20 boating locations for VIC (the remaining locations are freshwater based) (DoT, 2021). Boating trips are mainly associated with fishing, with a small number of boaters launching for the purpose of touring/cruising. Recreational boating activity peaks from October to April although boating activities also continue throughout the ‘off season’ (May to September) (DOT, 2021).

On a per capital basis, TAS has the highest motorboat ownership across Australia (MAST, 2021). Exposed conditions along the west coast of TAS results in low boating activity, although the use of the marine environment increases around King Island due to shelter provided by the island.

The Melbourne to King Island Ocean Yacht Race between Queenscliff (VIC) and King Island (TAS) is held annually on the second weekend in March. The race starts off in Queenscliff and covers 114 NM to finish in Grassy Harbour, King Island. The race is run by the Ocean Racing Club of Victoria in conjunction with the King Island Boat Club (ORCV, 2023). The Ocean Racing Club of Victoria also runs two races at Christmas; the Melbourne to Hobart (‘Westcoaster’) yacht race which tracks across Bass Strait from Melbourne and along the west and south coasts of Tasmania before finishing in Hobart, and the Melbourne to Devonport yacht race which tracks south across Bass Strait.

4.7.2.4 Surfing

The Limestone Coast (from Kingston to the VIC border) supports heavy surf breaks that are typically only surfed by experienced surfers. Popular surfing areas include Robe, Beachport, Port MacDonnell, Cape Northumberland, Guichen and Rivoli Bays, Southend, Cullens, and Posties (Surfing Atlas, 2023).

Along the Great Ocean Road west of Cape Otway is Johanna Beach; one of the top surfing beaches in VIC. Other valued areas include Princetown, Gibson Steps, Port Campbell, and Peterborough, Lighthouse and Green Island, The Passage, and the reefs as Gabbos and Gooloos (Visit Victoria, 2023b). Further west around Warrnambool popular breaks include Logan’s Beach, The Flume, Levy’s Beach, East Beach, while hot spots for long surf breaks include Shelley beach, the water tower near Portland, Yellow Rock, Crumpets, and Whites Beach (Visit Victoria, 2023b). Although mid-December to mid-January (school holiday period) is the most popular time for surfing along the Great Ocean Road, autumn and winter (March – August) represent the best time of the year for surfing (Wildlife Tours, 2023).

Surfing opportunities along the northwest coast of TAS include challenging waves at Marrawah settlement (Ann Bay, Mawson Bay, and Green Point). Further north on King Island is Martha Lavinia Beach, which contains a unique wave that breaks both left and right and is referred to as ‘the jewel in the crown’. Across TAS, summer periods provide the mildest waves, with bigger waves arriving in winter (Discover Tasmania, 2023b).

4.7.2.5 Recreational Fishing

Recreational fishing is an important activity in Australia both socially and economically, with most recreational fishing occurring in state and territory waters. Recreational fishing in state waters is subject to state-specific rules and regulations including seasonal closures, licence requirements, and catch bag and size limits. Seasonal closures are often established to protect fished species during breeding seasons and may be permanent, seasonal, or temporary (PIRSA, 2022), although not all recreationally fished species are subject to seasonal closures. Recreational fishing clubs are found in each state, many of which run fishing competitions throughout the year.

Although recreational fishing occurs in all coastal waters in South Australia, most of the activity occurs in the Spencer Gulf, Gulf of St Vincent, and surrounding Kangaroo Island to the west of the OA, and at lower intensity along the Limestone Coast. Most recreational fishing is off privately-owned boats followed by land-based fishing off the shore and rocks (rather than off public wharves/jetties) (Giri and Hall, 2015). In a survey of South Australian recreational fishermen, approximately 67% fished within 5 km of the coastline, while approximately 45% utilised offshore waters (> 5 km from shore). In the south-east of South Australia, fishing effort is relatively evenly spread along the coast, with highest effort around Kingston/Robe and lowest effort off the Coorong beaches (Giri and Hall, 2015). Commonly targeted species in SA include blue swimmer crab, King George whiting, Australian herring, pipi, garfish, squid, striped trumpeter, snapper, Australian salmon, mulloway, and scallops, with Australian herring and King George whiting the most caught finfish (Giri and Hall, 2015).

Rock lobsters are also recreationally targeted in SA waters, with fishermen allowed to use drop nets, pots, or SCUBA to take lobsters during the open season (Linnane *et al*., 2018). Abalone are also caught by snorkelling or SCUBA diving (PIRSA, 2012).

VIC has the third highest number of people participating in recreational fishing in Australia, although this is likely a reflection of its relatively large population size (Henry and Lyle, 2003). Port Phillip Bay (northeast of the OA) is the most important embayment in VIC for recreational fishing (Ford and Gilmour, 2013), and is indicative of the species targeted by recreational fishermen throughout VIC waters. More than 62 species are recreationally caught in Port Phillip Bay, including finfish, sharks, and shellfish, with the most targeted species being King George whiting, flathead, snapper, garfish, Australian salmon, and gummy shark (Ford and Gilmour, 2013). Although recreational fishing occurs year-round, Ford and Gilmour (2013) suggest November – April is the peak fishing period based on Port Phillip Bay catch.

Recreational fishing is a popular past time in TAS, with at least 120,000 Tasmanians fishing at least once a year. The west and northwest coast of TAS support comparatively lower levels of recreational fishing than the TAS east coast (Lyle *et al*., 2009). Shore-based fishing along this coast is more prevalent than boat-based fishing. Although most boating effort occurs 5 km or less from shore, some fishermen target waters more than 5 km from shore. The main target species along the TAS west coast are rock lobster, abalone, and trumpeter. Rock lobster catch is predominantly from inshore waters from November to March, with fishing activity peaking immediately following the season opening in November. Offshore fishing targets mid-depth reef associated species such as striped trumpeter, and deepwater shelf-edge associated species such as blue-eye trevella (Tracey *et al*., 2020a). Abalone catch generally occurs during summer and autumn, peaking in December and January (Lyle *et al*., 2009). Game fishing for pelagic sharks (primarily mako shark) also occurs off the northwest coast of TAS over summer months (Tracey *et al*., 2013).

A survey of recreational fishing for southern bluefin tuna in Australia estimated a catch of 270 t in 2018–19 (Tracey *et al*., 2020b), and 5% of Australia's quota allocation for this species is set aside for mortality associated with recreational fishing (Bulman *et al*., 2020). Tuna fishing in TAS waters has generally been restricted to off the east coast (Lyle *et al*., 2009), although waters both east and west of Tasmania may present fishing opportunities year-round. In VIC, tuna are targeted in the offshore waters along the coastline, with southern bluefin tuna the main focus of recreational fishermen and charter operators, including waters on the outer continental shelf (Bulman *et al.,* 2020). While the timing of the tuna season varies on an annual basis, tuna are typically present along the coast from late summer through to early winter, possibly associated with upwelling systems. Tourism activities associated with the tuna industry are particularly important for the town of Portland, VIC, with several charter vessels, as well as privately owned boats, operating out of the town. Engagement with Tuna Australia suggests up to 350 – 400 boats targeting southern bluefin tuna use Portland, Port Fairy, and Warrnambool as staging areas. In February and March 2023, recreational landings of southern bluefin tuna were high at all western VIC ports and in Bass Strait. Landed fish in Bass Strait averaged 20 – 25 kg and were being caught in water depths less than 20 m, and in some cases from the shore (Tuna Australia, 2023).

Charter boats provide a commercial platform for recreational fishing activities and attract valuable income into coastal regions. Fishing charters generally operate from most coastal towns where they target reefs, seagrass meadows, unvegetated soft bottom, sheltered beaches and tidal flat habitats (PIRSA, 2011), while primary target species for charter vessels generally mirrors those that are targeted by recreational fishers. Charter operators are still required to comply with recreational fishing restrictions and prohibitions, such as seasonal closures, minimum and maximum sizes, and catch limits.

4.7.3 Commercial Fisheries

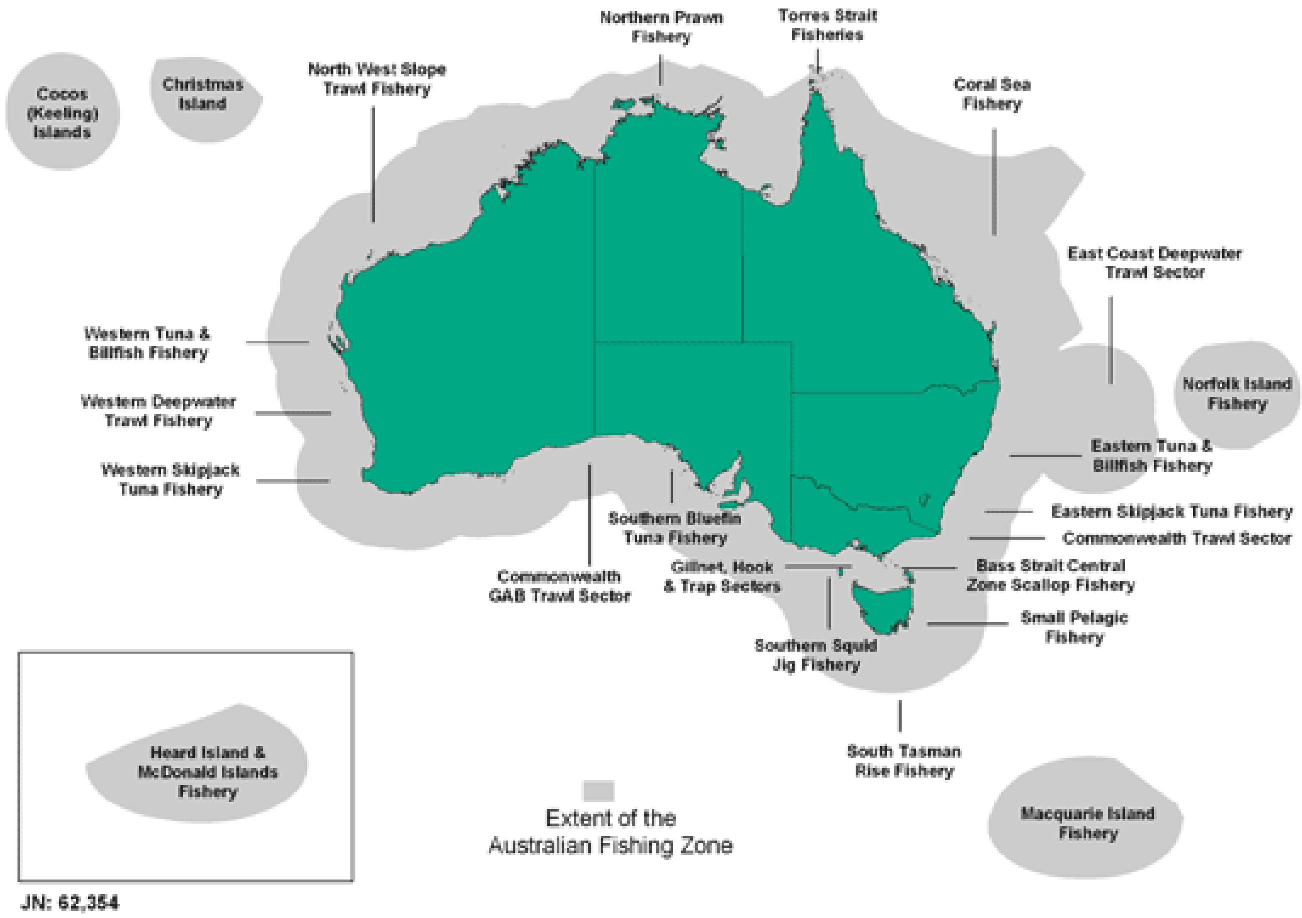
Australia's fisheries are those that occur within the Australian EEZ (waters out to 200 NM from coastal baselines). Boundaries within Australia's fisheries have been established to simplify jurisdiction (DoAWR, 2002). Fisheries are either:

- Commonwealth managed fisheries – those in Commonwealth waters between 3 NM and 200 NM from the coastline. Commonwealth waters are covered by the Australian Fishing Zone (**Figure 47**) (DoAWR, 2023) and are managed through the Australian Fisheries Management Authority (**AFMA**); or
- State managed fisheries – those in inshore waters out to 3 NM. Jurisdiction is vested in the adjacent State or Territory.

Where a fishery falls within multiple jurisdictions, an Offshore Constitutional Settlement arrangement is generally developed, whereby sole responsibility is passed to one jurisdiction. Alternatively, a Joint Authority may be formed, allowing for the co-management of the fishery through the legislation of one jurisdiction (DoAWR, 2002).

Commercial fishing within the OA and EMBA is comprised of Commonwealth-managed fisheries and VIC, TAS, South Australian, and some NSW State-managed fisheries and these are discussed in the following sections.

The interests of several Commonwealth-managed fisheries are represented by peak industry bodies. Details on industry bodies (where available) are provided with a record of all consultation carried out by TGS provided in **Section 5** and full transcripts in **Appendix H** of this EP.



Source: DoAWR, 2023

Figure 47 Australian Fishing Zone and Location of Commonwealth Fisheries

4.7.3.1 Review of Catch and Effort Data

Not all of the commercial fisheries identified with management areas overlapped by the EMBA are active within the OA. Commercial fishing catch and effort data for the recent five-year period 2016 – 2020 was obtained from the Australian Bureau of Agricultural and Resource Economics and Sciences (**ABARES**), Victorian Fisheries Authority (**VFA**), Department of Natural Resources and Environment Tasmania (**DNRET**) and Department of Primary Industries and Regions, South Australia (**PIRSA**) and has been reviewed to further understand the fisheries that are active in waters overlapping and adjacent to the OA.

Commonwealth fisheries effort is provided for a grid system based on divisions of approximately 1 arc hour latitude (approximately 60 NM), therefore, the data is of a coarse resolution and accurate fishing locations are not always apparent. For blocks where five or more vessels have fished per year, it has been possible for ABARES to map areas of relatively low, medium and high intensity fishing effort. For reporting blocks where fewer than five vessels have fished per year, detailed data remains confidential and ABARES have not mapped areas of relative fishing intensity; only the blocks are presented.

VIC fishing effort data is provided for a grid system based on divisions of 10' latitude (approximately 10 NM).

TAS fishing effort data is provided for a grid system based on divisions of 30' latitude (approximately 30 NM). Fishing effort and catch data was confidential for blocks where less than five boats had fished in a year. For some fisheries, this meant that the amount of relative effort or catch that could be mapped for each year of the five-year period was limited, but the presence or absence of catch is captured. Data was provided only for ten blocks that overlap or are adjacent to the OA; data for the wider fisheries was not provided so it is not possible to comment on relative fishing effort in the context of whole fisheries.

South Australian fishing effort data is provided for a grid system based on divisions of approximately 1 arc hour (approximately 60 NM). Fishing effort and catch data was confidential for blocks where less than five licences had fished in a year. For some fisheries, this meant that the amount of relative effort or catch that could be mapped for each year of the five-year period as a whole was limited, but the presence or absence of catch is captured. Data was provided for the South East Marine Fishing Area and Southern Zone of the Rock Lobster Fishery.

In addition to reviewing fishing effort data, TGS commissioned the South East Trawl Fishing Industry Association (**SETFIA**) to compile an additional review of the level of catch made by Commonwealth and State-managed fisheries within the OA, the proportion of each fisheries' total allowable catch and the annual average catch value that it represents (based upon data from the ten years prior to 2021).

The results the TGS and SETFIA catch data reviews are presented throughout the corresponding sections for each fishery. Note that the values presented represent the catch overlapped by the entire OA; given that the Otway Basin 3D MC MSS will be acquired in phases comprising more discrete areas, the area of effort, catch and its corresponding value overlapped during survey activities is likely to be significantly less. The information presented within this EP also encompasses the original OA, prior to the reduction of the OA from South Australian waters.

4.7.3.2 Commonwealth Managed Fisheries

The AFMA manages Australian fisheries on behalf of the Commonwealth Government from 3 NM to the edge of the Australian Fishing Zone. AFMA was established under the *Fisheries Administration Act 1991*, and it is under this Act, as well as the *Fisheries Management Act 1991*, that AFMA is invested with its objectives, functions, and powers.

AFMA looks after Commonwealth fisheries through:

- Research and science which provides the information to manage fisheries, such as the setting of quota levels;
- Management and regulation that develops and makes the rules for fisheries (e.g. quota and gear restrictions, and issuing of permits); and
- Monitoring and enforcement of rules and regulations.
- The aim of AFMA is to keep fish species, and the marine environment, in good health for the future. To achieve this, they work together with Australian State agencies, international counterparts, industry, scientists, and recreational and environmental fishery stakeholders (AFMA, 2023b).

AFMA ensures that impacts on commercial fisheries from petroleum activities, including MSSs, are considered by providing comment directly to the Department of Industry, Innovation and Science on annual acreage releases, and by providing comment to petroleum companies on proposals that may have significant impacts on fisheries. AFMA expects petroleum operators to consult directly with fishing operators about proposed petroleum activities. AFMA can provide data on fisheries but does not represent fishers. Note that in some fisheries there are no associations (AFMA, 2023c).

Consultation with commercial fishers that may be affected by the Otway Basin 3D MC MSS has been guided by AFMA recommendations and expectations. See **Section 5** and **Appendix H** for details on consultation with the commercial fishing sector.

Commonwealth-managed fisheries with management boundaries that overlap with the OA and EMBA include:

- Southern and Eastern Scalefish and Shark Fishery (**SESSF**);
- Small Pelagic Fishery (**SPF**);
- Southern Squid Jig Fishery (**SSJF**);
- Eastern Tuna and Billfish Fishery (**ETBF**);
- Southern Bluefin Tuna Fishery (**SBTF**);
- Bass Strait Central Zone Scallop Fishery (**BSCZSF**).

These fisheries are further described in **Section 4.7.3.2.1** to **Section 4.7.3.2.6**. Commonwealth fisheries that do not overlap with the OA or EMBA have not been included within this EP.

4.7.3.2.1 Southern and Eastern Scalefish and Shark Fishery

The SESSF is a multi-sector, multi-gear and multi-species fishery that targets a variety of stocks. The management area for the SESSF covers almost half of the Australian Fishing Zone and spans Commonwealth waters and Australian state waters.

The following sectors are of relevance to the OA and EMBA:

- Commonwealth Trawl Sector (**CTS**);
- Scalefish Hook Sector (**SHS**); and
- Gillnet, Hook and Trap Sector (**GHTS**).

Commonwealth Trawl Sector

The CTS extends south from Barrenjoey Point in northern NSW to east of Kangaroo Island, South Australia, and targets a variety of fish and shark species. The main species landed in the 2020/21 fishing season included blue grenadier, flathead, orange roughy (eastern zone), pink ling, and eastern school whiting. Vessels predominantly use demersal otter trawl and Danish-seine fishing methods, although pair trawling and mid-water trawling methods are also permitted under the SESSF management plan, albeit rarely used (Patterson *et al*., 2021). The fishing season for the CTS occurs year-round from 1 May to 30 April.

During the 2020/21 fishing season, 34 otter-board trawlers were active in the CTS, with 51,165 hours of fishing effort reported. In the same fishing season, 20 Danish-seine vessels were active, reporting a fishing effort of 10,715 shots. A total catch of 18,985t was reported for the 2020/21 fishing season.

The main trawl effort undertaken near the OA is for the otter-board trawl sector of the CTS. Fishing effort data indicates that fishing effort is primarily concentrated on the outer continental shelf and upper slope in waters shallower than 700 m, or shallower than 1,000 m, depending on closure areas in the fishery. The OA overlaps with areas of low to high fishing intensity along the northern and southwestern boundary, with fishing also occurring across the OA albeit at low intensity (five or fewer vessels) (**Figure 48**). The OA overlaps approximately 4.6% of the total catch overlap with the CTS, equating to an average annual revenue overlap of $3,689,568. The EMBA also overlaps with areas of low to high fishing intensity parallel to the South Australia and VIC coast, surrounding TAS, and north from TAS along the VIC and NSW regions (**Figure 48**).

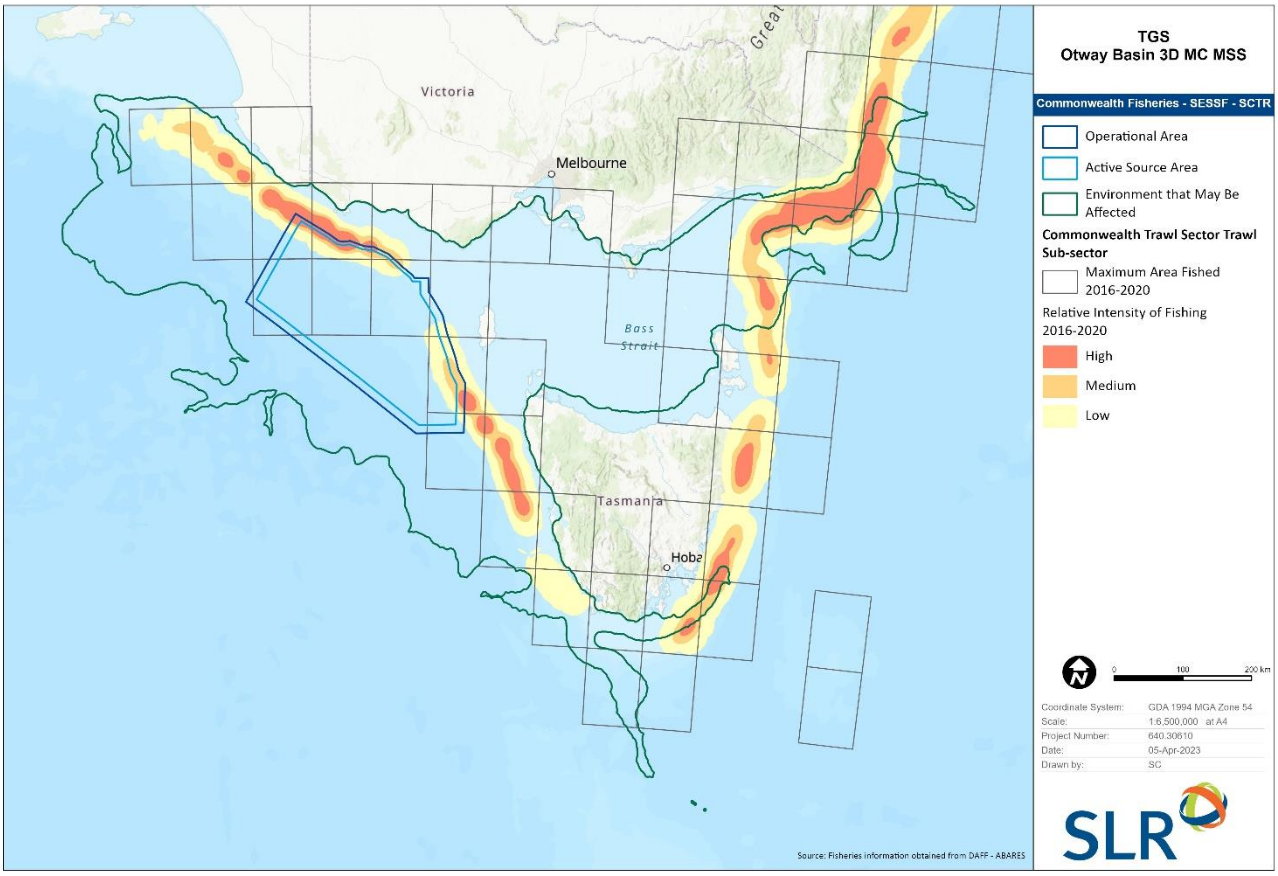


Figure 48 Relative Fishing Intensity in the Commonwealth Trawl Sector (2016 – 2020)

Scalefish Hook Sector

The SHS extends around south-eastern Australia to the border between South Australian and Western Australia. This fishery targets a variety of fish and shark species, with the main species landed in 2020/21 being pink ling, blue-eye trevalla, and ribaldo. Fish within this sector are caught using longline and dropline methods, some of which are automated (Patterson *et al*., 2021). The fishing season for the SHS occurs year-round from 1 May to 30 April.

For the 2020/21 fishing season, there were 20 active scalefish hook vessels, with a total fishing effort of 4.4 million hooks returning a total catch of 665t (Patterson *et al*., 2021).

Fishing effort data indicates that fishing effort is generally reported as <5 vessels per 60 NM reporting block, with only a few areas of fishing intensity mapped off southern and eastern TAS overlapping the EMBA (**Figure** 49). The OA overlaps approximately 7.3% of the total catch overlap with the SHS, equating to an average annual revenue overlap of $378,432.

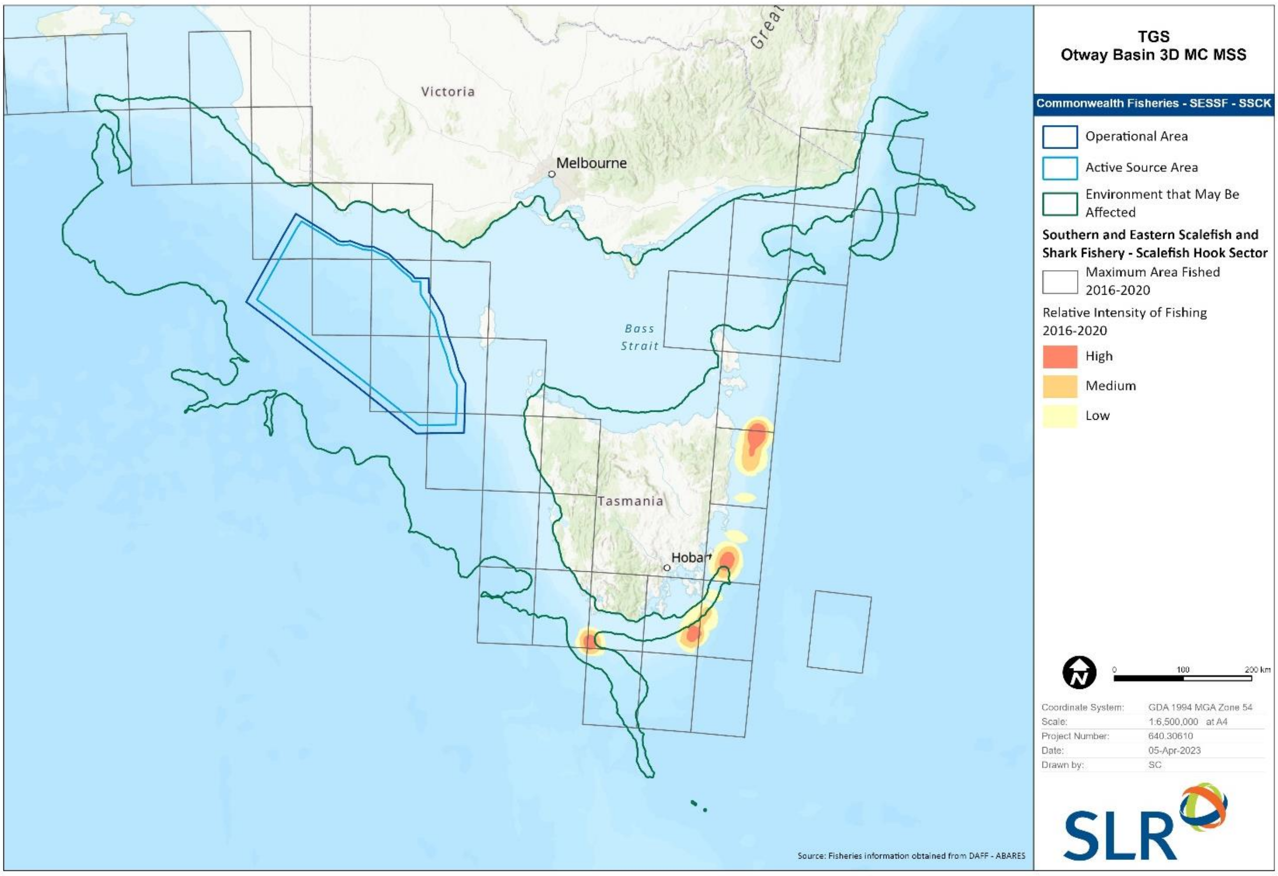

Figure 49 Relative Fishing Intensity in the Southern and Eastern Scalefish and Shark Fishery – Scalefish Hook Sector (2016 – 2020)

Gillnet, Hook and Trap Sector

The Shark Gillnet and Shark Hook Sectors (**SGSHS**) are part of the GHTS of the SESSF. Most net fishing in the SGSHS occurs in Bass Strait, while most hook fishing occurs off South Australia (Patterson *et al.*, 2021). Spatial closures (implemented since 2003) have resulted in gillnet effort being concentrated off VIC, with an increase in hook effort to replace gillnet effort off South Australia. The SGSHS utilises demersal gillnet and demersal longline fishing methods to target gummy sharks and sawsharks, with elephantfish caught as bycatch. The fishing season for the SGSHS extends from 1 May to 30 April.

During the 2020/21 fishing season, there were 13 hook permits and 38 active hook vessels, recording a hook effort of 2.88 million hooks. In the same season, there were 61 gillnet permits and 31 active gillnet vessels, hauling a gillnet effort of 27,782 km (Patterson *et al.*, 2021).

Fishing effort from the SGSHS within the OA is limited to relatively few vessels (<5 vessels per 60 NM block per year) (**Figure 50** and **Figure 51**). The OA overlaps approximately 0.2% of the total catch overlap with the SGSHS, equating to an average annual revenue of $38,670.

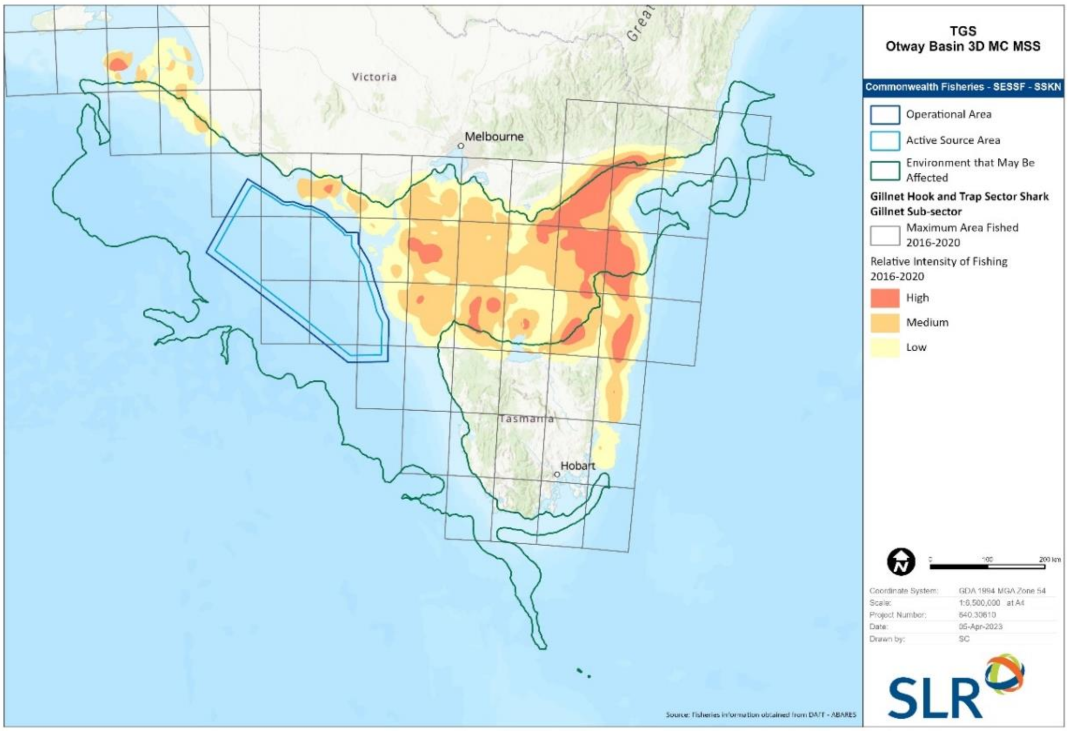

Figure 50 Relative Fishing Intensity in the Gillnet Hook and Trap (Shark Gillnet Sub-sector) Fishery (2016 – 2020)

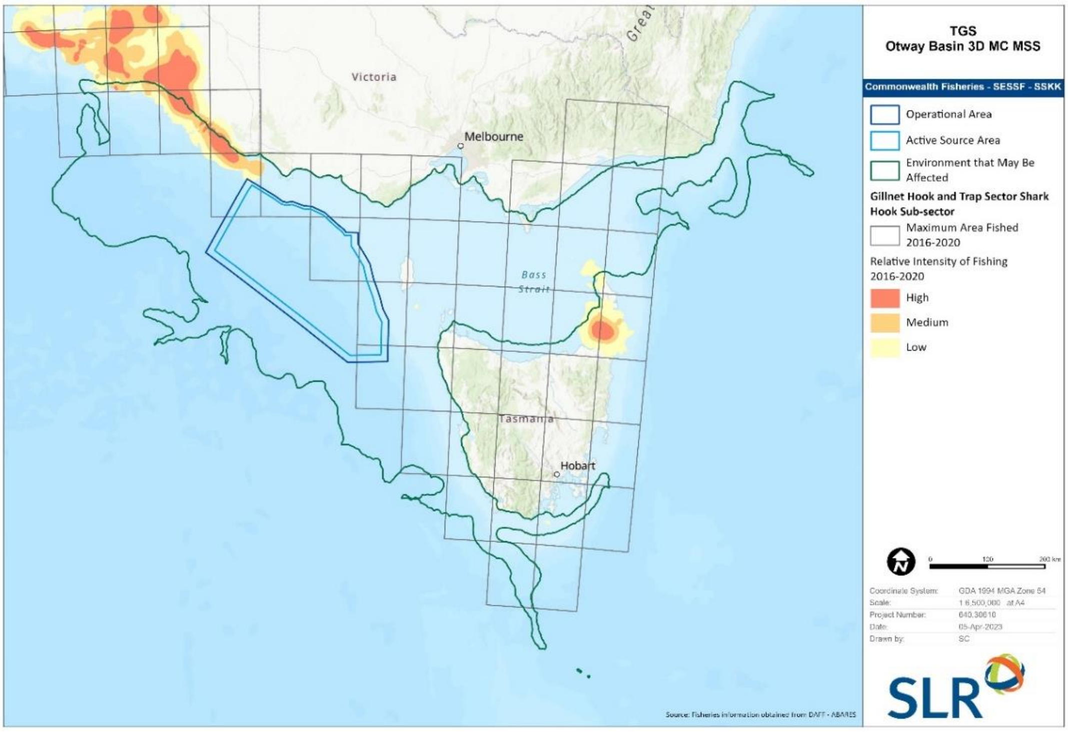

Figure 51 Relative Fishing Intensity in the Gillnet Hook and Trap (Shark Hook Sub-sector) Fishery (2016 – 2020)

4.7.3.2.2 Small Pelagic Fishery

The SPF extends from southern QLD to southern Western Australia. It has three subareas (east, west and sardine), with separate TACs for each of the seven stocks. The SPF includes purse-seine and midwater trawl fishing vessels targeting blue mackerel, jack mackerel, and redbait (in the east and west subareas), and Australian sardine in the sardine subarea (Patterson *et al*., 2021). The fishing season for the SPF is from 1 May to 30 April.

Historically, most fishing effort has occurred off the east coast of TAS and NSW. 31 entities held fishing permits during the 2019/20 and 2020/21 fishing seasons. Total catch was 16,093t over 200 hours, and 13,766t over 141 hours for the 2019/20 and 2020/21 seasons respectively (Patterson *et al*., 2021), representing a decrease in fishing effort between seasons.

Fishing effort is relatively low and limited to blocks with fewer than five vessels per 60 NM block per year. Recent fishing effort has mainly occurred off the coast of NSW and eastern TAS, although some effort between 2016 and 2020 has also occurred in waters off South Australia.

There has been no fishing associated with the SPF within the OA, however, the wider EMBA does overlap with fishing blocks where fewer than five vessels have fished in a year (**Figure 52**).

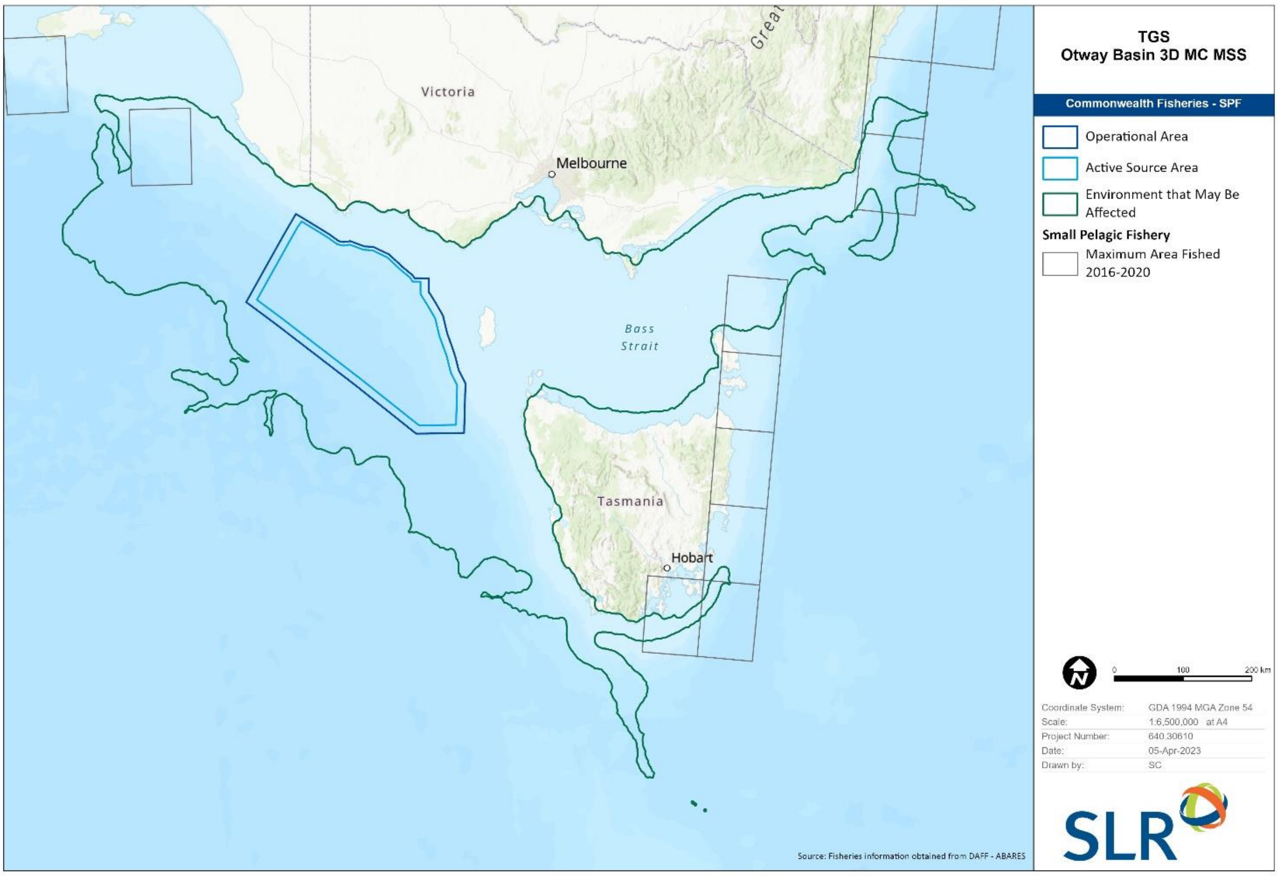

Figure 52 Relative Fishing Intensity in the Small Pelagic Fishery (2016 – 2020)

4.7.3.2.3 Southern Squid Jig Fishery

The SSJF is located off NSW, VIC, TAS and South Australia, and in a small area of oceanic waters off southern QLD. Jig vessels operate at night in depths of 60 – 120 m targeting Gould's squid (Patterson *et al*., 2021). The fishing season for the SSJF runs from 1 January to 31 December.

Historically, fishing intensity has been highest off the coast of Portland, VIC. In 2020, there were 4,800 gear statutory fishing rights, five active vessels, and a total of 1,711 jig-hours. The 2020 total catch was 480t (Patterson *et al*., 2021).

Catch for the 2016 – 2020 fishing seasons was reported off Portland, VIC, and the east coast of TAS. No areas of high fishing intensity overlap with the OA, however, low - high intensity fishing effort has occurred along the northern boundary of the OA and some fishing events (no intensity reported due to confidentiality) have occurred throughout the OA (**Figure 53**). The OA overlaps with approximately 4.9% of the total catch for 2016 – 2020, representing an average annual revenue overlap of $14,920.

It is noted that effort in the SSJF is highly variable due to the fluctuating market value of squid. Prior to 2016, effort occurred off the west coast of TAS in waters adjacent to the SE of the OA.

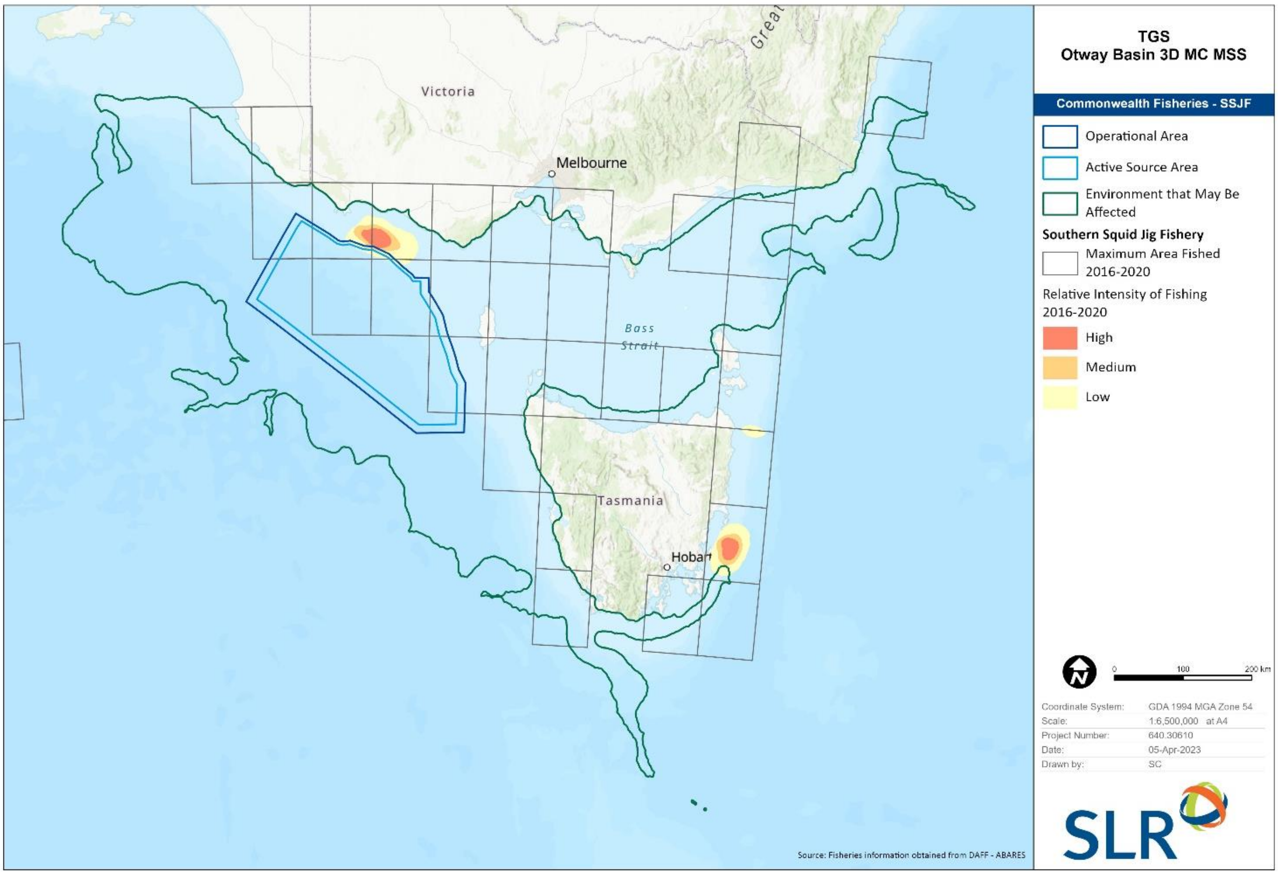

Figure 53 Relative Fishing Intensity in the Southern Squid Jig Fishery (2016 – 2020)

4.7.3.2.4 Eastern Tuna and Billfish Fishery

The Eastern Tuna and Billfish Fishery (**BTBF**) represents one of three tuna fisheries in Australia. This fishery extends from the tip of Cape York, QLD, eastwards around the Eastern Australian coast, terminating at the South Australian/VIC border. The management of the ETBF is influenced by the Western Central Pacific Fisheries Commission (**WCPFC**) to which Australia is a signatory. The WCPFC applies a regional quota, which is subject to an Australian domestic harvest strategy, management arrangements, and setting of annual total allowable catch (Tuna Australia, 2023).

The ETBF is currently accessed through Australian licensed fishing effort. There was also foreign effort through joint venture arrangements with various countries up until 1995. At its peak, there were 230 active vessels in the industry. Currently, there are up to 35 boats actively longlining within areas of the ETBF on any given day during the fishing season, with fishing location changing based on seasonal fish abundance and known events (Tuna Australia, 2023).

Catch rates of yellowfin tuna are indicating a ‘pulse event’ is occurring (high abundance of tuna), driven by eddy formation dynamics, climate influences, prey availability, and other unknown factors (Tuna, Australia, 2023). A sustained pulse event may change the dynamics of individual fishing strategies, for example, some boats may fish while other boats may move to target areas around TAS in April (Tuna Australia, 2023).

There are five quota species in this fishery: bigeye tuna, yellowfin tuna, albacore, swordfish, and striped marlin. Boats operating within the ETBF target southern bluefin tuna from May – October, with some continuing through to December if market conditions allow. This catch is dependent on available quote after the purse seine sector has finished their catching season (Tuna Australia, 2023).

The northern part of the OA overlaps with blocks where five or fewer vessels per year are reported to have fished. The EMBA overlaps with fishing blocks of low to high fishing effort in the northeast along the VIC/NSW border (**Figure 54**).

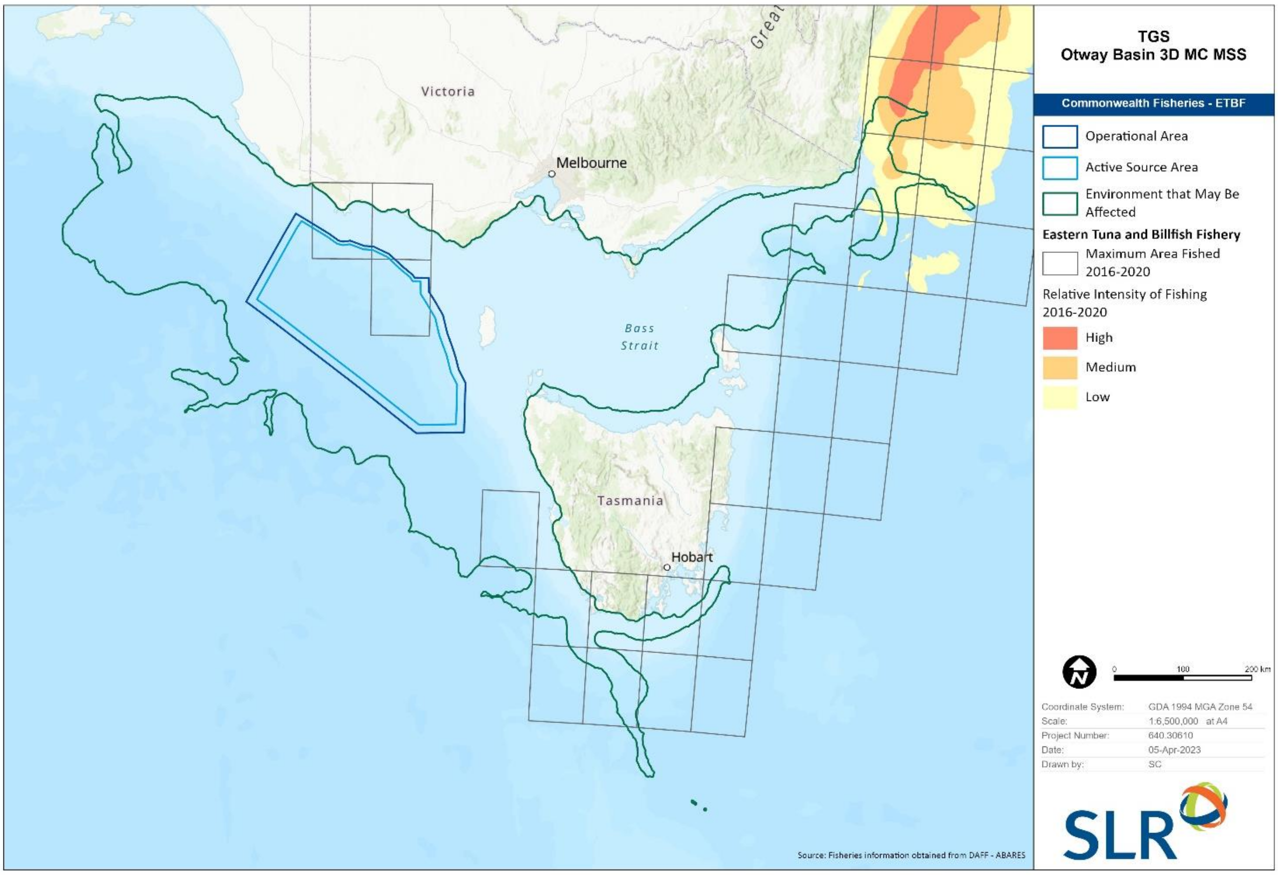

Figure 54 Relative Fishing Intensity in the Eastern Tuna and Billfish Fishery (2016 – 2020)

4.7.3.2.5 Southern Bluefin Tuna Fishery

The SBTF spans the Australian Fishing Zone. Southern bluefin tuna (*Thunnus maccoyii*) is targeted by fishing fleets within the Australia's EEZ. Young fish (1 – 4 years of age) move from the spawning ground in the north-east Indian Ocean into the Australian EEZ and southwards along the Western Australian coast (Patterson *et al*., 2021). The fishing season for the SBTF extends from 1 December to 30 November.

Since 1992, most of the Australian catch has been taken by purse seine, targeting juvenile southern bluefin tuna (2 – 5 years of age) in the GAB, west of the OA. This catch is transferred to aquaculture farming operations off the coast of Port Lincoln in South Australia, where the fish are grown to a larger size to achieve higher market prices. Australian domestic longliners operating along the east coast also catch southern bluefin tuna, and there is some recreational fishing for the species (Patterson *et al*., 2021).

The Australian market is often void of premium quality wild tuna from December to April. As southern bluefin tuna migratory patterns have moved significantly to the east, there is interest in targeting fish across the OA and into Bass Strait from December to April, with fishers then following the tuna to winter grounds (Tuna Australia, 2023).

The number of active purse seine vessels within the SBTF has been stable since 1994, ranging from five to eight vessels. Abundant availability of inshore southern bluefin tuna off the TAS and VIC coastline is driving an increased interest in the minor-line method, reflected in an increase in minor-line Statutory Fishing Right transactions (Tuna Australia, 2023).

During the 2019/20 fishing season, there were seven purse seine and 23 longline vessels active in the SBTF. Total catch for this season was 5,429t over 1,248 search hours and 146 'shots' (Patterson *et al.*, 2021).

Fishing within the SBTF is typically on the outer continental shelf or deeper waters in the GAB or south of Kangaroo Island. High purse seine fishing effort has been reported northwest of the OA within the GAB; these areas overlap with the EMBA, with no overlap reported for the OA (**Figure 55**). Long-lining associated with the SBTF is reported along the NSW coastline. This area of low to high intensity overlaps with the northeast of the EMBA. Fishing blocks of five vessels or less have also been reported throughout the EMBA and overlapping with the OA (**Figure 56**) although due to the low number of vessels utilising these blocks, an estimate of total catch overlap and average annual revenue overlap is not able to be presented.

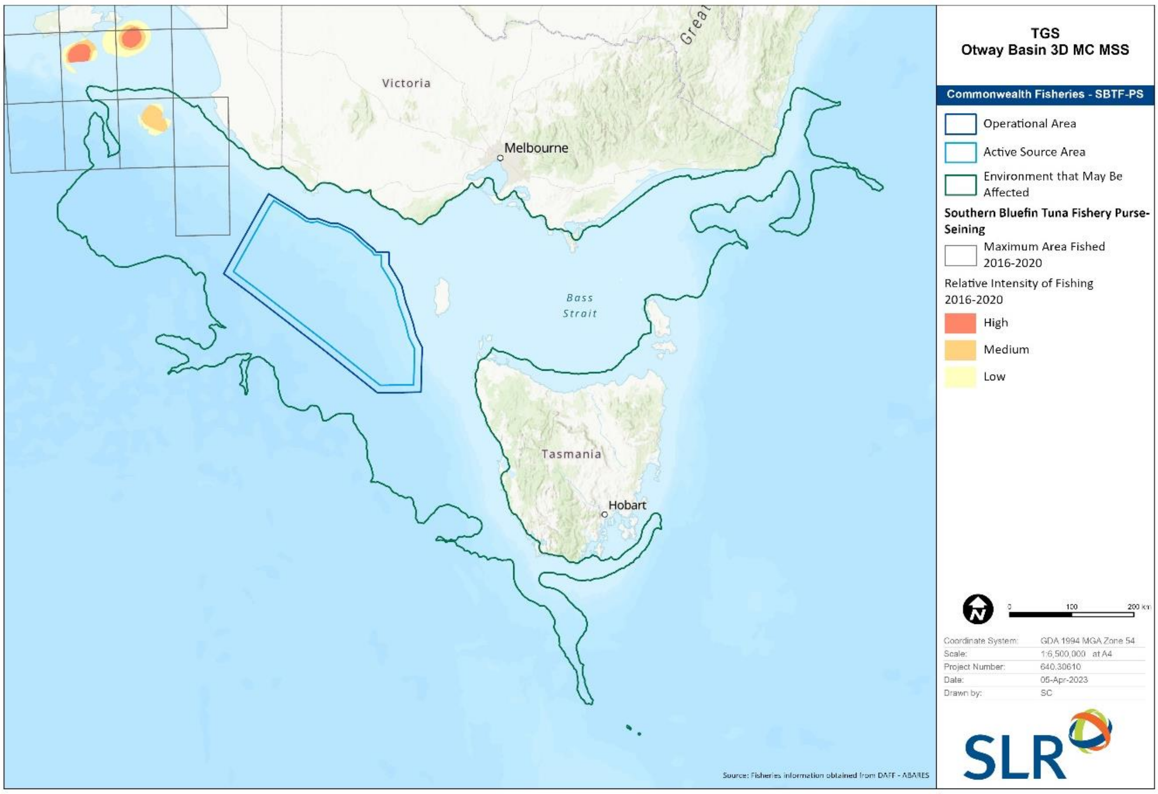

Figure 55 Relative Fishing Intensity in the Southern Bluefin Tuna (Purse-Seining) Fishery

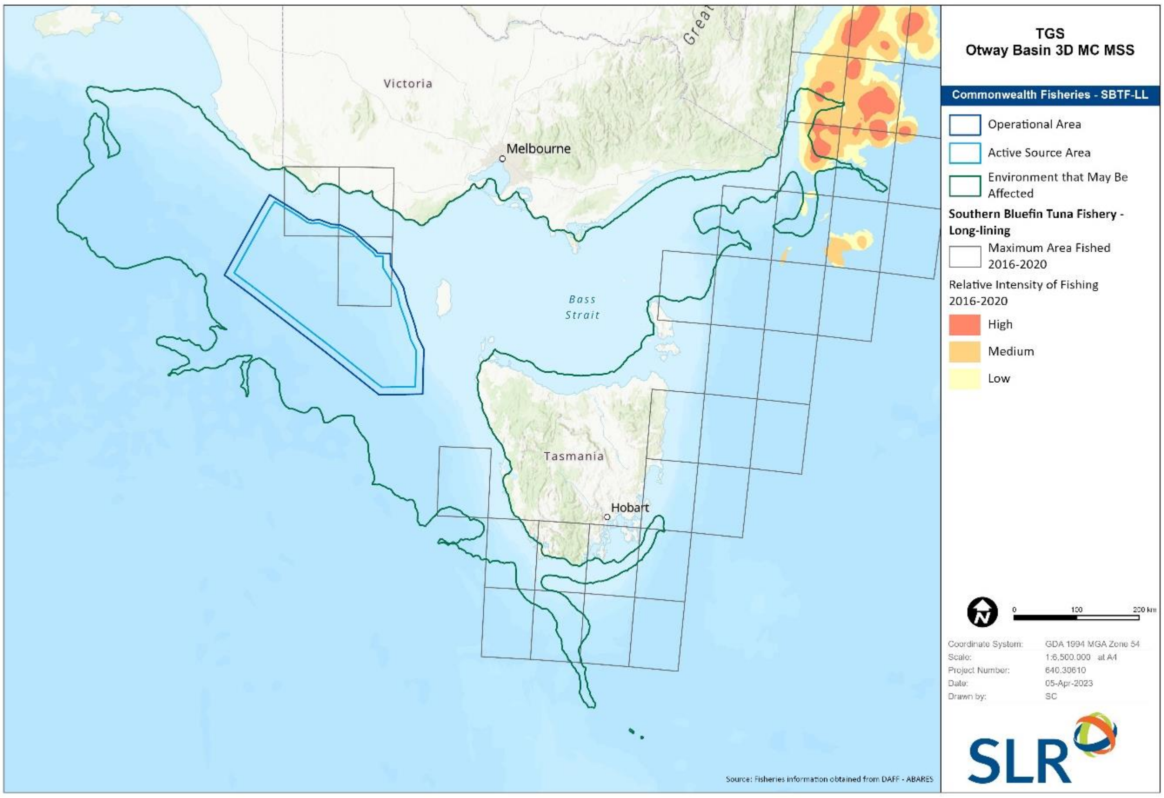

Figure 56 Relative Fishing Intensity in the Southern Bluefin Tuna (Long-Lining) Fishery

4.7.3.2.6 Bass Strait Central Zone Scallop Fishery

The BSCZSF operates in the central area of Bass Strait, between the VIC and TAS scallop fisheries. It is a single species fishery that targets dense aggregations ('beds') of commercial scallop using scallop dredges. In 2021, fishing was permitted throughout the fishery, except over four scallop beds that were closed under the BSCZSF harvest strategy. In 2021, fishing was concentrated over eastern and western Bass Strait beds (Patterson *et al.,* 2021). Fishing effort occurs between July and December.

In 2009, the BSCZSF re-opened following a three-year closure. 26 active vessels fished in this fishery, with this number decreasing to 12 by 2019 and nine in the 2020 fishing season. Total catch in the 2020 fishing season was 2,732t over 4,727 hours of fishing effort (Patterson *et al*., 2021).

The OA overlaps part of a single 60 NM fisheries reporting block to the west of King Island (**Figure 57**) with this block representing where five or fewer vessels per year are reported to have fished. Due the low numbers of vessels reported for this fishing block, an estimate of the percentage of total catch overlap and average annual revenue overlap with the OA cannot be calculated. The wider EMBA overlaps with areas of low to high relative intensity of fishing to the northeast of King Island, and northeast of Flinders Island (**Figure 57**).

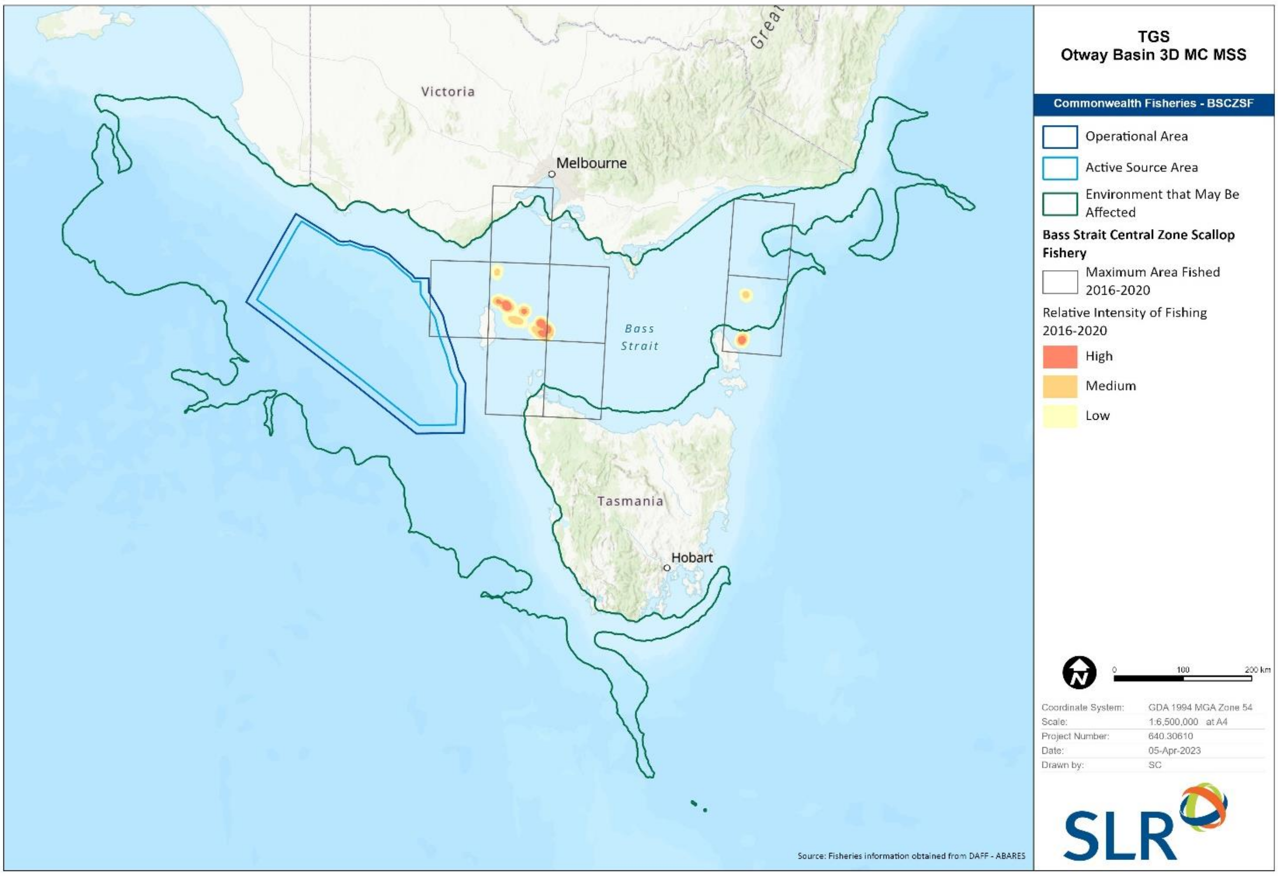

Figure 57 Relative Fishing Intensity in the Bass Strait Central Zone Scallop Fishery (2016 – 2020)

4.7.3.3 Victorian Managed Fisheries

The Victorian Fisheries Authority (**VFA**) is an independent statutory authority that was established to manage VIC fisheries resources. By working with stakeholders, the VFA aims to deliver on three main outcomes: sustainable fishing and aquaculture, clear resource access and sharing arrangements, and increased economic, social and cultural value. The VFA manages commercial fisheries through licencing and quota management, enforcement of the provisions of the Fisheries Act 1995, support of sustainable and responsible fishing and aquaculture, and research and fishery monitoring and assessments (VFA, 2023a).

VIC State-managed fisheries that overlap with the OA and EMBA are discussed in **Section 4.7.3.3.1** – **Section 4.7.3.3.11**.

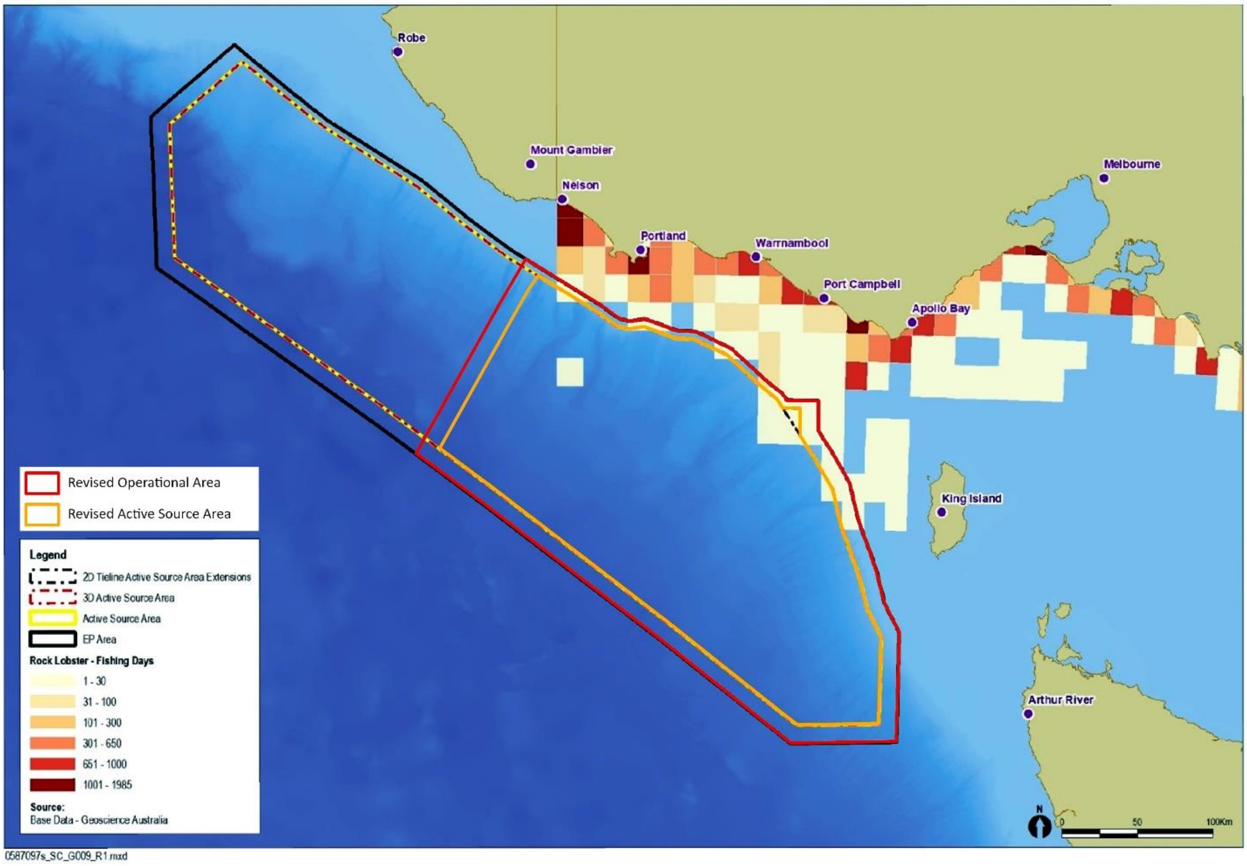
4.7.3.3.1 Rock Lobster Fishery

The rock lobster fishery is VICs most valuable fishery and is based on the southern rock lobster (VFA, 2023b). The fishery extends along the VIC coast, out to Commonwealth waters. It is managed in two separate zones; the Western Zone and Eastern Zone, with separate Total Allowable Commercial Catch set for each zone. The majority of catch in the VIC rock lobster fishery originates from the Western Zone, within which the OA overlaps.

Spawning of rock lobster in Victoria waters occurs from June – November. The rock lobster fishery is closed from 1 June to 15 November for females (to protect berried females during the spawning season) and 15 September to 15 November for males (to protect males during the moulting period). Catch has historically increased from a minimum in September to a peak in December and January, followed by a gradual decrease. Most catch caught from the Western Zone is landed through Portland, Port Fairy, Warrnambool, Port Campbell, and Apollo Bay. Almost all VICs commercial rock lobster catch is usually exported to international markets, predominantly Asia; however, since 2020 there has been a shift of the primary market back to domestic sales (VFA, 2023b).

The rock lobster fishery primarily operates on the continental shelf and is greatest in water depths less than 100 m. It is understood from consultation with rock lobster stakeholders that fishing in the deep waters happens occasionally when targeting 'white fish' to bulk up and order for a large amount of lobster meat where the red lobster appearance (associated with shallow waters) is not needed.

All areas of high fishing intensity (i.e. >100 fishing days) are outside of the OA. A relatively low level (1 – 30 fishing days) of fishing intensity has occurred along the northern boundary of the OA and towards King Island, with one fishing block along the northern boundary experiencing slightly higher fishing intensity (31 – 100 fishing days) (**Figure 58**). A single block also appears to have been fished within the centre of the OA (**Figure 58**); however, given the deep waters (>2,000 m) associated with this block, it is possible that this a logbook entry error. Overall, the OA overlaps with approximately 2% of the total catch, equating to $265,430 average annual revenue overlap.



Note: The OA and AA have been revised since this image was produced, with the revised areas overlaid on top.

Figure 58 Fishing Intensity (Fishing Days) in the Victorian Rock Lobster Fishery (2016 – 2020)

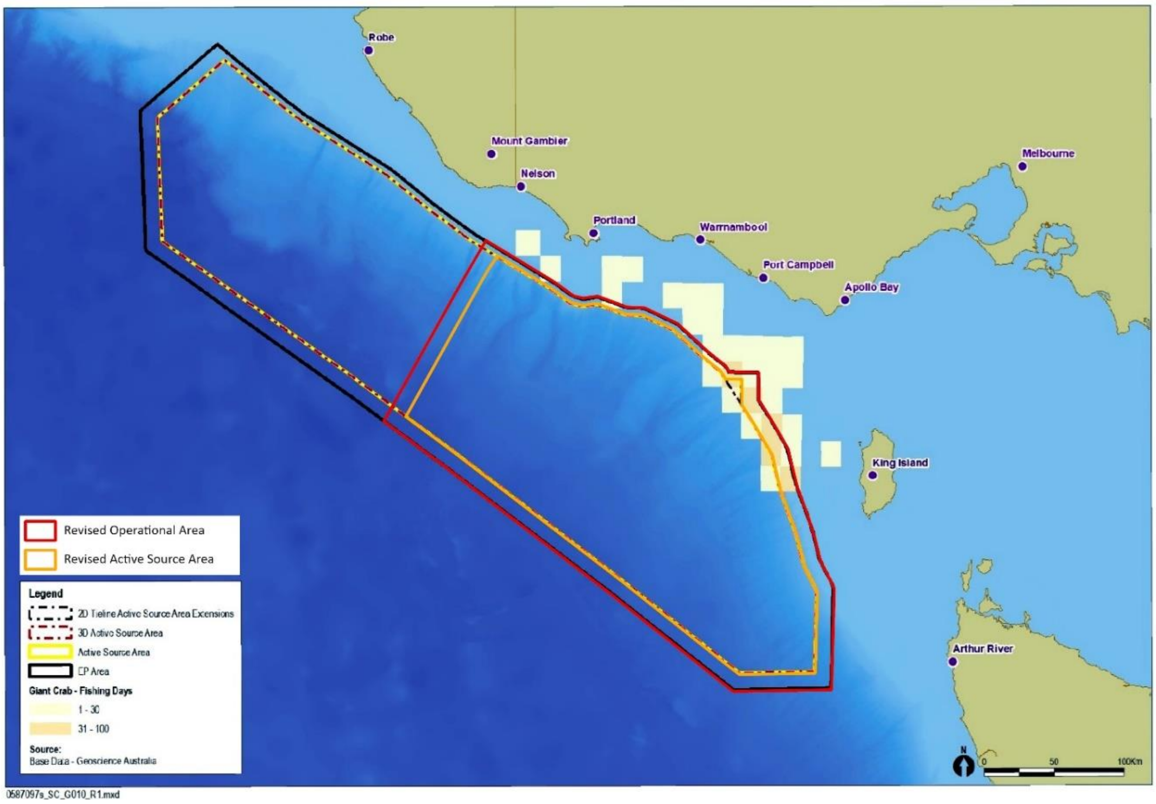
4.7.3.3.2 Giant Crab Fishery

The giant crab fishery is a small, limited entry fishery (maximum 30 licences) that is closely linked to the VIC rock lobster fishery; a Giant Crab Fishery (Western Zone) Access Licence can only be operated when it is joined to a Rock Lobster Fishery (Western Zone) Access Licence. The boundaries of this fishery mimic those of the VIC rock lobster fishery in the Western Zone. Fishers target giant crabs (*Pseudocarcinus gigas*) using baited rock lobster pots (VFA, 2023c).

The fishery is closed for taking female giant crabs from 1 June to 15 November, and from 15 September to 15 November for males. This provides protection to female crabs during the spawning season and prevents the use of pots during the closed season for rock lobster. There is a total year-round ban on the retention of berried females (VFA, 2023c).

Targeted fishing for giant crabs began in the 1990s, with a general decline in catch and associated effort in the fishery since. Since the introduction of quota in 2001, there have been five or less dedicated fishers active in the giant crab fishery, and up to 20 fishers annually reporting giant crab catch as bycatch from the rock lobster fishery. The total landed catch of giant crab in the 2019/20 (1 July 2019 to 30 June 2020) quota season was 9.8t (VFA, 2023c).

Fishing effort typically targets the edge of the continental shelf between western VIC and TAS (VFA, 2023c). However, the greatest fishing effort occurs in five blocks overlapping water depths less than 1,000 m along the north-eastern edge of the OA, overlapped by the 2D tie line (**Figure 59**). Effort in these blocks ranges from 41 to 92 days over the five-year data period (2016 – 2020). The OA overlaps approximately 62% of the total catch overlap with the giant crab fishery, representing $138,159 average annual revenue overlap.



Note: The OA and AA have been revised since this image was produced, with the revised areas overlaid on top.

Figure 59 Fishing Intensity (Fishing Days) in the Victorian Giant Crab Fishery (2016 – 2020)

4.7.3.3.3 Octopus Fishery

The VIC octopus fishery is a relatively new fishery (commenced on 1 August 2020) targeting pale octopus (*Octopus pallidus*) in East Gippsland. Maori octopus (*Macroctopus maorum*) and gloomy octopus (*O. tetricus*) may also be taken. The fishery utilises purpose-built un-baited traps which minimises by-catch.

The fishery is a limited entry fishery with only 11 licences issued. Gear restrictions also exist limiting the number of lines of octopus pots and the number of pots attached to each line. Currently licences only allow the harvesting of octopus from the Eastern Octopus Zone, which extends from approximately Seaspray to the VIC/NSW border and out to 20 NM offshore (VFA, 2023d).

The VIC octopus fishery does not overlap with the OA but may overlap with the EMBA. No estimation of total catch overlap and average annual revenue overlap has been provided.

4.7.3.3.4 Abalone Fishery

The abalone is one of VICs most valuable commercial fisheries, with most of the catch exported to international markets. The fishery primarily targets blacklip abalone (*Haliotis rubra*), with greenlip abalone (*H. laevegata*) also targeted in lower numbers (VFA, 2023e).

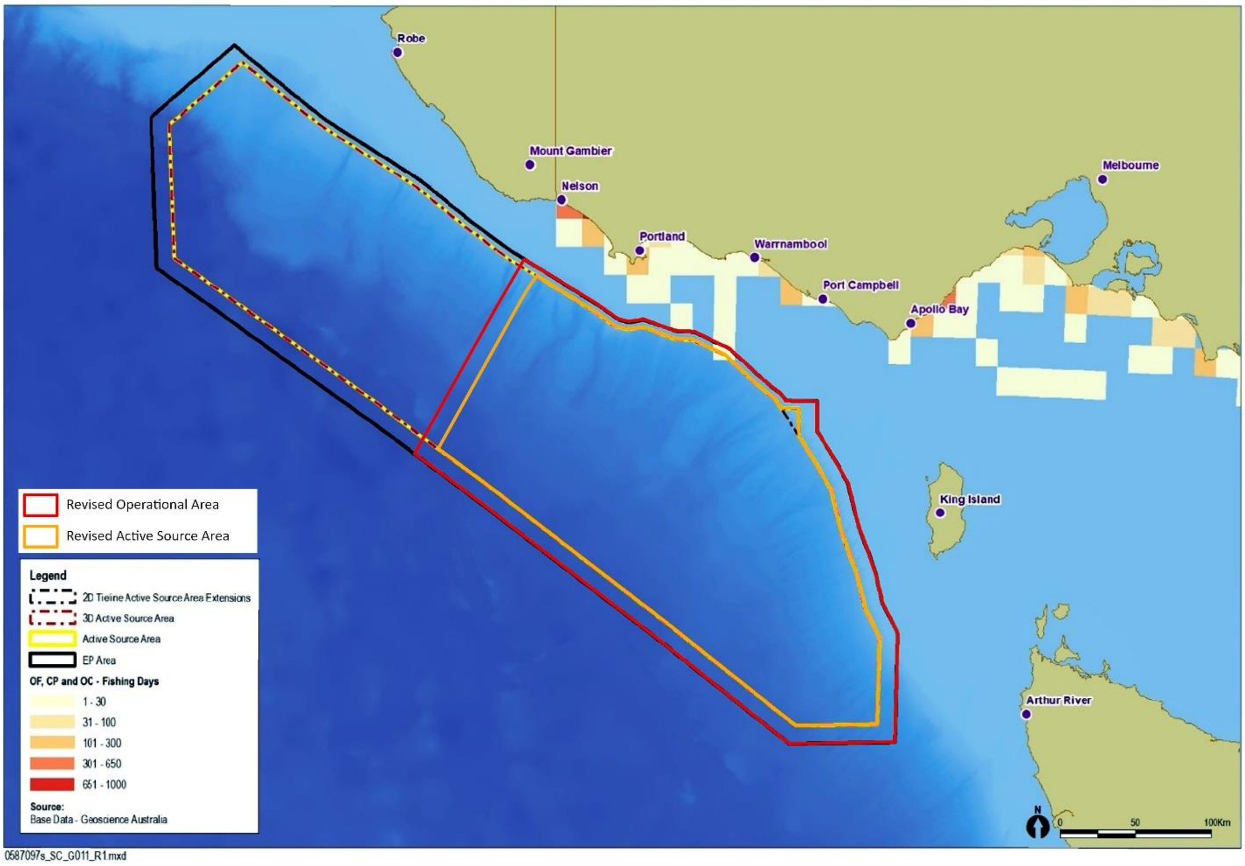
VIC's commercial abalone fishery is subdivided into three management zones: Western Zone, Central Zone, and Eastern Zone. The OA is adjacent to the Western Zone and the western end of the Central Zone. There is a total of 71 Abalone Access Licences within the Victorian fishery: 14 in the Western Zone, 34 in the Central Zone and 23 in the Eastern Zone. This equates to a maximum of 71 divers operating on any particular day across the fishery (VFA, 2023e).

As this fishery is a dive fishery, there will be no overlap with the OA, although the fishery may overlap with the EMBA. No estimation of total catch overlap and average annual revenue overlap has been provided.

4.7.3.3.5 Wrasse (Ocean Fishery)

The VIC wrasse (ocean) fishery extends along the entire length of the VIC coastline and out to 20 NM. It was established in the 1990s when a domestic market based on live trade to restaurants and seafood outlets was created. Although the fishery is divided into three commercial management zones (West, Central and East), licence holders can fish in any of these zones. Most fish are harvested by hook and line methods. Target species include bluethroat wrasse and purple wrasse (90% of the commercial harvest), rosy wrasse, senator wrasse, and southern maori wrasse (VFA, 2023f).

As shown in **Figure 60**, the OA overlaps with a single fishing block. This relates to a single day reported in 2020 by one fisher in the Ocean Fishery.



Note: The OA and AA have been revised since this image was produced, with the revised areas overlaid on top.

Figure 60 Fishing Intensity (Fishing Days) in the Victorian Ocean Fish, Commercial Permit, and Octopus Fishery Fisheries (2016 – 2020)

4.7.3.3.6 Scallop (Ocean) Fishery

The VIC scallop fishery extends out to the 20 NM limit from the high tide water mark, but excludes the bays and inlets along the coast where commercial scalloping is prohibited. The scallop species *Pecten fumatus* is mostly targeted, although incidental catches or doughboy scallops (*Chlamys asperrimus*) are taken as by-product (VFA, 2023g).

Historically, the majority of the fishing activity in the VIC zone has occurred in the eastern waters of VIC, with most vessels launching from the ports of Lakes Entrance and Welshpool. Following anecdotal reports of high abundances of commercial-sized scallops off the Tarwine oil and gas field, scallop abundance surveys were conducted which identified several scallop beds, seeing the return of a viable scallop fishery in VIC and positive signs of recruitment elsewhere in the fishery (VFA, 2023g).

The number of licences available within the VIC scallop fishery has been capped at 91, and approximately 10 – 15 boats operate in the fishery (VFA, 2023g).

4.7.3.3.7 Scallop Dive (Port Phillip Bay) Fishery

The Scallop Dive (Port Phillip Bay) Fishery was established in 2013 and targets the commercial scallop and doughboy scallop. The fishery is managed by a single commercial access licence, and harvesting is restricted to hand harvesting only (VFA, 2023h).

There is no overlap between the Scallop Dive (Port Phillip Bay) Fishery and the OA, although the fishery may overlap with the EMBA. No estimation of total catch overlap and average annual revenue overlap has been provided.

4.7.3.3.8 PQ Aquatics Fishery

PQ Aquatics Syngnathids Wildlife Trade Operation operates in the VIC coastal waters of Western Port Bay and primarily Port Phillip Bay. PQ Aquatics Syngnathids Wildlife Trade Operation harvests various species of syngnathids (seahorses, pipefish and seadragons), with the specific species able to be harvested controlled under permit conditions prescribed by the VFA. Specifically, weedy seadragon (*Phyllopteryx taeniolatus*), short-headed seahorse (*Hippocampus breviceps*) and pot-bellied seahorse (*H. abdominalis*) are collected by hand for sale in the aquarium trade (DAWE, 2021).

There is no overlap between the PQ Aquatics Fishery and the OA, although the fishery may overlap with the EMBA. No estimation of total catch overlap and average annual revenue overlap has been provided.

4.7.3.3.9 Sea Urchin Fishery

Following the introduction of regulatory arrangements on 1 August 2014, sea urchins can be harvested in eastern VIC and Port Phillip Bay under a Sea Urchin Fisheries Access Licence. The fishery utilises divers to harvest white sea urchin (*Heliocidaris erythrogramma*) and black long-spined sea urchin (*Centrostephanus rodgersii*) (VFA, 2023i).

As this fishery is diver-based, it does not overlap with the OA, although the fishery may overlap with the EMBA. No estimation of total catch overlap and average annual revenue overlap has been provided.

4.7.3.3.10 Pipi Fishery

The VIC Pipi Fishery has been managed under a quota management regime since regulations came into force in February 2020, with the new fishery commencing on 1 April 2020. Although the fishery covers the entire VIC coastline, Pipi Fishery Access Licences have only been issued for the Discovery Bay and Venus Bay commercial management zones (VFA, 2023j). The fishery targets the pipi (*Donax deltoides*) which inhabit the surf zone of high-energy sandy beaches. No other species can be retained. Pipi are collected using dip nets (VFA, 2018).

The Pipi Fishery does not overlap with the OA, although the fishery may overlap with the EMBA. No estimation of total catch overlap and average annual revenue overlap has been provided.

4.7.3.3.11 Corner Inlet Fishery

The Corner Inlet (Nooramunga) Fishery is one of VIC's most important fisheries. It is a significant supplied of local seafood and supports local employment in southern Gippsland. The fishery is located in South Gippsland and includes all marine waters inshore of the five main entrances from Bass Strait: Port Welshpool entrance, Port Albert entrance, Kate Kearney entrance, Shoal/Shallow Inlet entrance, and McLoughlin's Beach entrance (VFA, 2022).

The fishery is a multi-species fishery, with more than 20 species caught on a regular basis. The 12 most important species in the fishery are: King George whiting, southern sea garfish, southern calamari, rock flathead, gummy shark, southern bluespotted flathead, southern sand flathead, greenback flounder, silver trevally, Australian salmon, snapper, and yellow-eye mullet (VFA, 2022).

There are 18 transferrable Corner Inlet Fishery Access Licences which are mostly all currently active, however, some are operated on a part-time basis. Fish are predominantly taken via seine nets and mesh nets, although longline and other fishing gear (including hoop nets and hand lines) are also authorised under this licence class and are occasionally used (VFA, 2022).

The Corner Inlet Fishery does not overlap with the OA, although the fishery may overlap with the EMBA. No estimation of total catch overlap and average annual revenue overlap has been provided.

4.7.3.4 Tasmanian Managed Fisheries

Commercial fisheries within TAS waters are managed by the Tasmanian Government Department of Natural Resources and Environment Tasmania (**DNRET**). DNRET is responsible for the sustainable management of the State’s natural and cultural heritage and the integrity of the racing industry for the benefit of the TAS community (DNRET, 2023).

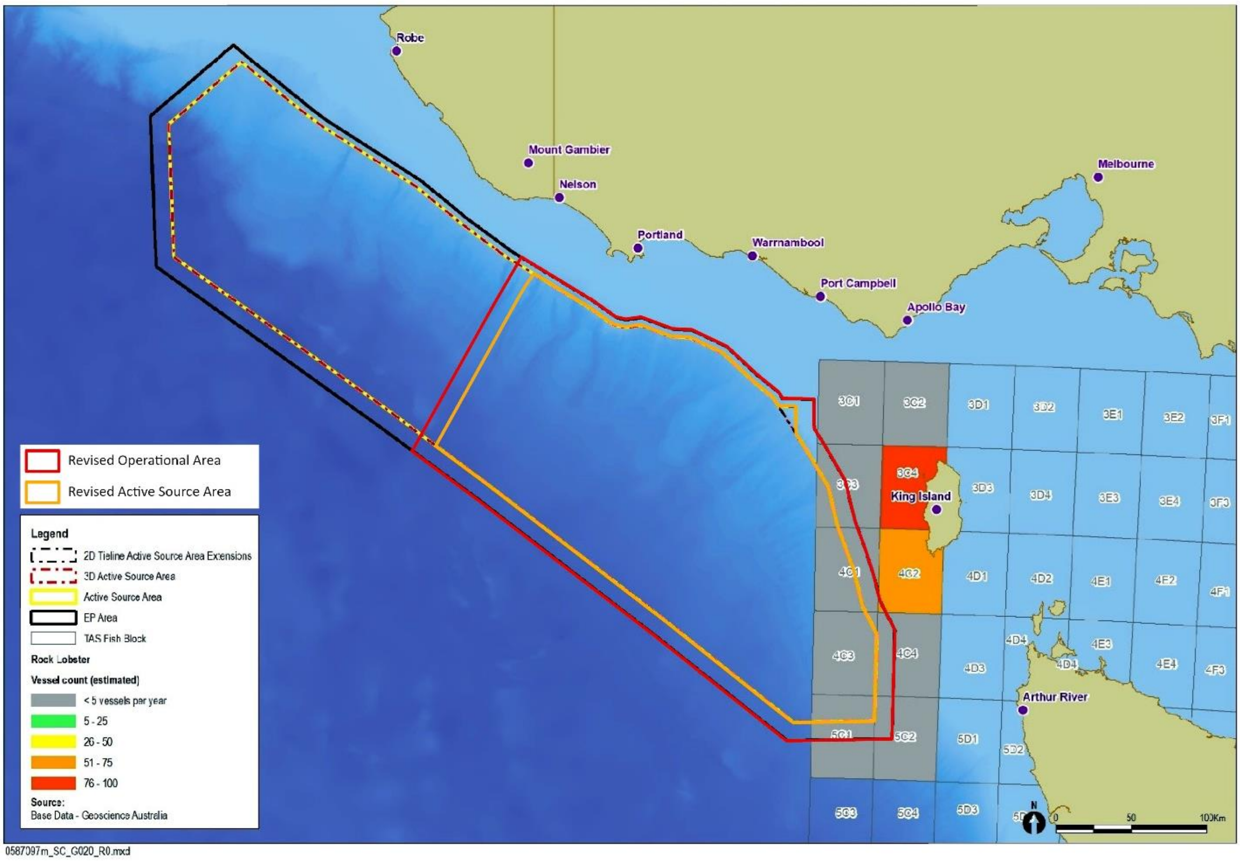
TAS State-managed fisheries that overlap with the OA and EMBA are discussed in **Section 4.7.3.4.1** – **Section 4.7.3.4.9**.

4.7.3.4.1 Rock Lobster Fishery

The rock lobster fishery is a major Tasmanian industry providing significant benefits from exports from the commercial fishery and is also highly valued by recreational and Aboriginal fishers. The fishery primarily targets southern rock lobster (*Jasus edwardsii*), with small amounts (less than 1% of the fishery) of eastern rock lobster (*J. verreauxi*) also taken. Giant crab and octopus are bycatch associated with this fishery. Commercial fishers use baited pots to harvest lobsters. Most of the catch comes from the western half of TAS, although the east coast is also fished and is particularly important for the recreational fishery (Fishing TAS, 2023a).

The TAS rock lobster fishery is subject to a fisheries closure period, whereby the fishery outside of the East Coast Stock Rebuilding Zone is open from 15 November to 1 May for females in all State waters. For males the fishery is open from 15 November to 1 September in all waters south of St Helens Point around to Sandy Cape (41°29’) and to 1 October for all other State waters.

Fishing effort near the OA is greatest in the shallow waters surrounding King Island. In all other blocks where fishing was reported, including those overlapped by the OA, fishing was undertaken by less than five vessels per year (**Figure 61**). The OA overlaps with approximately 0.14% of total catch, equating to $77,650 average annual overlap. Fishing effort associated with the TAS rock lobster fishery is expected to be concentrated inshore of the OA, with some limited effort in deeper water along the margin of the OA.



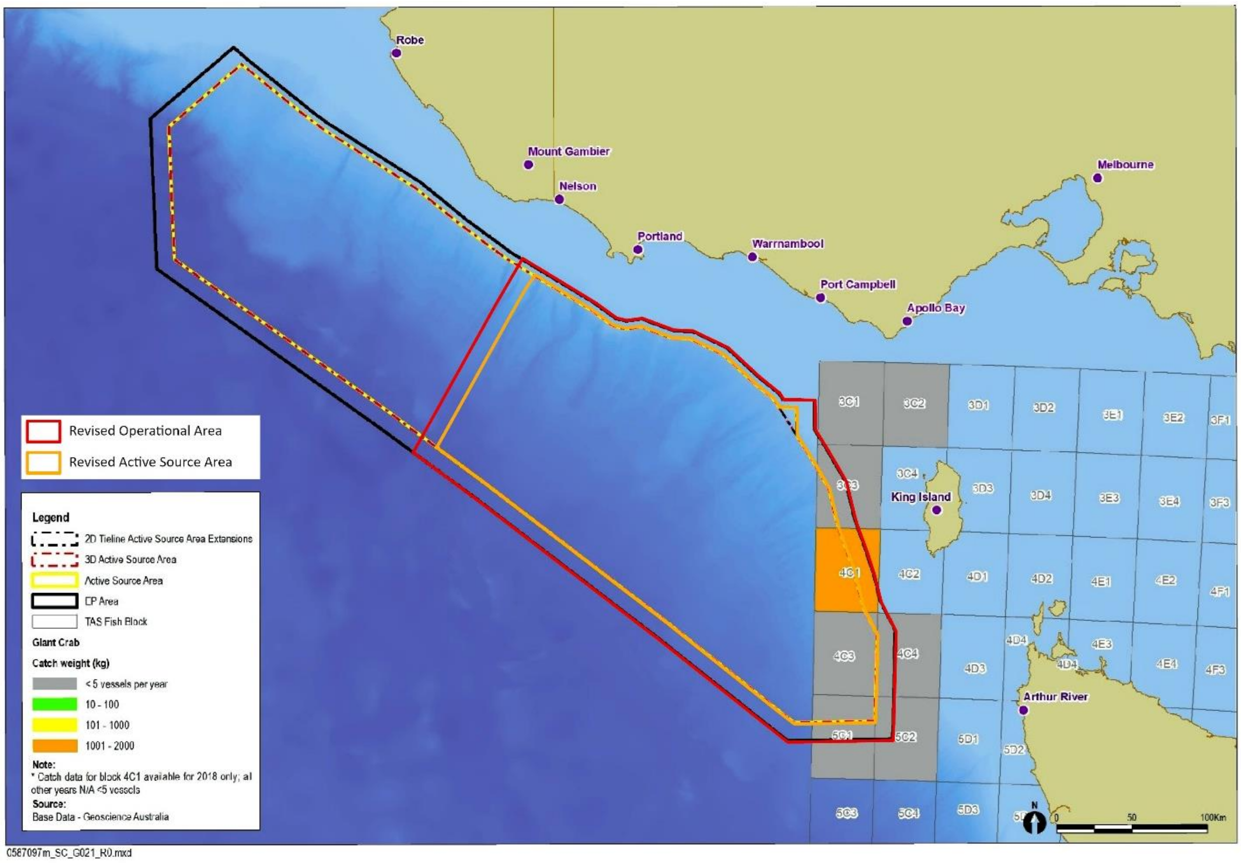
Note: The OA and AA have been revised since this image was produced, with the revised areas overlaid on top.

Figure 61 Fishing Intensity (Estimated Vessel Count) in the Tasmanian Rock Lobster Fishery (2016 – 2020)

4.7.3.4.2 Giant Crab Fishery

The TAS giant crab fishery is a comparatively small fishery. Although the annual harvest is low (20.7t), it has a high landed value of approximately $2 million. The commercial fishery has existed since the early 1990s and has since moved from open access to a limited entry fishery managed by individual transferrable quotas (Fishing TAS, 2023b). The fishery is closed from 15 November to 31 May for females, but open year-round for males.

Fishing effort reported between 2016 and 2020 shows effort has taken place in blocks both on the continental shelf and the continental slope, with fishing in most blocks undertaken by less than five vessels per year. Only in 2018 was a single block targeted by more than five vessels, suggesting this block may receive most effort than others. This area overlaps with the boundary of the OA (**Figure 62**). Based on the mapped giant crab fishing effort, fishing within this fishery primarily takes place in water depths <400 m. Limited fishing effort is understood to occur in deeper waters within the OA, however consultation with TAS giant crab fishers indicated that fishing does sometimes occur at greater depths.



Note: The OA and AA have been revised since this image was produced, with the revised areas overlaid on top.

Figure 62 Fishing Intensity (Estimated Vessel Count) in the Tasmanian Giant Crab Fishery (2016 – 2020)

4.7.3.4.3 Scalefish Fishery

The commercial scalefish fishery is a multi-species and multi-gear fishery predominantly made up of small owner operators. Vessels vary in size and type and a range of different fishing methods are used (e.g. gillnets, hook and line, longline, drop line, squid jig, etc.). Commonly targeted species include banded morwong, southern calamari, octopus, tiger flathead, school whiting, southern garfish, wrasse, Gould's squid, bastard trumpeter, blue warehou, silver warehou, flounder, silver trevally, striped trumpeter, and small pelagics (Fishing TAS, 2023c), with the highest catches in 2020/21 reported for Gould's squid, southern calamari, tiger flathead, and eastern school whiting.

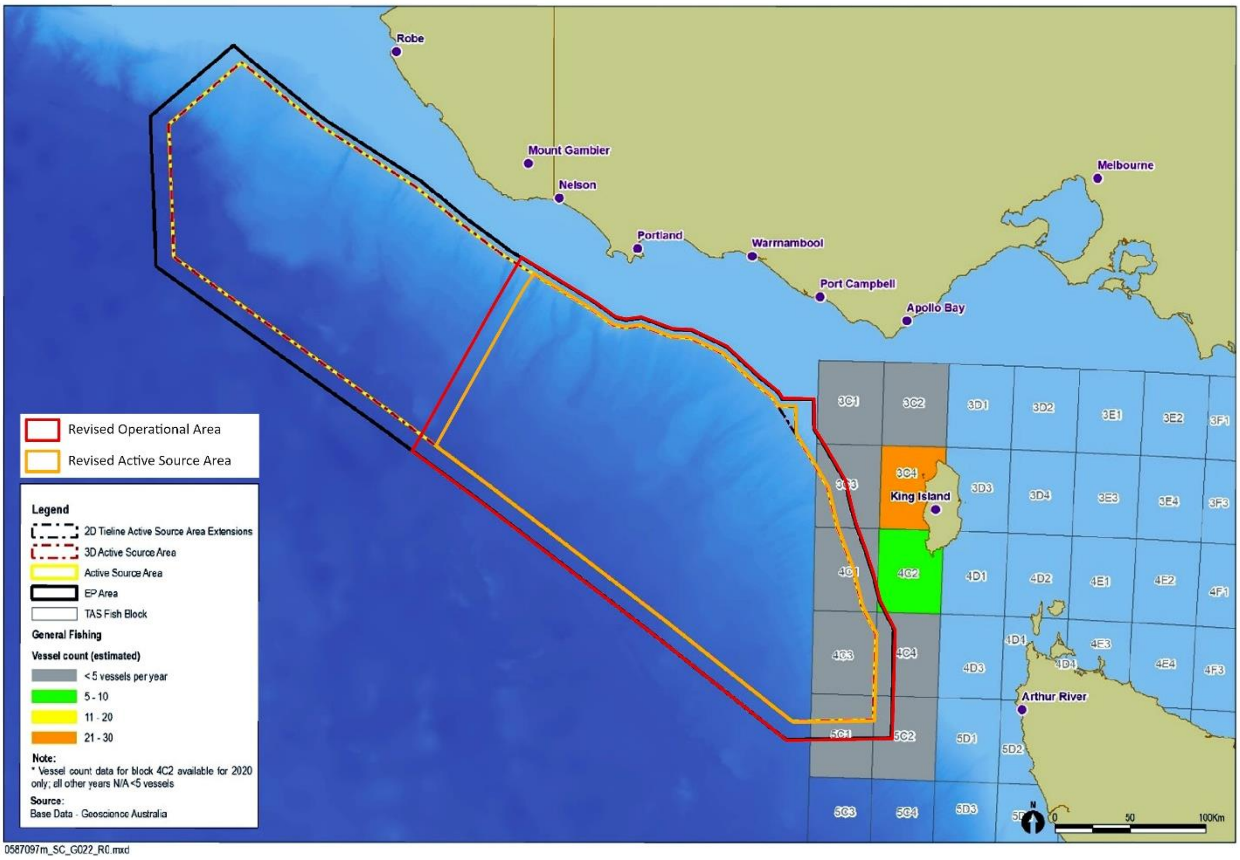
The TAS scalefish fishery is open year-round, except for during the following species-specific seasonal closures:

- Banded morwong – Closed from 1 March to 30 April;
- Southern calamari – Closed from 1 October – 31 October (north coast) and 15 October – 14 November (east coast);
- Garfish – Closed from 15 November – 14 December (south) and 15 January – 14 February (north); and
- Striped trumpeter – Closed from 1 September – 31 October.

The TAS scalefish fishery is managed through capped licence numbers, closed seasons, gear restrictions, size limits, and trip limits. There are a variety of types of licences that allow access to a specific species and the use of specific gear to take that species. These include ten gear type licences, three species licences, and three other licences.

Since the early 1990s, annual commercial catch for the major scalefish species has generally declined, with this decline explained in part by changed targeting practices and market demand, declines in species abundance and biomass, the introduction of the Scalefish Fishery Management Plan in 1998, and the transfer for the Southern Shark Fishery to the Commonwealth in 2000 (Fraser *et al*., 2022). In 2019/20, total catch was 293t. The total number of licences in 2022 was 344 gear-type licences, 113 species licences, and 1,440 other licences, however, only 20 – 50% of licences are active depending on the type (Fraser *et al*., 2021).

Fishing effort near the OA from 2016 – 2020 was focused on the waters surrounding Kind Island, with fishing in all other blocks undertaken by less than five vessels per year. The OA overlaps with low fishing intensity blocks along the eastern boundary, with a small overlap with fishing block 4G2 within which 5 – 10 vessels were reported to have fished (**Figure 63**). The OA overlaps approximately 0.2% of the total catch, equating to $38,670 average annual revenue overlap.



Note: The OA and AA have been revised since this image was produced, with the revised areas overlaid on top.

Figure 63 Fishing Intensity (Estimated Vessel Count) in the Tasmanian Scalefish Fishery (2016 – 2020)

4.7.3.4.4 Abalone Fishery

The TAS abalone fishery is the largest wild abalone fishery in the world, providing approximately 25% of the annual global production of wild caught abalone. The fishery mainly targets blacklip abalone, with greenlip abalone accounting for 5% of the total wild harvest. Commercial abalone divers harvest the abalone by hand (DPIPWE, 2018).

The TAS abalone fishery is open year-round, however, at times, sub-blocks of the commercial abalone fishery are closed to control the total amount of abalone harvested in an area in the interest of resource sustainability; these are referred to as 'catch-ups'. The commercial fishery has limited entry via a cap on dive licences and is managed using a system of size limits, total allowable catch, and regional catch-ups. Catch-ups are set for the following quota year, which aligns with the calendar year (DPIPWE, 2018). Annual catch within the TAS abalone fishery has continued a downward trend since approximately 2010 (Mundy and McAllister, 2022).

There is no overlap between the OA and the TAS Abalone Fishery, although the fishery may overlap with the EMBA.

4.7.3.4.5 Commercial Dive Fishery

The TAS commercial dive fishery selectively harvests three key species by hand from small vessels: shortspined sea urchin (*Heliocidaris erythrogramma*), wavy periwinkle (*Lunella undulata*) and longspined sea urchin (*Centrostephanus rodgersii*). The fishery is predominantly owner-operated, with around 53 licences (Fishing TAS, 2023d).

As the two urchin species spawn at different times of the year, the urchin fishery operates almost year-round. Harvesting of shortspined urchin peaks from August to January, longspined sea urchin from December to July, and wavy periwinkle from August to November (Fishing TAS, 2023d).

There is no overlap between the OA and the TAS commercial dive fishery, although the fishery may overlap with the EMBA.

4.7.3.4.6 Marine Plants Fishery (formerly Kelp Fishery)

The marine plants fishery covers the harvest of marine plants including kelp, seaweed, seagrasses and algae. No marine plants may be harvested directly from the water, expect in the Undaria fishery. The fishery is therefore comprised of a commercial beach-cast harvest, and a commercial diving harvest for Undaria. For the commercial beach-cast harvest, licensed harvesters hand-collect beach-cast seaweed. Bull kelp (*Durvillaea potatorum*) is the main harvest species, primarily from King Island, Marrawah, and Grainville Harbour. Licensed commercial divers hand collect Undaria from East Coast waters under the authority of a fishing licence.

There is no overlap between the OA and the TAS marine plants fishery, although the fishery may overlap with the EMBA.

4.7.3.4.7 Octopus Fishery

The Tasmanian octopus fishery operates off the north coast of TAS and in the Bass Strait. The fishery primarily targets pale octopus with maori octopus and gloomy octopus caught as by-catch. The fishery has been a sole operator fishery since its commencement in 1980, with two vessels operating in the fishery. Unbaited octopus pots are deployed at fishing grounds, with retrieval occurring approximately 3 – 6 weeks later (Krueck *et al.,* 2021).

Commercial fishing for octopus is currently restricted to the East Bass Strait and West Bass Strait fishing zones, with the remainder of TAS waters classified as developmental and may be opened to fishing. In 2019/20, almost all of the octopus catch in the fishery was taken from within two fishing blocks east of King Island; however, historically productive fishery areas include north-east of Flinders Island (Krueck *et al.,* 2021). It is unlikely that this fishery overlaps with the EMBA based on recent fishing effort. There is no overlap between the OA and the TAS octopus fishery.

4.7.3.4.8 Scallop Fishery

The TAS scallop fishery extends to 200 NM from the TAS coast, except for Bass Strait, where its jurisdiction covers 3 – 20 NM offshore. As of 31 December 2022, the TAS scallop fishery is closed. Statewide exploratory commercial scallop surveys will commence from 1 April 2023, the aim of which are to identify beds of scallops that might be considered for opening during the 2023 season or a future season (Fishing TAS, 2023e).

There is no overlap between the OA and the TAS scallop fishery and it is unlikely that this fishery overlaps with the EMBA.

4.7.3.4.9 Shellfish Fishery

The TAS commercial shellfish fishery selectively hand-harvests (e.g diving from small vessels or wading) four species of shellfish: pacific oysters (statewide), native oyster (Georges Bay), Venerupis clams (Georges Bay North Clam Zone), and Katelysia cockles (Ansons Bay Cockle Zone).

Harvest locations are restricted to areas that were historically identified through a research and permitting process, as being best able to support a fishery. There is no overlap between the OA and the TAS shellfish fishery, and it is unlikely that this fishery overlaps with the EMBA.

4.7.3.5 South Australian Managed Fisheries

Commercial fisheries within South Australian State waters are regulated by the Fisheries and Aquaculture division of the Department of Primary Industries and Regions, South Australia (**PIRSA**). The purpose of PIRSA is to grow primary industries and drive regional development. Management of South Australian fisheries are achieved through the administration of the Fisheries Management Act 2007, the management of licences and registrations, preparation of fisheries management plans (thought collaboration with industry and other stakeholders), and support of scientific research and innovation through the South Australian Research and Development Institute (**SARDI**) (PIRSA, 2023).

SARDI is the South Australian Government's principal primary industries research institute, providing policy-driven applied research. Research carried out by SARDI has supported PIRSA's fisheries management decisions for ongoing ecological sustainability of South Australian commercial fisheries and has resulted in higher economic returns (SARDI, 2017).

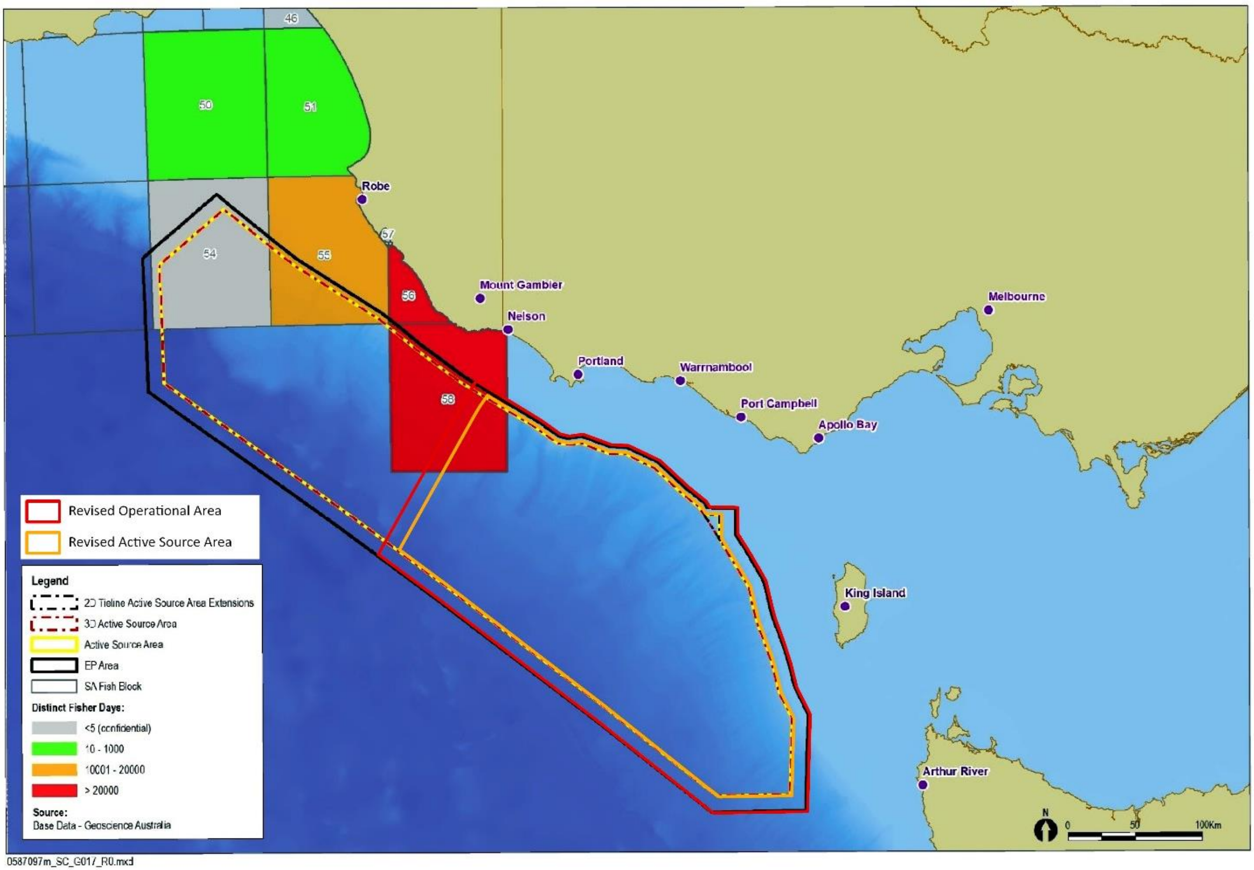
South Australia State-managed fisheries that overlap with the OA and EMBA are discussed in **Section 4.7.3.5.1 – Section 4.7.3.5.6**.

4.7.3.5.1 Rock Lobster Fishery

The South Australian rock lobster fishery is separated into two management zones: the Southern Zone (all marine waters between the mouth of the Murray River and the VIC border, and the Northern Zone (all marine waters between the mouth of the Murray River and the Western Australia border. The OA primarily overlaps the Southern Zone of the fishery, with negligible overlap with the boundary of the Northern Zone in offshore waters. There are 180 commercial licences within the Southern Zone, with lobsters caught using steel-framed pots that are set overnight and retrieved at first light. The fishery within the Southern Zone is closed from 1 August to 14 September. The fishery targets southern rock lobster, with giant crab and octopus also permitted to be landed and sold (Linnane *et al*., 2022).

In 2020, the total commercial catch within the Southern Zone was 1,289t, with an effort of 775,014 potlifts (Linnane *et al*., 2022).

Fishing effort data is available in coarse resolution (60 NM) blocks only. In the five year period between 2016 and 2020, the greatest effort was undertaken in blocks 56 and 58, with over 20,000 distinct fisher days reported in these blocks. The OA overlaps with block 58. A slightly lower level of effort was reported in block 55 (10,001 – 20,000 days) (**Figure 64**). The pattern of fishing effort (**Figure 64**) suggests that waters offshore from Robe to the South Australian/VIC border are the most fished in the Southern Zone. Given the very coarse grid resolution and the preferred water depths of lobsters (up to 200 m (PIRSA, 2021)), it is expected that fishing effort takes place primarily along the northern edge of the OA and in waters further inshore. Some fishing for deeper water lobster mya occasionally occur in the OA.



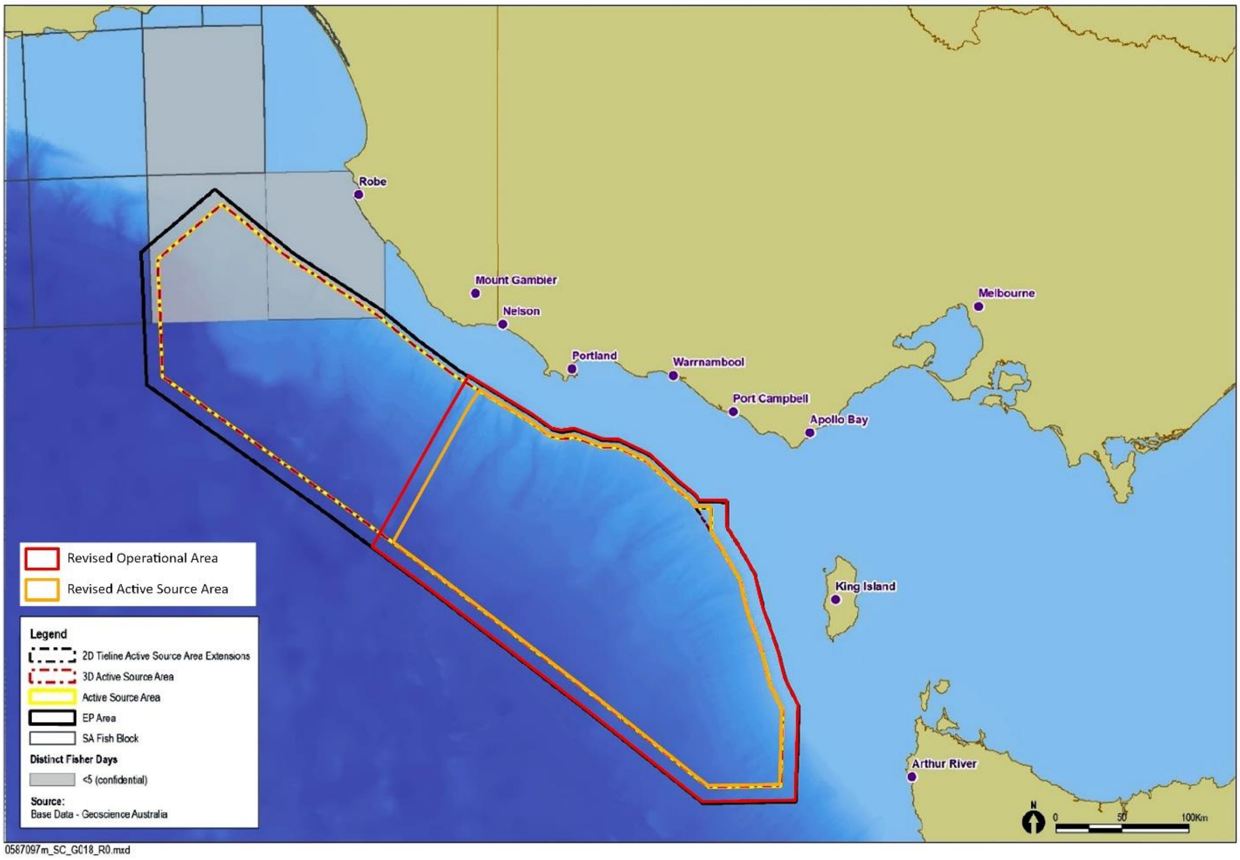
Note: The OA and AA have been revised since this image was produced, with the revised areas overlaid on top.

Figure 64 Fishing Intensity (Distinct Fisher Days) in the South Australian Rock Lobster Fishery (2016 – 2020)

4.7.3.5.2 Giant Crab Fishery

South Australia's giant crab fishery is linked to the rock lobster fishery. Deepwater traps are used like those used in the rock lobster fisher. The South Australian Southern Zone giant crab fishing season runs between 1 October and 30 April. Females with external eggs cannot be kept and must be returned to the water as soon as possible.

Between 2016 and 2020, there was no fishing effort reported for the giant crab fishery within the OA, with all fishing effort ocurring at low levels offshore from Robe and towards Kangaroo Island (**Figure 65**). Given that giant crab occur at depths ranging from 20 to 600 mm with the highest population densities found at the edge of the continental shelf at depth of 140 – 270 m, the greatest effort is expected to occur outside of the OA.



Note: The OA and AA have been revised since this image was produced, with the revised areas overlaid on top.

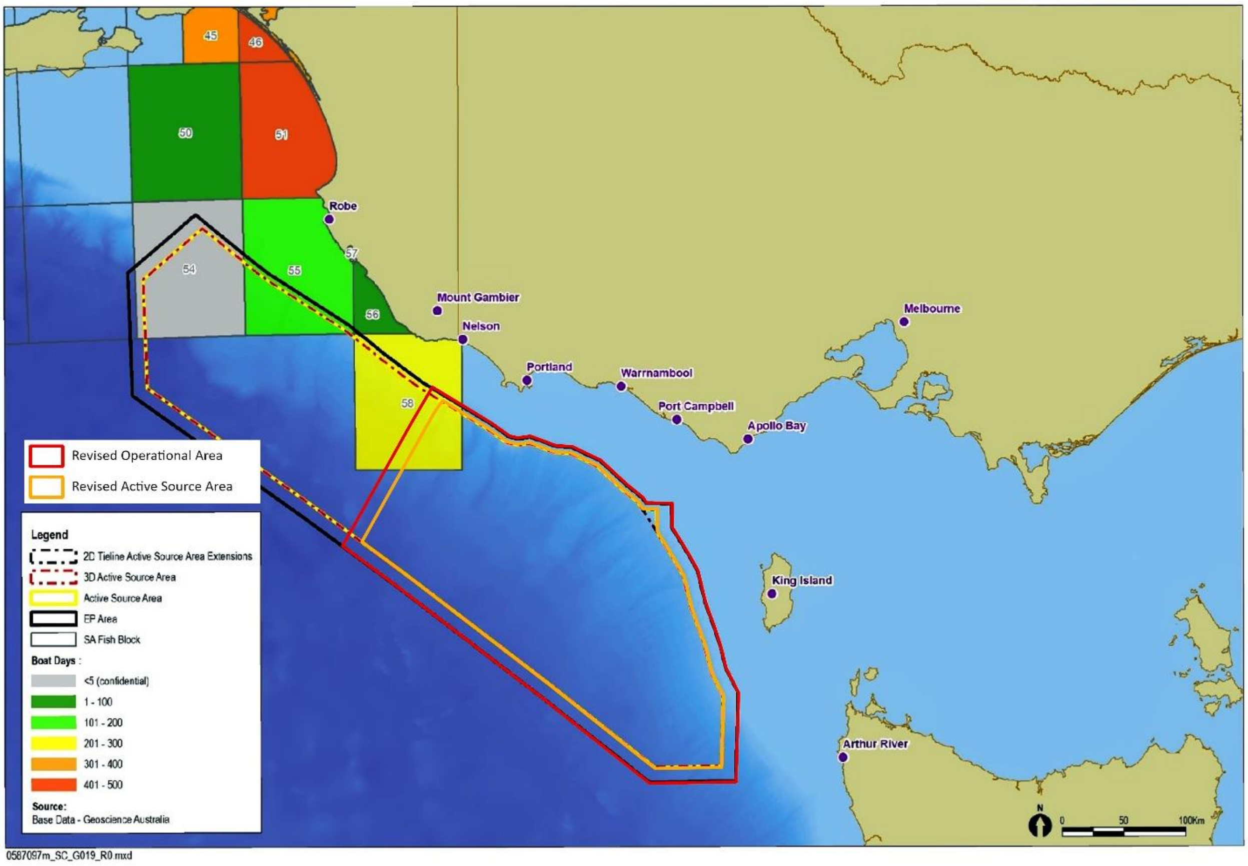
Figure 65 Fishing Intensity (Distinct Fisher Days) in the South Australian Giant Crab Fishery (2016 – 2020)

4.7.3.5.3 Marine Scalefish Fishery

The South Australian marine scalefish fishery covers all coastal waters of South Australia between the Western Australia and VIC borders. It is a multi-species and multi-gear (hook and line, longline, haul nets, mesh nets, and jigs) fishery that covers more than 60 species of scalefish. Fishign within this industry occurs year-round. The main species taken within this fishery are King George whiting, southern garfish, and southern calamari, with these four species making up 60% of the total fishery production weight and 70% of the total fishery value (PIRSA, 2023a). In 2020, there were more than 300 active licence holders within the fishery (Smart *et al.*, 2022).

Major changes to the fishery were implemented on 1 July 2021 with the goal of strengthening the long-term financial and ecological sustainability of the industry. Key elements of the reform include the establishment of four fishing zones (West Coast, Spencer Gulf, Gulf St Vincent and Kangaroo Island, and South East), the establishment of individual transferrable quota to manage catch limits, and separation of the commercial taking of vongole and sardine from the marine scalefish fishery with the creation of new fisheries under their own regulations (PIRSA, 2023b).

Histroically, effort within this fishery was widespread across most of the State's marine fishing areas, however, since 2000, fishing effort is largely concentrated within the gulfs near Adelaide. Between 2016 and 2020, effort in fishing blocks for the South Australian Marine Scalefish Fishery was greatest in the Coorong Coast between Victor Harbour and Cape Jaffa (in excess of 400 boat days in blocks 46 and 51), with effort decreasing with increasing distance from shore. The OA overlaps with fisheries block 58, where fishing effort in 2016 – 2020 was 201 – 300 boat days (**Figure 66**).



Note: The OA and AA have been revised since this image was produced, with the revised areas overlaid on top.

Figure 66 Fishing Intensity (Boat Days) in the South Australian Marine Scalefish Fishery (2016 – 2020)

4.7.3.5.3.1 Sardine Fishery

The South Australian Sardine Fishery is a component of the Marine Scalefish Fishery that targets the Australian sardine and Australian anchovy. The fishery covers all South Australian waters out to the 200 NM EEZ. Fish are caught using the purse seine method using sardine nets. Sardines are primarily used as feed for the southern bluefin tuna ranching industry, with small amounts also sold for human consumption and as recreational bait (PIRSA, 2014).

The fishery is extremely visible, based in the line of sight of main towns (PIRSA, 2014). As a result, there will not be any overlap between the OA and Sardine Fishery, although there may be overlap with the EMBA in coastal waters along the South Australian coastline.

4.7.3.5.4 Abalone Fishery

The South Australian commercial abalone fishery is divided into three zones: Western Zone, Central Zone, and Southern Zone. The fishery targets blacklip abalone and greenlip abalone, during the fishing season which runs from 1 October to 30 September (Burnell *et al*., 2022).

Following the detection of abalone viral ganglioneuritis at Cape Nelson (VIC) and some NSW abalone processors in May 2021, temporary restrictions were put in place to keep South Australians waters free of the disease. There are currently no new licences available for commercial fishing in the South Australia abalone fishery (PIRSA, 2023c).

As this fishery is a dive-based fishery, there will be no overlap with the OA, however, some overlap may occur between the fishery and the EMBA in coastal locations of Southern Australia.

4.7.3.5.5 Charter Boat Fishery

The South Australian Charter Boat Fishery provides recreational fishers (clients) with access to South Australian fisheries resources through the provision of purpose-built vessels, experienced operators, and modernised technology. Clients typically use rod and lines, but are also permitted to use bait pumps, cockle and crab rakes, crab nets and lobster pots. Operators can provide additional services such as diving expeditions, ecotours and passenger trips. The fishery can operate in all coastal waters, including the gulfs and bays from the borders of South Australia/Western Australia and South Australia/VIC. The main species targeted in this fishery are snapper, King George whiting, bight redfish, Western Australian salmon, snook, silver trevally, southern bluefin tuna, southern calamari, and southern garfish. Although fishing charters operate within water depths greater than 250 m, these waters represent a small proportion of fishing destinations (0.63% of mean annual effort), with most activity occurring in inshore regions where water depths are 50 m or less (76% of charter activities) (Durante *et al*., 2022).

Due to the offshore nature of the OA, it is unlikely that the charter boat fishery will overlap with the OA, however, this fishery may overlap with the EMBA.

4.7.3.5.6 Miscellaneous Fishery

The South Australian Miscellaneous Fishery includes species that are not in management arrangements of existing commercial fisheries, specialised fisheries, and multiple types of fishing gear. Many of the fisheries are low production, low value, or both. Species taken by the Miscellaneous Fishery include sea urchins, scallop, native oyster, giant crab, Australian salmon, beachcast seagrass and macro-algae, Eyre golden perch, Welch's grunter, and Barcoo grunter (PIRSA, 2023d).

There may be some overlap between the OA and Miscellaneous Fishery, particularly when giant crab is targeted (**Section 4.7.3.5.2**). Miscellaneous Fisheries will likely also overlap with the EMBA.

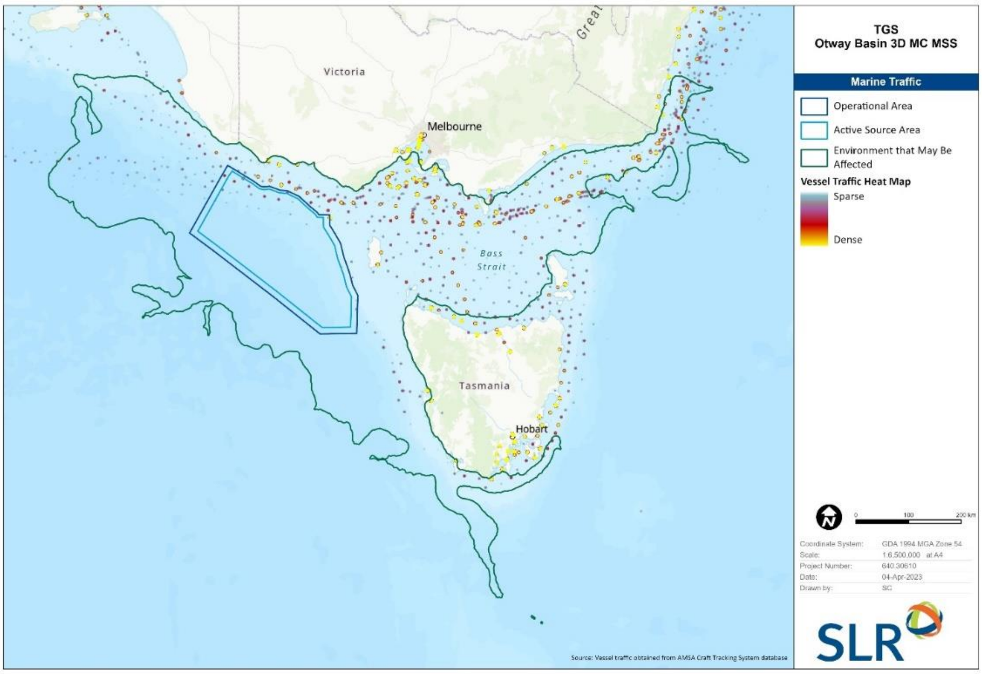
4.7.3.6 New South Wales Managed Fisheries

The NSW Department of Primary Industries manages fisheries within NSW State waters. The NSW State-managed fisheries overlapping the EMBA include the Ocean Trawl Fishery, Ocean Trap and Line Fishery, Ocean Hauling Fishery, Lobster Fishery, Abalone Fishery, Sea Urchin and Turban Shell Fishery and Developmental Commercial Fisheries. There is no overlap of these fisheries with the OA.

Due to the small overlap of the EMBA with NSW waters and that a marine fuel spill is highly unlikely, NSW fisheries have not been described further within this EP.

4.7.4 Shipping

Shipping activity in the SEMR encompasses cargo shipping and passenger shipping (passenger service and ferry service). The SEMR is home to some of Australia's busiest shipping routes including the Bass Strait, east-west and west-east international trading routes. A major shipping port exists at Portland, approximately 45 km north of the OA. Vessel traffic within the vicinity of the OA is shown in **Figure 67.**



Note: The above map only shows the vessels that have AIS onboard, vessels which don't have AIS will not be shown.

Figure 67 Marine Traffic Density (March 2022 – February 2023)

4.7.5 Oil and Gas Activities

4.7.5.1 Petroleum Titles and Production

The region currently supports a number of industries including petroleum exploration and production. Other exploration activities, such as seismic surveys, may occur within and surrounding the OA over the duration of this EP. The Thylacine platform is located within permit T/L2 which partially overlaps the OA.

Petroleum titleholders with titles that are located within the OA are listed in **Table 36** and presented in **Figure 68**.

Table 36 Petroleum Titles overlapping the OA

Permit	Permit Type	Petroleum Operator
VIC/P79	Exploration permit	ConocoPhillips Australia SH2 Pty Limited
T/30P	Exploration permit	Beach Energy (Operations) Limited
T/49P	Exploration permit	ConocoPhillips Australia SH1 Pty Limited
T/L2	Production licence	Beach Energy (Operations) Limited
T/L3	Production licence	Beach Energy (Operations) Limited
T/L4	Production licence	Beach Energy (Operations) Limited

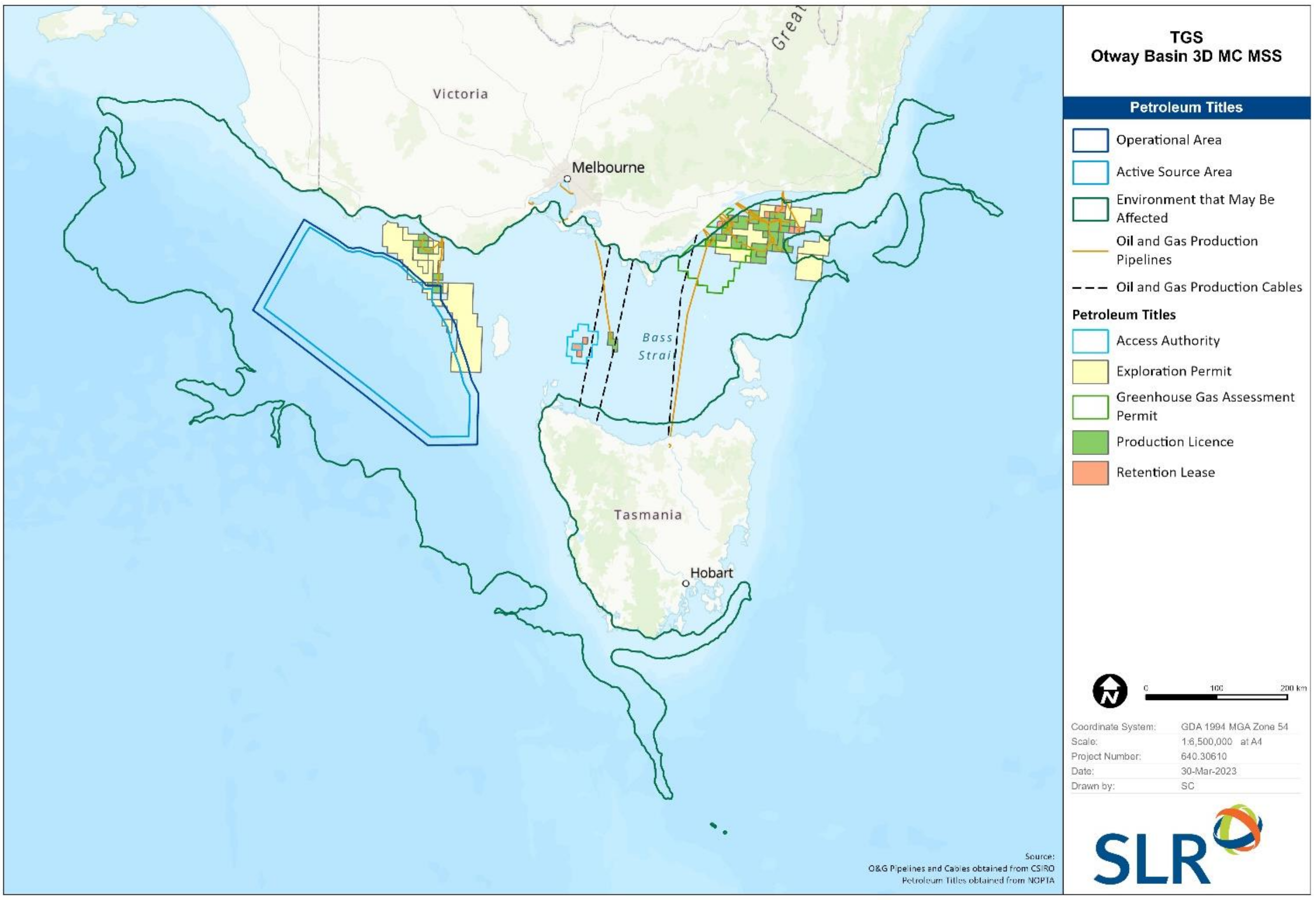


Figure 68 Offshore Petroleum Titles in the vicinity of the OA and EMBA

4.7.6 Submarine Cables

Of relevance to the OA is the INDIGO cable system. This cable system spans a total of 9,200 km and consists of two distinct cable projects; the Indigo West project and the Indigo Central project, the latter of which is of relevance to the Otway Basin 3D MC MSS. The Indigo Central project consist of 4,600 km of cable connecting Perth to Sydney and overlaps directly with the OA (**Figure 69**).

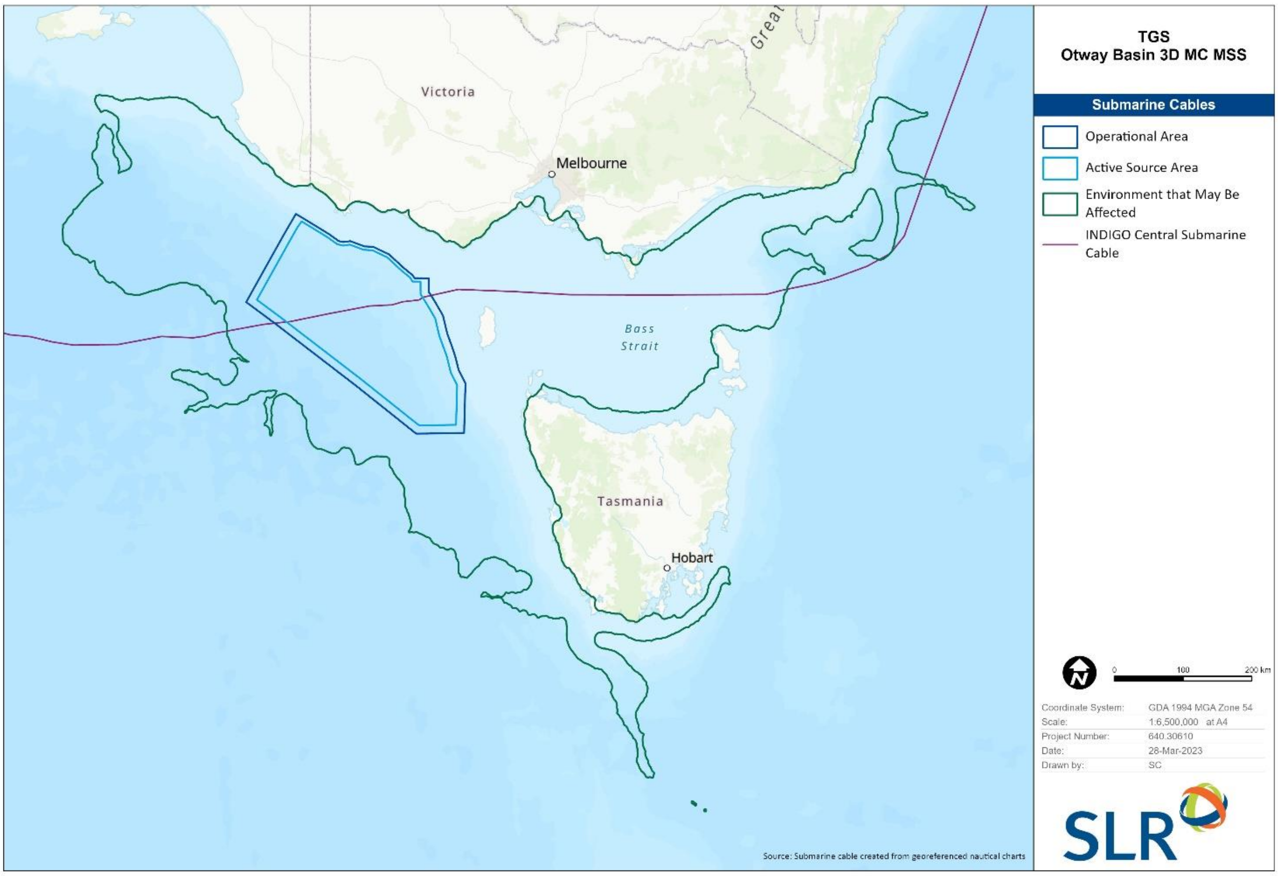

Figure 69 Submarine Cables of Relevance to the OA

4.7.7 Defence Activities

There are many areas throughout Australia that are either confirmed as, or suspected of being, affected by unexploded ordnance (**UXO**) as a result of military activities by Australian and allied military forces, particularly during World War II. UXO include any explosive ordnance (e.g. ammunition, projectiles, mortars, bombs, grenades, torpedos, etc) that have been fired and failed to function as intended (Department of Defence, 2018). Mustard gas (sulphur mustard) was the most common type of chemical warfare agent dumped at sea (Plunkett, 2018).

The Department of Defence operate military firing practice and exercise areas at various locations around Australia. A defence training area and defence practice area lie off the southeast coast of Kangaroo Island, 190 km from the OA.

The Department of Defence maintains a record of sites confirmed as, or reasonably suspected of, being affected by UXO. A search of the Department of Defence's UXO map confirmed eight UXO sites occur in the vicinity of the OA including:

- 1191 Coastal Waters – UXO Category. Also Kangaroo Island 009, includes Site ID 1192
- SDG064 Sea Dumping – Victorian Coast. This is an area used for the dumping at sea of ordnance and other items. This site was used for the dumping at sea of ammunition including 59 cases of weapons. UXO Category: Other Sea Dumping Sites
- SDG135 Sea Dumping – Victorian Coast. This site is an area used for the dumping at sea of ordnance and other items. This site was used for the dumping at sea of ammunition including inert metal missile parts. UXO Category: Other Sea Dumping Sites.
- SDG110 Sea Dumping – Bass Strait. This site is an area used for the dumping at sea of ordnance and other items. This site was used for the dumping at sea of ammunition including 2331 boxes of detonators and 144 boxes of explosives. UXO Category: Other Sea Dumping Sites;
- SDG136 Sea Dumping – Victorian Coast. This site is an area used for the dumping at sea of ordnance and other items. Site of post WWII Sea Dumping Activity. UXO Category: Other Sea Dumping Sites;
- SDC006 Sea Dumping – Off King Island. This site is an area used for the dumping at sea of ordnance and other items. This site was used for the dumping of chemical munitions including 1,634 tons of chemical munitions in 1948. UXO Category: Other Sea Dumping Sites;
- SDG087 Sea Dumping – King Island. This site is an area used for the dumping at sea of ordnance and other items. This site was used for the dumping at sea of ammunition including cartridges, projectiles, and fuses. UXO Category: Other Sea Dumping Sites;
- 1052 – King Island. This site was used during 1958 as an Air to Air Firing Range. UXO Category: Slight Potential.

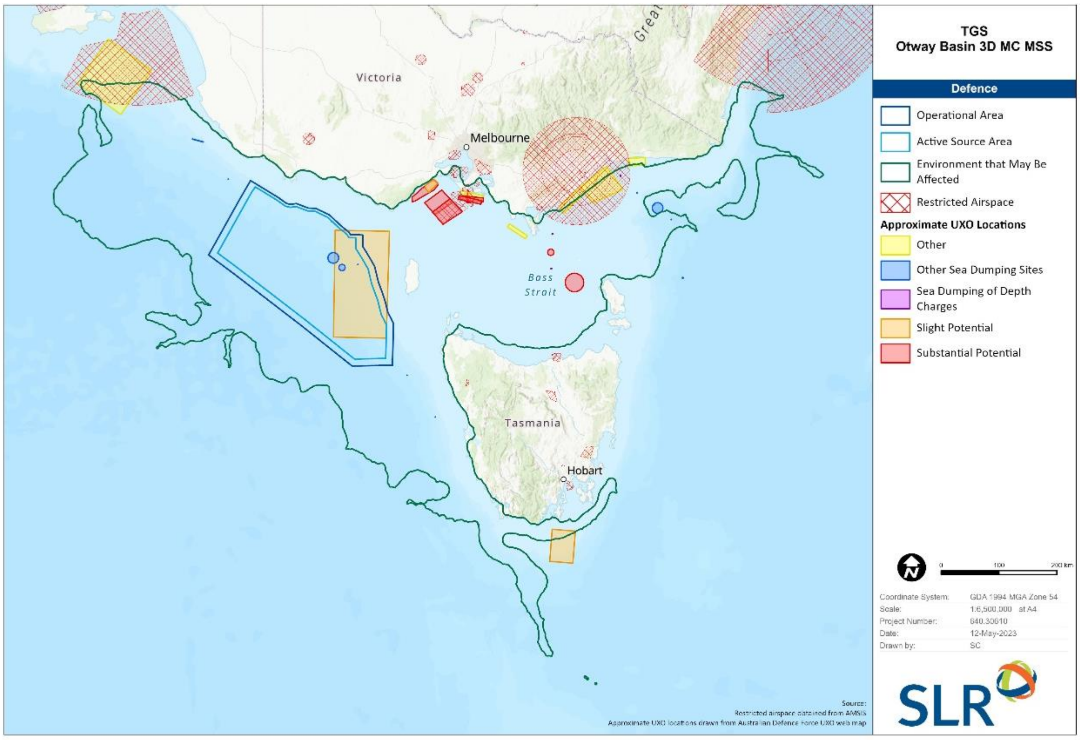

Figure 70 Defence Activities and UXOs Within the OA and EMBA

4.7.8 Research Activities

Several research organisations conduct research activities throughout South Australian, VIC, and TAS marine waters. A summary of research organisations that potentially have interests in the OA is provided below. **Section 5** outlines the consultation undertaken with research organisations, with full correspondence provided in **Appendix H**.

- **Blue Whale Study Inc**. – The study area of Blue Whale Study Inc. covers the continental shelf and support slope waters between 40°30'S, 144°E and 33°20'S, 131°07'E, from western Bass Strait to the eastern GAB. The primary interest of Blue Whale Study Inc. is the ecology of the pygmy blue whale in the Bonney Upwelling and surrounding waters of south-east Australia. Aerial surveys and photo-identification are core research priorities of the group, although other works include deployment and tracking of tags (e.g. satellite tags, suction-cup attached dive loggers), and modelling of feeding habitat in the region.

  Blue Whale Study Inc. provide consultation services to government and industry that operated in whale feeding areas and marine mammal monitoring and research services to industry; control measures for the Otway Basin 3D MC MSS regarding marine mammals have been developed in consultation with Blue Whale Study Inc (Blue Whale Study Inc., 2023).

- **Deakin University** – Deakin University is a public university in VIC, with main campuses in Melbourne's Burwood suburb, Geelong Waurn Ponds, Geelong Waterfront, and Warrnambool. Students undertaking research for their university studies may utilise coastal waters along the coastline inshore of the OA.

- **Australian Right Whale Research (ARWR)** – ARWR conducts research on southern right whales, covering research topics such as population biology, photo identification and underwater acoustics at Head of Bight and Fowlers Bay in the GAB. Since 1991, ARWR have established an ongoing annual population monitoring program at the Head of Bight southern right whale aggregation grounds.

- **University of Tasmania** – The University of Tasmania is a public research university, located in Hobart, TAS. Students of the University of Tasmania conduct research in the marine environment. The Institute for Marine and Antarctic Studies (**IMAS**) is a teaching and research institute of the University.

- **Commonwealth Scientific and Industrial Research Organisation (CSIRO)** - an Australian Government agency responsible for scientific research across a range of disciplines including technology, natural environments, health and medical, environmental impacts, etc.

- **Bureau of Meteorology (BOM)** - an agency of the Australian Government that is responsible for providing weather services to Australia and surrounding areas.

- **Monash University -** a public research university based in Melbourne, VIC. Students undertaking research for their university studies may utilise coastal waters along the coastline inshore of the OA.

A search of the Parks VIC, Australian Maritime Safety Authority (**AMSA**) and Australian Hydrographic Office (**AHO**) Notice to Mariners systems was carried out in order to identify any research equipment deployed in the marine environment that may be of relevance to the OA. No Notice to Mariners were found in relation to the OA.

4.8 Periods of Peak Sensitivity or Activity within the OA

A summary of distribution, activities and peak periods for significant species and other relevant activities that may occur annually within or close to the OA is provided in **Table 37** below.

Table 37 Timing of Key Activities Relevant to the OA and the Surrounding Area

Sensitivity	Jan	Feb	March	April	May	June	July	Aug	Sept	Oct	Nov	Dec
Otway Basin 3D MC MSS proposed timing												
Sharks and rays												
Great white shark foraging												
Marine mammals												
Humpback whale migration												
Pygmy blue whale (presence)					Depart upwelling system							
Southern right whale (presence)												
Sperm whale foraging[5]												
Marine reptiles												
Leatherback turtle foraging												
Marine birds												
Little penguin (presence)												
Albatrosses foraging and breeding												
Petrels foraging and breeding												
Orange-bellied parrot wintering (non-breeding) (south-east Australia)												
Fish Spawning												
Blue Warehou												
Blue Grenadier												
Orange Roughy												

Sensitivity	Jan	Feb	March	April	May	June	July	Aug	Sept	Oct	Nov	Dec
Striped Trumpeter												
School Shark												
Giant Crab												
Greenlip abalone												
Blacklip abalone												
Southern Rock Lobster												
Scallop												
Snapper												
Squid												
Other demersal fish species (sustainable stock)												
Other pelagic fish species (sustainable stock)												
Commonwealth Fisheries												
Southern and Eastern Scalefish and Shark Fishery												
Bass Strait Central Zone Scallop Fishery												
Southern Squid Jig Fishery												
Southern Bluefin Tuna Fishery												
Small Pelagic Fishery (Western)												
Victorian Fisheries												
Ocean Scallop Fishery												
Rock Lobster Fishery (Western Zone) – up to 200 m depth – **Females**						Closed 1 Jun-15 Nov						

Sensitivity	Jan	Feb	March	April	May	June	July	Aug	Sept	Oct	Nov	Dec
Rock Lobster Fishery (Western Zone) – up to 200 m depth – **Males**									Closed 15 Sep-15 Nov			
Giant Crab Fishery – 140 m to 300 m depth – **Females**						Closed 1 Jun-15 Nov						
Giant Crab Fishery – 140 m to 300 m depth – **Males**									Closed 15 Sep-15 Nov			
Wrasse Fishery – up to 40 m depth												
Abalone Fishery – up to 30 m depth	Fishing only permitted between sunrise and sunset											
South Australian Fisheries												
Rock Lobster Fishery (Southern Zone) – up to 200 m depth								Closed 1 Aug – 14 Sep				
Giant Crab Fishery (Southern Zone) – 100 m to 200 m depth					Closed 1 May - 30 Sep							
Scalefish Fishery (multi-species)												
Tasmanian Fisheries												
Giant Crab Fishery – 110 m to 180 m depth	Females: closed 1 Jun-15 Nov; Males: open all year-round											
Rock Lobster Fishery – up to 150 m depth												
Scalefish Fishery (multi-species)												
Peak Period												

5 Relevant Persons Consultation

Consultation with relevant persons is an integral component of the project development and planning phase of any potentially impacting activity, and TGS acknowledges that undertaking an effective consultation programme that extends for the duration of the EP is critical to the success of the Otway Basin 3D MC MSS. TGS is aware of and understands the requirements regarding appropriate consultation, as defined under the Environment Regulations and has developed an inclusive and ongoing relevant persons consultation process that will extend beyond the completion of the Otway Basin 3D MC MSS for the duration of the EP.

This section demonstrates that TGS has undertaken an extensive consultation programme in accordance with Division 2.2A and Regulation 10A(g) of the Environment Regulations and that the measures (if any) TGS has adopted, or proposes to adopt, because of the consultation process are appropriate. TGS is also committed to continuing consultation throughout the acquisition of the Otway Basin 3D MC MSS and will consult with relevant persons for the duration of the EP.

To assist with developing an effective consultation programme that informs, provides sufficient information and builds capacity in relevant persons, to the extent that they understand the potential risks and impacts associated with the proposed Otway Basin 3D MC MSS on their functions, interests and activities, TGS has been guided by Division 2.2A of the Environment Regulations, NOPSEMA Guidance Document N-04750-GL2086 A900179 (Consultation in the course of preparing an environment plan, NOPSEMA 2023) (**the Guidance Document**), and the instructive reasons given by the Full Federal Court of Australia, in its appeal decision *Santos NA Barossa Pty Ltd v Tipakalippa* [2022] FCAFC 193 on 2 December 2022. In addition, the general principles for public participation regarded as underpinning good practice (IAP2, 2016), as well as other appropriate consultation frameworks[8] have been consulted.

5.1 Regulatory Requirements and Guidelines

In accordance with sub regulation 11A(2) of the Environment Regulations, TGS is required to consult with ‘relevant persons’ who may be affected by the Otway Basin 3D MC MSS and provide sufficient information to allow the relevant person to make an informed assessment of the possible consequences that may arise from the proposed activities on their functions, interests or activities. In addition, TGS must provide a reasonable period of time to assess the activity being proposed (i.e. the Otway Basin 3D MC MSS) and respond accordingly to raise any objections or claims they may have. Issues and concerns raised may relate to environmental, social, economic and other factors. It is expected that any such objections or claims raised are considered by TGS and, wherever practicable, incorporated into the management and control measures of the proposed Otway Basin 3D MC MSS as a component of this EP. TGS will extend this further through continuing consultation where any claims raised even during the acquisition of the Otway Basin 3D MC MSS would be assessed and if any change to management or control measures is required, would be done so through the management of change process.

The parties considered as ‘relevant persons’ and who have been engaged with as part of the consultation programme are defined within **Section 5.3** and a full list of all persons consulted is provided in **Appendix G**. For the purpose of this EP, the definition of a ‘relevant person’ followed the direction and intent of the Guidance Document and relevant paragraphs cited by the Appeal Decision. This ensured that relevant persons were identified on the basis of their functions, interests and activities in relation to the Otway Basin 3D MC MSS.

[8] https://www.dmp.wa.gov.au/Stakeholder-and-community-22456.aspx

In developing this EP and the corresponding relevant persons consultation, TGS has considered the requirements of the following:

Relevant case law:

- *Tipakalippa v National Offshore Petroleum Safety and Environmental Management Authority* (No 2) [2022] FCA 1121 (**the Primary Decision**); and
- *Santos NA Barossa Pty Ltd v Tipakalippa* [2022] FCAFC 193 (**the Appeal Decision**).

State Governments (VIC, TAS, NSW, SA) Department of Transport:

- Offshore Petroleum Industry Guidance Note, Marine Oil Pollution: Response and Consultation Arrangements 2020.

5.2 Relevant Persons Consultation Objectives

TGS has identified a set of key objectives for the relevant persons consultation programme. These objectives were developed with the intention to inform and build capacity in relevant persons, to the extent that they understand the potential risks and impacts associated with the proposed Otway Basin 3D MC MSS on their specific functions, activities and interests, and to make available the opportunity to raise any concerns, objections or claims they may have. In addition, this consultation will ensure TGS understands the concerns each relevant person may have and hear suggestions on how these concerns can be mitigated through appropriate controls in the EP. Finally, to ensure that wherever practicable concerns raised are incorporated into the management of the proposed Otway Basin 3D MC MSS as a component of this EP.

The key objectives for the relevant persons consultation programme included:

- Undertake the consultation process in accordance with the key principles of effective consultation (Section 7 Guidance Document);
- Identify all relevant persons in accordance with the Guidance Document, supplementary documents and the Appeal Decision;
- Initiate and ensure ongoing transparent, open and honest communication with all relevant persons;
- Provide relevant persons with sufficient information to allow them to make an informed assessment of the possible consequences of the activity on their functions, activities, values or sensitivities;
- Provide adequate opportunity (i.e. reasonable period) for relevant persons to consider and query the information and provide feedback;
- Provide a mechanism for assessing the merit of any objections or claims received;
- Where applicable, demonstrate where control measures have been incorporated as a result of relevant persons consultation feedback;
- Support ongoing relevant persons identification and consultation throughout the project; and
- Demonstrate to NOPSEMA that completed and continuing consultation with relevant persons is consistent with the requirements of the Environmental Regulations.

5.3 Requirements for Identification of Relevant Persons

Regulation 11A of the Environment Regulations holds that the titleholder (in this case TGS) must consult each of the following (a 'relevant person'):

(a) Each Department or agency of the Commonwealth to which the activities to be carried out under the environment plan, or the revision of the environment plan, may be relevant;

(b) Each Department or agency of a State or the Northern Territory to which the activities to be carried out under the environment plan, or the revision of the environment plan, may be relevant;

(c) The Department of the responsible State Minister, or the responsible Northern Territory Minister;

(d) A person or organisation whose functions, interests or activities may be affected by the activities to be carried out under the environment plan, or the revision of the environment plan; and

(e) Any other person or organisation that the titleholder considers relevant.

On 21 September 2022, Justice Bromberg handed down his judgement in the Primary Decision. One of the issues covered in the judgement was how titleholders should identify the *"universe of relevant persons"* that may fall within section 11A(1) of the Environment Regulations. The process of identifying relevant person(s) is the first step in fulfilling the requirements of section 11A of the Environment Regulations.

As stated by Justice Bromberg in the Primary Decision, determining who falls within the description of (a), (b), (c) and (e) is a "*relatively straightforward exercise*" (para. 136 of the Primary Decision). However, the description of a relevant person in (d) can raise "*substantial complexity*" (para. 137 of the Primary Decision) as:

- The number of persons falling within the description may be very large and in numerous categories;
- The words "*functions, interests or activities*" must be construed with their intended meaning; and
- The nature and extent of any potential effect upon the "*functions, interests or activities*" or particular persons or the categories of particular persons may be difficult to assess.

Further to the above, the Appeal Decision (and subsequently the Guidance Document) provides guidance on the phrase "*functions, interests or activities*". Based on these two documents, the phrase "*functions, interests or activities*" should be constructed broadly as it best promotes the objects of the Environment Regulations, including that activities are carried out in a manner consistent with the principles of ESD. The phrase is a composite one, each part of which has work to do in identifying relevant persons. The meaning of each part of the phrase is defined in the Guidance Document as follows:

- Functions – refers to "*a power or duty to do something*" (para. 60 of the Appeal Decision);
- Interests – to be construed as conforming with the accepted concept of "*interest*" in other areas of public administrative law. Includes "*any interests possessed by an individual whether or not the interest amounts to a legal right or is a proprietary or financial interest or relates to reputation*" (para. 63 & 65 of the Appeal Decisions); and
- Activities – to be read broadly and is broader than the definition of 'activity' in regulation 4 of the Environment Regulations and is likely directed to what the relevant person is already doing (para. 51, 58 and 59 of the Appeal Decision).

A methodology has been developed to accurately and transparently determine the relevant person(s) associated with the Otway Basin 3D MC MSS, including those whose functions, interests, or activities as per (d) may be affected by the activities proposed. This methodology also includes an identification of those relevant person(s) that fall under (a), (b), (c) and (e) of 11A(1) above.

For the purpose of this EP, and in accordance with the Guidance Document (Section 6), the process of identifying relevant persons under Section 11A(1)d) has encompassed the concept of 'Decisional Choice' of which individuals/organisations may have functions, interests or activities in the activities proposed to be undertaken as part of this EP.

5.4 Method for Identification of Relevant Persons

In accordance with the Guidance Document, this section sets out the process by which relevant persons were identified through initial consultation and will continue to be identified through continuing consultation throughout the duration of the Otway Basin 3D MC MSS. The process followed by TGS is outlined below:

1. Scope out the proposed activity to ensure it is properly understood by the titleholder;
2. Determine the potential impacts and risks associated with the activity;

3. Determine the extent of the EMBA by the activity;
4. Characterise the environment within the EMBA by developing a broad understanding of the values and sensitivities in the EMBA; and
5. Identify relevant persons by determining potential functions, interests or activities of persons that may intersect with the OA or EMBA. As part of this process, each relevant person(s) will be assessed on a case-by-case basis to enable appropriate consultation based on their potential functions, interests, or activities within the EMBA.

Each of these four steps in TGS's methodology for identifying relevant persons are discussed in further detail in the following sections. This process ensures that relevant persons are identified not only in terms of the spatial boundary of the OA or EMBA but were also identified in regard to their functions, interests or activities bound by the values and sensitivities of the EMBA.

The consultation undertaken with these relevant persons is outlined further in **Section 5.5**.

5.4.1 Scope the Activity

The first important step of any consultation methodology is to ensure that the proposed activity is properly understood by the titleholder, including the potential impacts and risks associated with that activity to enable identification of relevant person(s). This involves TGS determining the scope and extent of the phase or stage of activity, including any associated activities, proposed to be commenced.

A detailed description of the proposed Otway Basin 3D MC MSS is included within **Section 3**, and outlines the Otway Basin 3D MC MSS location, the timing and duration of the Otway Basin 3D MC MSS and the specifications of the Seismic Survey including source configuration, streamer configuration, sail lines and the project related vessels.

5.4.2 Determine the Impacts and Risks

A detailed discussion on the potential impacts and risks associated with the activity is included within **Section 6.1** of this EP, which resulted in the identification of the following activities which may result in impacts or risks to the functions, interests or activities of potentially relevant person(s):

- Planned activities:
  - Physical presence of the Seismic Vessel and towed equipment (**Section 7.1**);
  - Acoustic disturbance to the marine environment (**Section 7.2**);
  - Routine permissible waste discharges (**Section 7.3**);
  - Atmospheric emissions (**Section 7.4**); and
  - Artificial light emissions (**Section 7.5**).
- Unplanned activities:
  - Establishment of invasive marine species (**Section 8.1**);
  - Streamer loss (**Section 8.2**);
  - Vessel collision or sinking, and potential fuel spill from ruptured fuel tanks, if any (**Section 8.3**);
  - Hydrocarbon spill response (**Section 8.4**); and

- Accidental release of hazardous and non-hazardous materials (**Section 8.5**).

5.4.3 Determine the Extent of the EMBA

To identify potentially relevant person(s), the environment that may be affected (**EMBA**) needs to be defined in order to determine the potential exposure for those relevant person(s). As discussed within **Section 4.1**, most activities (either planned or unplanned) associated with the Otway Basin 3D MC MSS may affect the environment up to a few kilometres from the source location which is constantly moving through the Acquisition Area. A significant unplanned event, such as a vessel fuel oil spill, has the potential to impact the existing environment over a substantially larger area than that affected by planned activities, and minor unplanned events. Therefore, an EMBA was derived using stochastic fuel oil dispersion and fate modelling. This modelling simulated the occurrence of 100 realistic spill events of 1,066 m^3 of MDO from five locations within the OA, randomly distributed over the previous decade. An output of this modelling was the maximum extent at which various environmental thresholds were reached, including for floating, entrained, dissolved and shoreline accumulations of hydrocarbons.

The extent of the EMBA was based on a combination of the maximum extent of the fuel oil spill trajectory at which entrained hydrocarbons were above the low threshold from each of the five modelled release locations. Utilising the maximum extent from all five spill locations results in a worst-case scenario for the spatial extent of impacts from the Otway Basin 3D MC MSS.

As displayed in **Figure 7** of **Section 4.1**, the EMBA extends beyond the OA into coastal areas from the eastern extent of South Australia, along most of the Victorian coastline and Bass Strait to the southern part of New South Wales, and extends south from the northwestern coastline of Tasmania and down and beyond the west and southern coastline of Tasmania.

5.4.4 Characterise the Environment within the OA and EMBA

The EMBA is an important tool to assist TGS with determining the extent to which the values and sensitivities need to be considered in relation to the Otway Basin 3D MC MSS. Once the environment within this EMBA has been characterised, it is then possible to determine the person(s) which fall within (a) to (e), listed in **Section 5.4.1** above, that may be impacted.

Section 4 provides a detailed characterisation of the values and sensitivities of the environment within the EMBA, including details on the physical environment, marine protected areas and sensitive areas, the biological environment, cultural and heritage values, and the socio-economic environment. The values and sensitivities associated with the EMBA have been guided by various databases and search tools, including the Protected Matters Search Tool from the DoCCEEW, the National Native Title Register search tool, the Australasian Underwater Cultural Heritage database, the National Electronic Approvals Tracking System and commercial fisheries data using the CAES blocks. From this guidance, further details on specific values and sensitivities have been established from published literature, bioregional planning documents, EPBC Act Conservation Management Plans, Recovery Plans and Conservation Advice, organisation strategic plans and annual reports, along with details provided by relevant persons where provided. Utilising this detailed information, it is then possible to accurately determine the functions, interests or activities that relevant persons may have with any aspect of the existing environment.

5.4.5 Identification of Relevant Persons for Informing Consultation Effort

As stated in Section 7 of the Guidance Document, the consultation process should be appropriate for the category of relevant person, and the type of function, interest, or activity; where interests are held communally, the method of consultation will need reasonably to reflect the characteristics of the interests affected by the proposed activity.

The identification of relevant person(s) is a key step in the preparation of an EP due to the requirement of regulation 11A in that a titleholder must consult with each relevant person. Regulation 11A(2) and (3) requires the titleholder to give each relevant person sufficient information to allow the relevant person to make an informed assessment of the possible consequences of the activity on the functions, interests or activities of the relevant person and allow the relevant person a reasonable period for the consultation.

It is considered that not all relevant persons require the same amount of information or period for consultation based on the various different functions, interests or activities of the relevant person and the manner in which they may be impacted by the Otway Basin 3D MC MSS. As such, a system has been developed as outlined in **Section 5.4.5.1** as a starting point for consulting with relevant persons. Where relevant persons identified the need for additional information or additional time to adequately assess the potential impacts from the Otway Basin 3D MC MSS on their functions, interests, or activities then this was worked through with them on a case-by-case basis to ensure a bespoke consultation process was followed where required.

5.4.5.1 Consultation effort

As outlined above, relevant persons have different functions, interests or activities associated with the EMBA and as such, warrant different levels of effort of consultation. The methods recognise the process is iterative, and not a 'one-size-fits-all' method can be applied across all relevant persons, or potentially relevant persons. It needs to recognise efforts/methods across individual relevant persons is guided by the amount and format of the information to be exchanged, if sufficient information has been provided, and the differences in timeframes required, to ensure relevant persons have sufficient timeframes to respond (**Section 5.4.5**). Effort is therefore guided by the factors unique for each relevant persons, as determined by their area across which their functions, interests or activities overlap with sensitivities in the EMBA or OA (noting that the OA and EMBA areas are defined terms in this EP).

Where a relevant person has requested bespoke consultation requirements, TGS has sought to accommodate those requirements to ensure that the relevant person is able to receive sufficient information and to have a reasonable opportunity to be consulted. For example, in some cases, TGS was not willing to proceed with in-person consultation events because there has been inaccurate and misleading information shared by those groups within online media. TGS made an assessment that for those groups, online consultation sessions will better enable the relevant persons to receive accurate information and ask questions about the proposal. This has enabled TGS to reasonably share the accurate information about the proposal and ensure interest-based concerns can be raised and receive a reasonable response. Another bespoke requirement that TGS has accommodated is in relation to level of engagement. For example, where a relevant person has initially indicated a low effort of consultation may be sufficient, if that relevant person subsequently indicated they require further or continuing consultation, this is accommodated into the consultation framework as required.

5.4.5.2 Relevant Person Identification

5.4.5.2.1 Relevant Person Identification under Regulation 11A(1)(a), (b), (c) and (e)

As stated by Justice Bromberg in the Primary Decision, determining who falls within the description of regulation 11A(1)(a), (b), (c) and (e) is a relatively straightforward exercise. Due to the prescribed nature of the requirements of regulation 11A(1)(a), (b), (c) and (e) the methods for identifying relevant persons under these parts relies on industry and expert knowledge and experience (including previous work history) and the use of other EPs associated with seismic surveys which have similar risks and impacts as the proposed Otway Basin 3D MC MSS. In addition to this, searches of publicly available information, including, but not limited to, government databases and registers, web searches for background information on functions, interests or activities were conducted.

Based on the above, TGS has utilised previous operational experience in Australia and expert knowledge of the impacts and risks of the Otway Basin 3D MC MSS, along with assessing recently approved EPs for seismic surveys to identify a list of relevant persons under regulation 11A(1)(a), (b), (c) and (e). **Table 38** provides an outline of those person(s) who are considered relevant under (a), (b), (c) and (e) along with a justification as to why they are considered relevant under the Environment Regulations.

It is noted that only those relevant persons confirmed as relevant for the purpose of this EP are listed in **Table 38**. All records of potentially relevant persons communicated with by TGS are listed in **Appendix H**, where the potentially relevant person has confirmed they are not considered as relevant for the purpose of this EP, a record of this is indicated.

Table 38 Regulation 11A(1)(a), (b), (c) and (e) Relevant Person Identification

Relevant Person	Justification
Regulation 11A(1)(a): Each Department or agency of the Commonwealth to which the activities to be carried out under the environment plan, or the revision of the environment plan, may be relevant	
Australian Communications and Media Authority (**ACMA**)	The ACMA is the statutory body responsible for regulating communications and media services in Australia, including the submarine cable regime. A previous EP found ACMA to be included as a relevant person for the proposed survey (on the basis information received by a third-party relevant persons), as there may be submarine cable systems managed by ACMA in the vicinity of the Otway Basin 3D MC MSS.
Australian Fisheries Management Authority (**AFMA**)	The AFMA is the Australian Government agency responsible for the management and sustainable use of fisheries resources including combating illegal fishing activities in the Australian Fishing Zone that covers 8,148,250 square kilometres, the third largest in the world and in most of Australia's EEZ, which extends to 200 nautical miles (370 km) from the coastline of Australia and its external territories, except where a maritime delimitation agreement exists with a state. AFMA is an agency of the Australian Department of Agriculture, Fisheries and Forestry (formerly the Department of and Water Resources). AFMA is responsible for the efficient management and sustainable use of Commonwealth fish resources. As the Otway Basin 3D MC MSS has the potential to impact Commonwealth managed fisheries, the AMFA is considered relevant, including those specific fisheries that operate in the Southern waters of the GAB, Bass Strait and Tasman Sea. Specific details of commonwealth managed fisheries under Australian Fisheries Management Authority is included within the assessment under 11A(1)(d), contained within **Table 28**.
Australian Hydrographic Office (**AHO**)	The AHO is responsible for the publication and distribution of nautical products and other information required for the safety of ships navigating in Australian waters. The Otway Basin 3D MC MSS will pose a potential risk to the safety of other ships navigating in the area, therefore the AHO is considered to be a relevant person. In addition, the Otway Basin 3D MC MSS is required to be notified to the AHO by TGS a minimum of three weeks prior to the commencement of activities.

Relevant Person	Justification
Australian Maritime Safety Authority (**AMSA**)	The AMSA is Australia's national regulatory body promoting the safety and protection of the marine environment and combating ship-sourced pollution and provides for the infrastructure and safety of navigation in Australian waters. Based on this, it is considered AMSA is a relevant person under regulation 11A(1)(a).
Department of Agriculture, Fisheries and Forestry (**DAFF**)	The DAFF operates across a range of regulations across agriculture, forestry, and fisheries. Relevant to this EP, the DAFF enforces laws related to biosecurity controls of pest and disease risks of vessels arriving in Australia and as such are considered a relevant person. It is worth noting that the DAFF was, up until 30 June 2022, the Department of Agriculture, Water and the Environment with which TGS also consulted.
Department of Climate Change, Energy, the Environment and Water (**DCCEEW**)	The DCCEEW protects Australia's natural environment and heritage sites, helps respond to climate change and carefully manages water and energy resources. The DCCEEW is considered a relevant person due to the overarching directive in managing the natural environment and due to the potential impacts and risks associated with the Otway Basin 3D MC MSS, particularly with reference to Marine Parks and feedback from the Director of National Parks. Parks Australia and the Director of National Parks (**DNP**) are responsible for the six national parks, 60 marine parks and the Australian National Botanic Gardens. The OA associated with the Otway Basin 3D MC MSS overlaps with two AMPs, with the EMBA overlapping with a further eight AMPs, and as such the requirements for managing potential risks and impacts on those AMPs from the Otway Basin 3D MC MSS results in Parks Australia and the DNP being considered relevant persons. It is worth noting that the DCCEEW was, up until 30 June 2022, the Department of Agriculture, Water and the Environment with which TGS also consulted (see **Appendix G**).
Department of Defence (**DoD**)	The DoD manages Royal Australian Navy training activities at sea. Their Maritime Activities Environmental Management Plan recognises that some key training areas are locations where a number of differing activities may be conducted simultaneously, accordingly, separate Planning Handbooks have been developed for these areas to assist exercise planners in considering the environmental implications of various activities in their area. Peacetime activities include maritime surveillance and response within Australia's offshore maritime zones, hydrographic, oceanographic and meteorological support operations. Bases are established in Hobart, Tasmania and Cerebus, Melbourne. Defence activities have been identified in the OA (historic UXO dump sites) and in the wider EMBA and as such the DoD are considered relevant persons and has been consulted with.
Fisheries Research and Development Corporation (**FRDC**)	The FRDC promotes planning and investment in fisheries research and development (**R&D**) to support the sustainability of aquatic sectors and aquatic ecosystems. It is a statutory corporation under the Primary Industries Research and Development Act 1989 and is responsible to the Minister for Agriculture, Fisheries and Forestry. Its stakeholders include indigenous, commercial and recreational fishing and aquaculture. As such, the FRDC are considered relevant persons and as such has been consulted with.
Geoscience Australia (**GA**)	GA is an agency of the Australian Government that carries out geoscientific research and is the government's technical adviser on all aspects of geoscience, and custodian of the geographic and geological data and knowledge of the nation. GA is considered a relevant person due to their experience with and research into marine seismic surveying.
National Native Title Tribunal (**NNTT**)	The NNTT is an independent body established under the Native Title Act 1993 in Australia as a special measure for the advancement and protection of Aboriginal and Torres Strait Islander peoples. One of its functions is to assist people in negotiations about proposed developments, and to arbitrate in some situations where the people cannot reach agreement about proposed developments. As such, the NNTT are considered relevant persons and as such has been consulted with.

Relevant Person	Justification
National Offshore Petroleum Titles Administrator (**NOPTA**)	NOPTA administers titles and data management for petroleum and greenhouse gas titles in Australian Commonwealth waters in support of the effective regulation and management of offshore petroleum resources consistent with good oil field practice and optimum recovery. Seismic surveys are an integral aspect of developing Australia's offshore petroleum resources. Due to their administrative role in offshore petroleum resources, NOPTA is considered a relevant person, and as such has been consulted with.
Regulation 11A(1)(b): Each Department or agency of a State to which the activities to be carried out under the environment plan, or the revision of the environment plan, may be relevant	
Victoria Departments or Agencies	
Coastcare Victoria	Coastcare Victoria is a collection of community groups and volunteers who have an interest in the protection and management of Victoria's 2000 km of coastline. Coastcare Victoria have interests in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, Coastcare Victoria are considered relevant persons and have been consulted with.
Colac Otway Shire Council	The Colac Otway Shire Council is a local government area located in Victoria's south-west coast. The shire covers an area of 3,438 km^2 and had a population of 22,177 in 2022. The Colac Otway Shire Council has interests within their shire's coastal and marine areas which overlap the EMBA. As such, the Colac Otway Shire Council is considered a relevant person and has been consulted with.
Commissioner for Environmental Sustainability of Victoria (Department of Energy, Environment and Climate Action)	The Commissioner for Environmental Sustainability for Victoria provides independent scientific reporting to inform policymakers, scientists, and the wider Victorian community on the state's natural environment and supports ecological sustainable development. The Commissioner is an independent statutory role and is a Governor in Council appointment who prepares statutory reports according to the Commissioner for Environmental Sustainability Act 2003. The Commissioner for Environmental Sustainability of Victoria was suggested by another relevant person as potentially having interests in the Otway Basin 3D MC MSS. As such, the Commissioner for Environmental Sustainability of Victoria is considered a relevant person and have been consulted with.
Corangamite Shire Council	The Corangamite Shire Council is a local government area located in Victoria's southwest region. The shire covers an area of 4,408 km^{2}and had a population of 16,140 in June 2018. The Corangamite Shire Council has interests within their shire's coastal and marine areas which overlap with the EMBA. As such, the Corangamite Shire Council is considered a relevant person and has been consulted with.
Department of Energy, Environment and Climate Action	The Department of Energy, Environment and Climate Action is responsible for various matters related to the environment, including the coastal environment, energy, and climate change. The department was renamed from the Department of Environment, Land, Water and Planning on 1 January 2023. As such, the Department of Energy, Environment and Climate Action are considered relevant persons and have been consulted with.
Department of Transport and Planning (VIC)	The Department of Transport and Planning (formerly known as the Department of Transport) is responsible for planning and operating transport across Victoria, including maritime affairs within Victoria. The Department of Transport and Planning has interests within the Victorian waters that overlap the EMBA. As such, the Department of Transport and Planning is considered a relevant person and has been consulted with.
East Gippsland Shire Council	The East Gippsland Shire Council is a local government area located in Victoria's eastern region. The shire covers an area of 20,940 km^{2}and had a population of 46,818 in June 2018. The East Gippsland Shire Council has interests within the shire's coastal and marine areas which overlap with the EMBA. As such, the East Gippsland Shire Council is considered a relevant person and has been consulted with.

Relevant Person	Justification
Environmental Protection Authority (**EPA**) - Victoria	The Environment Protection Authority Victoria is Victoria's environmental regulator. It is an independent statutory authority, established in 1971 under the Environment Protection Act 1970. The Environmental Protection Authority Victoria has interests in the Victorian coastal and marine area which overlaps with the EMBA. As such, the Environmental Protection Authority Victoria are considered relevant persons and have been consulted with.
Glenelg Shire Council	The Glenelg Shire Council is a local government area located in Victoria's southwest region. The shire covers an area of 6,219 km^2 and had a population of 19,665 in June 2018. The Glenelg Shire Council has interests within the shire's coastal and marine areas which overlap with the EMBA. As such, the Glenelg Shire Council is considered a relevant person and has been consulted with.
Mornington Peninsula Shire Council	The Mornington Peninsula Shire Council is a local government area in southeastern Metropolitan Melbourne. It is located south of the Melbourne City Centre and has an area of 724 km^2 and in June 2018 it had a population of 165,822. The Mornington Peninsula Shire Council have interests within the shire's coastal and marine areas which overlap with the EMBA. As such, the Mornington Peninsula Shire Council is considered a relevant person and has been consulted with.
Moyne Shire Council	The Moyne Council is a local government area in the Barwon southwest region of Victoria, located in the south-western part of the state. It covers an area of 5,481 km^2 (and in June 2018 had a population of 16,887. Moyne Shure Council has interests within the shire's coastal and marine areas which overlap with the EMBA. As such, the Moyne Shire Council is considered a relevant person and has been consulted with.
Parks Victoria	Parks Victoria is a government agency that was established in December 1996 as a statutory authority, reporting to the Victorian Minister for Environment and Climate Change. Its role is to protect and preserve Victoria state's natural and cultural heritage. Parks Victoria has interests in the coastal and marine areas that overlap with the EMBA. As such, Parks Victoria is considered a relevant person and has been consulted with.
South Gippsland Shire Council	The Shire of South Gippsland is a local government area located in the south-eastern part of the state. It covers an area of 3,296 km^2 and, in June 2018, had a population of 29,576. The South Gippsland Shire Council has interests within the shire's coastal and marine area which overlaps with the EMBA. As such, the South Gippsland Shire Council is considered a relevant person and has been consulted with.
Surf Coast Shire Council	The Surf Coast Shire is a local government area in the Barwon south west region of Victoria, , located in the south-western part of the state. It covers an area of 1,553 km^2 and in June 2018 had a population of 32,251. Surf Coast Shire Council has interests within the shire's coastal and marine areas which overlap with the EMBA. As such, the Surf Coast Shire Council is considered a relevant person and has been consulted with.
Victorian Fisheries Authority (**VFA**)	The VFA is an independent statutory authority established to effectively manage VIC's fisheries resources, to benefit recreational, commercial, aquaculture and aboriginal interests. They carry out research across VIC to monitor fish stocks and fish habitat. Branches include the Fisheries Management and Science Branch, the Ocean General Fishery Manager and Rock Lobster and Giant Crab Fishery Manager. Various commercial fisheries that fall under the management of the VFA overlap with the OA and EMBA for the Otway Basin 3D MC MSS and as such the VFA are considered relevant persons and have been consulted with.
Warrnambool City Council	The City of Warrnambool is a local government area in the Barwon south-west region of Victoria located in the south-western part of the state. It covers an area of 121 $km^2$and in June 2018 had a population of 34,862. It is entirely surrounded by the Shire of Moyne and the Southern Ocean. The Warrnambool City Council has interests within the shire's coastal and marine areas which overlap with the EMBA. As such, the Warrnambool City Council is considered a relevant person and has been consulted with.

Relevant Person	Justification
Wellington Shire Council	The Shire of Wellington is a local government area located in the eastern part of the state. It covers an area of 10,817 km^2 and in June 2018 had a population of 44,019. The Wellington Shire Council has interests within the shire's coastal and marine areas which overlap with the EMBA. As such, the Wellington Shire Council is considered a relevant person and has been consulted with.
South Australia Departments or Agencies	
Department of Energy and Mining (South Australia)	The Department for Energy and Mining is responsible for delivering reliable and secure energy supplies from South Australia's mineral and energy resources. Department of Energy and Mining (South Australia) has interests in the wider. As such, the Department of Energy and Mining (South Australia) is considered a relevant person and has been consulted with.
Department of Environment and Water (South Australia)	The Department for Environment and Water is responsible for ensuring that South Australia's natural resources are managed productively and sustainably, while improving the condition and resilience of the state's natural environment. The Department of Environment and Water (South Australia) has interests in the wider EMBA. As such, the Department of Environment and Water (South Australia) is considered a relevant person and has been consulted with.
Department of Infrastructure and Transport	The Department of Infrastructure and Transport delivers infrastructure and transport services to all South Australians. The department consists of multiple teams including The Marine Safety South Australia is an agency within the. Marine Safety South Australia
Department of Primary Industries and Regions (**PIRSA**)	The PIRSA, is an agency of the South Australian Government whose focus is the economic development of the state of South Australia. Its key areas of work include primary sector industries, including marine aquaculture and biosecurity. The Fisheries and Aquaculture division manages the state's fish stocks, along with industry and the community, by developing and implementing policy and regulations to ensure sustainable development of the aquaculture industry. It employs Fisheries Officers to monitor compliance with fishing regulations. The South Australian Research and Development Institute (**SARDI**) is the State Government's principal research institute, and forms part of PIRSA. Various commercial fisheries that fall under the management of the PIRSA overlap with the OA and EMBA for the Otway Basin 3D MC MSS and as such the PIRSA is considered a relevant person and has been consulted with.
District Council of Grant	The District Council of Grant is a local government area located in the Limestone Coast region of South Australia and is the southernmost council in the state. It has an area of 1,904 km^2 and a population of 8,203 as of 2016. The District Council of Grant have interests in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the District Council of Grant are considered relevant persons and have been consulted with.
EPA - South Australia	The EPA is South Australia's independent environment protection regulator. It provides advice to the Minister for Environment through reports, and releases statements to the public detailing significant environmental matters. Its role also includes formulation of environmental protection policies. The EPA South Australia have interests in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the EPA South Australia are considered relevant persons and have been consulted with.
National Parks and Wildlife Services South Australia - Marine Parks	South Australia has 19 marine parks which are overseen by the National Parks and Wildlife Services South Australia. It administers marine parks management plans and zoning arrangements including details around fishing restrictions. The National Parks and Wildlife Services South Australia have interests in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, National Parks and Wildlife Services South Australia are considered relevant persons and have been consulted with.

Relevant Person	Justification
Wattle Range Council	Wattle Range Council is a local government area in the Limestone Coast region of South Australia. It stretches from the coast at Beachport east to the VIC border covering an area of 3,924km^2. It had a population of over 11,677 as at the 2016 census. The District Council of Wattle Range have interests in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the District Council of Wattle Range are considered relevant persons and have been consulted with.
Tasmania Departments or Agencies	
Aboriginal Heritage of Tasmania (Part of the Department Premier and Cabinet)	Aboriginal Heritage Tasmania aims to protect and promote TAS' unique Aboriginal heritage and facilitate the return of land to TAS' Aboriginal people. It oversees the implementation of the Aboriginal cultural management outcomes of the Tasmanian Wilderness World Heritage Area Management Plan 2016. The Aboriginal Heritage of Tasmania have interests in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Aboriginal Heritage of Tasmania are considered relevant persons and have been consulted with.
Circular Head Council	Circular Head Council is a local government body in TAS covering the far north-west of TAS. It is classified as a rural local government area with a population of 8,066, as of 2018 and covers an area of 4,898 km^2. The Circular Head Council have interests in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Circular Head Council are considered relevant persons and have been consulted with.
Department of Natural Resources and Environment	The TAS Department of Natural Resources and Environment is the government department of the Tasmanian Government responsible for supporting primary industry development, the protection of Tasmania's natural environment, effective land and water management and the protection of TAS' relative disease and pest free status. The Department of Natural Resources and Environment (TAS) have interests in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Department of Natural Resources and Environment (TAS) are considered relevant persons and have been consulted with.
Department of State Growth – Mineral Resources	The purpose of the Department of State Growth – Mineral Resources, is to give effect to government policy in relation to minerals and petroleum resources. It produces and promotes up-to-date geoscientific information on TAS as an aid to the mineral and petroleum exploration industries, other government agencies and the general public, in order to improve the State's economic position, and to promote sustainable land-use planning and environmental management. The Department of State Growth have interests in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Department of State Growth are considered relevant persons and have been consulted with.
Environmental Protection Authority - Tasmania	The EPA's purpose is to regulate developments and activities that may impact on environmental quality and to promote best practice and sustainable environmental management. It is an independent statutory authority under the Environmental Management and Pollution Control Act 1994. The EPA Tasmania have interests in the wider EMBA which may be impacted in the unlikely event of a fuel spill. EPA Tasmania is identified as the Control Agency for any oil spill that may enter coastal waters of TAS. It is the owner of the 'Tasmanian Marine Oil and Chemical Spill Contingency Plan (TasPlan). As such, the EPA Tasmania are considered relevant persons and have been consulted with.
Flinders Council	Flinders Council is a local government body in TAS, encompassing the Furneaux Group and nearby islands of Bass Strait, in the north-east of TAS. Flinders is classified as a rural local government area and has a population of 987, as of 2018. It covers a total area of 1,997 km^2. The Flinders Council have interests in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Flinders Council are considered relevant persons and have been consulted with.

Relevant Person	Justification
King Island Shire Council	King Island Council is a local government body in TAS, encompassing King Island and the adjacent minor islands within Bass Strait, in the north-west of TAS. The King Island local government area is classified as rural and has a population of 1,601, as of 2018. The islands cover an area of 1,096 km^2. The King Island Council have interests in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the King Island Council are considered relevant persons and have been consulted with.
Marine and Safety Tasmania	Marine and Safety Tasmania is a statutory authority that was established on 30 July 1997 to ensure the safe operation of vessels, provide and manage marine facilities and manage environmental issues relating to vessels. Marine and Safety Tasmania have interests in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, Marine and Safety Tasmania are considered relevant persons and have been consulted with.
Tasman Council	Tasman Council is a local government body situated in the south-east of TAS. It is classified as a rural local government area and has a population of 2,404 as of 2018 and covers an area of 660 km^2. The Tasman Council have interests in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Tasman Council are considered relevant persons and have been consulted with.
New South Wales Departments or Agencies	
Department of Mining, Exploration and Geoscience	Mining, Exploration and Geoscience is a group within the Department of Regional NSW. Its role is to provide certainty to the mining industry and to local communities about the future of mining in NSW and to support industry to understand and fulfil its regulatory obligations. The Department of Mining, Exploration and Geoscience have interests in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Department of Mining, Exploration and Geoscience are considered relevant persons and have been consulted with.
Department of Planning and Environment	The New South Wales Department of Planning and Environment is a department of the NSW Government, responsible for planning. It is home to business units including the Environment and Heritage, Water, National Parks and Wildlife Services, and is responsible for the NSW Government's coastal management framework. The Department of Planning and Environment have interests in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Department of Planning are considered relevant persons and have been consulted with.
Department of Primary Industries (Marine Environment/Marine Parks)	The New South Wales Department of Primary Industries is an agency of the New South Wales Government, responsible for the administration and development for agriculture, fisheries, aquaculture, forestry, and biosecurity in NSW. The Department of Primary Industries have interests in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Department of Primary Industries are considered relevant persons and have been consulted with.
Gulaga and Biamanga Joint Authority	Located on the far south coast of NSW, Biamanga and Gulaga National Parks contain places sacred to the Yuin people, such as Mumbulla Mountain and Gulaga Mountain. The parks are jointly managed by the Aboriginal owners and the NSW National Parks and Wildlife Service, part of the Office of Environment and Heritage. The two boards of management have a majority of Aboriginal owners along with community and NPWS representation. The Gulaga and Biamanga Joint Authority have interests in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Gulaga and Biamanga Joint Authority are considered relevant persons and have been consulted with.

Relevant Person	Justification
New South Wales National Parks and Wildlife Service (**NSW NPWS**)	NSW NPWS manages protected areas which play a critical role in protecting biodiversity, as well as natural and cultural heritage in parks. NPWS create management documents for the purpose of protection, preservation and regeneration of parks and their values including the safeguard human life and property, protection of Aboriginal sites and assets and the promotion of conservation and biodiversity within the parks. The NSW NPWS have interests in the various environmental receptors the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the NSW NPWS are considered relevant persons and have been consulted with.
Transport for NSW	Transport for NSW manages roads and waterways to deliver safe and efficient transport systems in NSW. This includes commercial boating in the marine and coastal environments. Transport for NSW have interests in the wider EMBA which may be impacted in the unlikely event of a fuel spill. Transport for NSW is identified as the Control Agency for any oil spill that may enter coastal waters of NSW. It is the owner of the 'NSW State Waters marine oil and chemical spill contingency plan' As such, Transport NSW are considered relevant persons and have been consulted with.
Regulation 11A(1)(c): The Department of the responsible State Minister, or the responsible Northern Territory Minister	
Not applicable as the Otway Basin 3D MC MSS is not within State waters.	
Regulation 11A(1)(e): Any other person or organisation that the titleholder considers relevant	
None identified to date	

5.4.5.2.2 Relevant Person Identification under Regulation 11A(1)(d)

As stated by Justice Bromberg in the Primary Decision, the description of a relevant person given by (d) can raise substantial complexity. To address this complexity, this identification process has relied on the comprehensive identification of values and sensitivities within the EMBA (**Section 4**) and conducting an evaluation to discover possible intersections with the functions, interests and activities of people or organisations. In accordance with Section 6 of the Guidance Document, TGS has used a range of "*processes for identification of relevant persons*" that provides for "*sufficiently broad capture of ascertainable persons and organisations who may have their functions, interests or activities affected or that may be affected by the activity*".

TGS adopted the following processes when identifying relevant persons, which are consistent with the expectations set out in the Guidance Document. These are considered appropriate for the purpose of identifying the universe of relevant persons whose functions, interests or activities are associated with the environmental values and sensitivities in the EMBA:

- Publication in appropriate media formats to facilitate the process of self-identification of relevant person(s) (discussed further below);
- Searches of publicly available information, including, but not limited to, government databases and registers, web searches for background information on functions, interests or activities;
- Industry and expert knowledge and experience (including previous work history, professional networks);
- The use of other EPs associated with seismic surveys which have similar risks and impacts as the proposed Seismic Survey; and
- Utilisation of advice from relevant persons who may know of other persons or organisations that may be considered relevant, including through discussions with organisations representing traditional owner groups and workshops with nearby traditional owner groups.

After developing a comprehensive list of relevant persons using the above processes, was undertaken to ascertain the starting point of consultation requirements.

As outlined above, the consultation programme has provided for self-identification of relevant person(s) through public notification processes. It is anticipated the publication of the EP on NOPSEMA's website, TGS' website, national, state-wide (multiple states) and regional newspapers will further identify relevant persons who can be considered as self-identified via the public notifications process (see **Section 5.6** for further details).

Following the self-identification of a relevant person through this publication process, TGS will assess the information provided by the potentially relevant person to determine whether their functions, interests and activities, are likely to overlap the OA or EMBA and confirm they are relevant. If this assessment shows the person(s) is considered relevant for the purpose of this EP or it remains unclear whether they are relevant, then consultation will continue with them to confirm relevancy and ascertain the potential impacts and risks to their function, interest or activity, and the development of control measures to address those impacts and risks.

Following the process outlined above, and applying the descriptions detailed in **Section 5.4.5.1**, **Table 39** lists the relevant persons described by regulation 11A(1)(d). The 'Justification' column of **Table 39** provides details on the functions, interests or activities of the relevant person and why they are considered relevant for the Otway Basin 3D MC MSS. **Table 39** provides an outline of those person(s) who are considered relevant under (d), along with a justification as to why they are considered relevant under the Environment Regulations. A full report on the consultation undertaken with the relevant persons is included within **Appendix H**, as per the requirements of Regulation 16(b).

Only those relevant persons confirmed as relevant for the purpose of this EP are listed in **Table** 39. All persons engaged with by TGS, including those no longer considered relevant are listed in **Appendix G**.

Table 39 Regulation 11A(1)(d) Relevant Person Identification

Relevant Person	Justification
Traditional Owner Groups	
Aboriginal Heritage Council Tasmania (Report to AHT) (TAS)	The statutory Aboriginal Heritage Council was established in 2017 under the Aboriginal Heritage Act 1975. It is an independent body who provides advice and recommendations to the Minister for Aboriginal Affairs, the Director of National Parks and Wildlife, land managers and owners and other stakeholders on the protection and management of Aboriginal heritage in TAS. All members of the Council are from the TAS Aboriginal community and have experience and knowledge of Aboriginal heritage management. The Aboriginal Heritage Council of Tasmania have interests in receptors that overlap the OA and the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Aboriginal Heritage Council of Tasmania are considered relevant persons and have been consulted with.
Aboriginal Land Council of Tasmania (TAS)	The Aboriginal Land Council of Tasmania is the statutory body, established by law to own returned land on behalf of TAS' Aboriginal Community. The Aboriginal Lands Act (1995) sets out the establishment, election, and purpose of the Aboriginal Land Council of TAS. The Land Council is governed by a board of eight Aboriginal people, elected in a TAS Electoral Commission election that is open to all people on the Aboriginal electors roll. The Council includes two representatives from each of the South, North and North West regions and one each from truwana/Cape Barren Island and Flinders Island. The Aboriginal Land Council of Tasmania have interests in receptors that overlap the OA and the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Aboriginal Land Council of Tasmania are considered relevant persons and have been consulted with.

Relevant Person	Justification
Aboriginal Launceston (TAS)	Aboriginal Launceston is a website run by two educators for teachers and anyone interested in TAS' Aboriginal past. The website was set up to help navigate the challenges and demands faced by teachers who are required to implement First Nations histories and cultures content in their programs. The website, through the two primary educators of the website, seek to provide information that is aligned to First Nations topics in the Australian Curriculum. Aboriginal Launceston has interests in receptors that overlap the OA and the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, Aboriginal Launceston are considered relevant persons and have been consulted with.
Bega Local Aboriginal Land Council (NSW)	The Bega Local Aboriginal Land Council is one of 120 similar organisations that comprise a network that covers the NSW landmass. The Bega LALC mandated area (~5900sq.km) is approximately 35 kilometres north south and 180 kms east to west. The Bega Local Aboriginal Land Council have interests in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Bega Local Aboriginal Land Council are considered relevant persons and have been consulted with.
Bodalla Local Aboriginal Land Council (NSW)	The Bodalla Local Aboriginal Land Council is one of 120 similar organisations that comprise a network that covers the NSW landmass. The Bodalla Land Aboriginal Land Council have interests in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Bodalla Land Aboriginal Land Council are considered relevant persons and have been consulted with.
Bunurong Land Council Aboriginal Corporation (VIC)	Bunurong Land Council Aboriginal Corporation are a Traditional Owner organisation that represent the Bunurong people of the South-Eastern Kulin Nation. It is the Registered Aboriginal Party for and on behalf of Bunurong People. The Bunurong Land Council Aboriginal Corporation have interests in receptors that overlap the OA and the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Bunurong Land Council Aboriginal Corporation are considered relevant persons and have been consulted with.
Burrandies Aboriginal Corporation (South Australia)	The Burrandies Aboriginal Corporation has been serving the Indigenous Community of the South East of South Australia since 1999. The Burrandies Aboriginal Corporation formally recognises the partnership between Burrandies and the South East Aboriginal Focus Group (traditional custodians of the South East of South Australia) and acknowledges that the Lartara-wirkeri cultural governance framework will guide how Burrandies Aboriginal Corporation undertakes all business, and especially any and all business undertaken with the South East Aboriginal Focus Group and on behalf of the South East Aboriginal Focus Group. The Burrandies Aboriginal Corporation have interests in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Burrandies Aboriginal Corporation are considered relevant persons and have been consulted with.
Cape Barren Island Aboriginal Association Incorporated (TAS)	Cape Barren Island Aboriginal Association Incorporated was established in 1972 and is overseen by an Aboriginal Management Committee. The Cape Barren Island Aboriginal Association Inc have interests in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Cape Barren Island Aboriginal Association Inc are considered relevant persons and have been consulted with.

It is governed by its members, Gunditjmara traditional owners and native title holders in line with the Corporations (Aboriginal and Torres Strait Islander) Act 2006. The Gunditj Mirring Traditional Owners Aboriginal Corporation have interests in receptors that overlap the OA and the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Gunditj Mirring Traditional Owners Aboriginal Corporation are considered relevant persons and have been consulted with.
Karadi Aboriginal Corporation (TAS)	Karadi Aboriginal Corporation is an inclusive Aboriginal Community Controlled Organisation founded in 1988. It provides leadership in the sector and serving Aboriginal people of Southern Tasmania. The Karadi Aboriginal Corporation have interests in receptors that overlap the OA and the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Karadi Aboriginal Corporation are considered relevant persons and have been consulted with.
Lia Pootah Aboriginal Corporation (TAS)	The Lia Pootah Aboriginal Corporation represent the Lia Pootah people of TAS. The Lia Pootah Aboriginal Corporation have interests in receptors that overlap the OA and the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Lia Pootah Aboriginal Corporation are considered relevant persons and have been consulted with.
melythina tiakana warrana Aboriginal Corporation (TAS)	melythina tiakana warrana Aboriginal Corporation is a registered Aboriginal organisation with the Office of the Registrar of Indigenous Corporations, under the Corporations (Aboriginal and Torres Strait Islander) Act 2006. melythina tiakana warrana members are direct descendants of the Aboriginal Ancestors from the Country of tebrakuna, known as the region of northeast TAS. The melythina tiakana warrana Aboriginal Corporation have interests in receptors that overlap the OA and the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the melythina tiakana warrana Aboriginal Corporation are considered relevant persons and have been consulted with.
Merrimans Local Aboriginal Land Council (NSW)	The Merrimans Local Aboriginal Land Council is one of 120 similar organisations that comprise a network that covers the NSW landmass. The Merrimans Local Aboriginal Land Council have interests in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Merrimans Local Aboriginal Land Council are considered relevant persons and have been consulted with.

Relevant Person	Justification
New South Wales Aboriginal Land Council (**NSWALC**)	The NSWALC was established in the 1970s to assist in the fight for land rights. It was formally constituted as a statutory corporation under the New South Wales Aboriginal Land Rights Act in 1983. It is the State's peak representative body in Aboriginal Affairs. It aims to protect the interests and further the aspirations of its members and the broader Aboriginal community. It is the largest member based Aboriginal organisation in NSW. There are 120 LALCs, each constituted over a specific area in NSW. Their boundaries may not align with cultural or traditional associations with Country. LALCs cannot provide certification of Aboriginality. They can, however, choose to confirm the membership of people accepted as adult Aboriginal people who are listed on their membership roll. The NSWALC have interests in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the NSWALC are considered relevant persons and have been consulted with.
Ngarrindjeri Aboriginal Corporation RNTBC (South Australia)	The Ngarrindjeri Aboriginal Corporation RNTBC acts as agent for the native title rights and interests of the Ngarrindjeri people. The determination area for Part A is located east of Adelaide, from Murray Bridge southwest to Cape Jervis and southeast almost to Tintinara. Part B of the determination is on-going. The Ngarrindjeri Aboriginal Corporation RNTBC have interests in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Ngarrindjeri Aboriginal Corporation RNTBC are considered relevant persons and have been consulted with.
Ngarrindjeri Ruwe Empowered Communities (South Australia)	The Ngarrindjeri Ruwe Empowered Communities works within the Ngarrindjeri Native Title region to work with the Aboriginal and Torres Strait Islander community to implement the Australian Government's Empowered Communities initiative to support the continual empowerment of Aboriginal communities by Aboriginal people. Empowered Communities is an Indigenous designed and led empowerment initiative. The Ngarrindjeri Ruwe Empowered Communities is a backbone organisation that provides the supporting infrastructure to coordinate work among Empowered Communities partner organisations, to progress the Regional Development Agenda and the overall implementation of the model across the region. The Ngarrindjeri Ruwe Empowered Communities have interests in receptors that overlap the OA and the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Ngarrindjeri Ruwe Empowered Communities are considered relevant persons and have been consulted with.
NTSCORP Limited (NSW)	NTSCORP Ltd is the Native Title Service provider for Aboriginal Traditional Owners in the New South Wales, promoting social justice, economic, cultural and social independence for Traditional Owners of the land, seas and waters. NTSCORP Ltd were suggested to TGS as a potentially relevant person during consultation with another relevant person because of their interest within NSW seas. As such NTSCORP Ltd is considered a relevant person and has been consulted with.
Parrdarrama Pungenna Aboriginal Corporation (TAS)	Parrdarrama Pungenna Aboriginal Corporation represents Aboriginal people in the east coast and TAS Peninsula. The Parrdarrama Pungenna Aboriginal Corporation have interests in receptors that overlap the OA and the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Parrdarrama Pungenna Aboriginal Corporation are considered relevant persons and have been consulted with.
Six Rivers Aboriginal Corporation (TAS)	Six Rivers Aboriginal Corporation represents Aboriginal people from the mid northern area of TAS. It is a member of The Tasmanian Regional Aboriginal Communities Alliance. The Tasmanian Regional Aboriginal Communities Alliance was developed to provide a mechanism to engage and advise Government at all levels in regard to affairs affecting Aboriginal Tasmanians. The Six Rivers Aboriginal Corporation have interests in receptors that overlap the OA and the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Six Rivers Aboriginal Corporation are considered relevant persons and have been consulted with.

Relevant Person	Justification
South Australian Native Title Services (South Australia)	SANTS is the Native Title Service Provider for South Australia, primarily funded by the National Indigenous Australians Agency. It is a not-for-profit company assisting Aboriginal people in South Australia to gain recognition and to protect their native title rights and interests. It delivers a range of services to Aboriginal Nations to achieve their social, cultural and economic aspirations. The SANTS have interests in receptors that overlap the OA and the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the SANTS are considered relevant persons and have been consulted with.
South East Tasmanian Aboriginal Corporation (**SETAC**) (TAS)	The SETAC was incorporated in 1992 and was established in response to community concerns and needs. It facilitates the empowerment of the Aboriginal people of South East TAS to make decisions that affect their lives to ensure a share in Australia's land, wealth, and resources. It aims to empower the Aboriginal people of South East TAS to contribute equitably to the nation's economic, social, and political life, with full recognition of their Indigenous cultural heritage. The SETAC have interests in receptors that overlap the OA and the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the SETAC are considered relevant persons and have been consulted with.
Southern Ocean Protection Embassy Collective (VIC)	Southern Ocean Protection Embassy Collective represent the Gunditjmara Community and Families Members, Traditional Owners of Gunditjmara Sea Country. The Southern Ocean Protection Embassy Collective have interests in receptors that overlap the OA and the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Southern Ocean Protection Embassy Collective are considered relevant persons and have been consulted with.
Tasmanian Aboriginal Centre Inc (TAS)	The Tasmanian Aboriginal Centre Inc is an Aboriginal community organisation developed in the early 1970s and funded by the federal government since 1973. It was incorporated as the Aboriginal Information Service in November 1973 and changed its name to Tasmanian Aboriginal Centre in August 1977, and officially to Tasmanian Aboriginal Corporation in 2016, but still trading as the Tasmanian Aboriginal Centre. It represents the political and community development aspirations of the TAS Aboriginal community. The Tasmanian Aboriginal Centre Inc have interests in receptors that overlap the OA and the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Tasmanian Aboriginal Centre Inc are considered relevant persons and have been consulted with.
Tasmanian Regional Aboriginal Communities Alliance (TAS)	The Tasmanian Regional Aboriginal Communities Alliance was developed to provide a mechanism to engage and advise Government at all levels in regard to affairs affecting Aboriginal Tasmanians. Eligible full members are Aboriginal Community Controlled Organisations in TAS. There are seven member organisations covering TAS and its islands: Circular Head Aboriginal Corporation in the northwest region, Flinders Island Aboriginal Association Inc on Flinders Island, Melythina tiakana warrana Aboriginal Corporation in the northeast, Parrdarrama Pungenna Aboriginal Corporation in the east coast and TAS Peninsula, Six Rivers Aboriginal Corporation in the central and northern coast, South East Tasmania Aboriginal Corporation in the southeast and Weetapoona Aboriginal Corporation on Bruny Island. The Tasmanian Regional Aboriginal Communities Alliance have interests in receptors that overlap the OA and the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Tasmanian Regional Aboriginal Communities Alliance are considered relevant persons and have been consulted with.

Relevant Person	Justification
Wadawurrung Traditional Owners Aboriginal Corporation (VIC)	Wadawurrung Traditional Owners Aboriginal Corporation is the representative body for Wadawurrung Traditional Owners. The Corporation works to support their aspirations and protect Aboriginal Cultural Heritage in accordance with the Victorian Aboriginal Heritage Act 2006. Wadawurrung Traditional Owners Aboriginal Corporation was appointed in May 2009 as a Registered Aboriginal Party under the Victorian Aboriginal Heritage Act 2006. Wadawurrung's Registered Aboriginal Party area covers over 10,000 square kilometres on the western side Melbourne and including the major regional cities of Geelong and Ballarat. This area incorporates the activities of 11 separate local councils. The Wadawurrung Traditional Owners Aboriginal Corporation have interests in receptors that overlap the OA and the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Wadawurrung Traditional Owners Aboriginal Corporation are considered relevant persons and have been consulted with.
Wagonga Local Aboriginal Land Council (NSW) (**WLALC**)	WLALC was established in 1984 under the Aboriginal Land Rights Act 1983 (NSW). The Wagonga Local Aboriginal Land Council Board advocates for greater recognition of traditional fishing rights and sees this as a fundamental custodial right. The WALAC have interests in receptors that overlap the OA and the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the WALAC are considered relevant persons and have been consulted with.
Weetapoona Aboriginal Corporation (TAS)	The weetapoona Aboriginal Corporation is a group of Tasmanian Aboriginal people from the Channel and Bruny Island who strive to protect land with cultural and heritage values and to provide Aboriginal cultural experiences and promote community through providing opportunities for TAS Aboriginal people. It is a member of the Tasmanian Regional Aboriginal Communities Alliance. The Weetapoona Aboriginal Corporation have interests in receptors that overlap the OA and the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Weetapoona Aboriginal Corporation are considered relevant persons and have been consulted with.
Commonwealth Commercial Fishing	
Australian Southern Bluefin Tuna Industry Association (**ASBTIA**)	The ASBTIA represents the Australian SBT industry. SBT catch overlaps with the EMBA. Furthermore, during consultation, TGS were informed that SBT fishers may shift focus to waters of Bass Strait towards the OA. As such, ASBTIA are considered relevant persons and have been consulted with.
Bass Strait Central Zone Scallop Fishery	This fishery operates in the Bass Strait above TAS and extends from the VIC/NSW border, around southern Australia to the VIC/South Australia border. The fishery is between the VIC and TAS scallop fisheries that lie within 20 nm of their respective coasts. Fishers need to hold statutory fishing rights allocated by AFMA to fish in the Bass Strait Central Zone Scallop Fishery. The Bass Strait Central Zone Scallop Fishery has commercial fishing interests that overlap the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Bass Strait Central Zone Scallop Fishery are considered relevant persons and have been consulted with.
Commonwealth Fisheries Association (**CFA**)	The CFA is non-profit organisation and is the peak body representing the collective rights, responsibilities, and interests of a diverse commercial fishing industry in Commonwealth-regulated fisheries. CFA and the fisheries they represent have the potential to be impacted by various activities associated with the Otway Basin 3D MC MSS. As such, CFA are considered relevant persons and have been consulted with.
Seafood Industry Australia (**SIA**)	SIA is the national body representing the Australian seafood industry as a whole. Members are from the wildcatch, aquaculture and post-harvest sectors of the Australian seafood industry. It provides services to influence Government decisions, to act as a national industry voice, to provide a marketing and communications centre to ensure the growth of the Australian seafood industry. Various commercial fisheries overlap with either the OA or the wider EMBA. As such, SIA are considered relevant persons and have been consulted with.

Relevant Person	Justification
Small Pelagic Fishery Industry Association (**SPFIA**)	SPFIA represents the interests of Commonwealth-licensed operators in the Small Pelagic Fishery. The Small Pelagic Fishery extends from the Queensland/New South Wales border, typically outside 3 nm, around southern Australia to a line at latitude 31° south (near Lancelin, north of Perth). The fishery is divided into two sub areas, east and west of latitude 146°30' due to evidence of separate stocks both east and west of TAS for jack mackerel, blue mackerel and redbait. The waters targeted by the SPFIA overlap with the OA and wider EMBA. As such, SPFIA are considered relevant persons and have been consulted with.
South East Trawl Fishing Industry Association (**SETFIA**)	SETFIA represents the interests of Commonwealth-licensed trawl fishermen in the South East Trawl Fishery and the East Coast Deepwater Trawl Sector (**ECDTS**). SETFIA is predominately a supply-based organisation but has many marketing members. One of its aims is to promote environmental stewardship and self-management and improve on-the-water practices. Commercial managed fisheries represented by SETFIA overlap with the OA and wider EMBA. As such, SETFIA are considered relevant persons and have been consulted with.
Southern Rock Lobster Limited	Southern Rock Lobster Limited's primary function is to facilitate a process to guide expenditure of Research and Development levy funds independently collected from industry by State Government agencies and leveraged via the Fisheries Research and Development Corporation. SRL's members are the South Australian Rock Lobster Advisory Council Inc (**SARLAC**), the Tasmanian Rock Lobster Fishermen's Association (**TRLFA**), the Victorian Rock Lobster Association (**VRLA**) and the Australian Southern Rock Lobster Exporters Association (**ARLEA**). Waters targeted by southern rock lobster fishers overlap with the OA and EMBA. As such, Southern Rock Lobster Limited are considered relevant persons and have been consulted with.
Southern Shark Industry Alliance Inc. (**SSIA**)	The SSIA represents interests of its Commonwealth-licenced shark gillnet and shark hook members in the Gillnet Hook and Trap Fishery. Commercial catch for the Gillnet Hook and Trap Fishery has been identified within the OA and wider EMBA. As such, SSIA are considered relevant persons and have been consulted with.
Tuna Australia (ETBF Industry Association)	Formed in 2016, Tuna Australia is the industry association representing statutory fishing right holders, fishing companies, fish processors and sellers, and associate members of the Eastern and Western Tuna and Billfish fisheries of Australia (ETBF/WTBF). Members catch more than 4,000 tonnes of tuna from Australian waters each year. Tuna catch overlaps with the EMBA. Furthermore, during consultation, TGS were informed that tuna fishers may shift focus to waters of Bass Strait towards the OA. As such, ASBTIA are considered relevant persons and have been consulted with.
Victoria Commercial Fishing	
A B Hunter Fishing Pty Ltd	A B Hunter Fishing Pty Ltd are a small commercial boating outfit located in Lakes Entrance, VIC. A B Hunter Fishing Pty Ltd has commercial interests that overlap the OA and the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, A B Hunter Fishing Pty Ltd are considered relevant persons and have been consulted with.
Abalone Council Victoria	Abalone Council Victoria is the peak body representing interests of abalone divers, quota holders and processors in the VIC wild harvest abalone fishery. Abalone Council Victoria was established to lead and manage commercial stakeholders to secure a financially viable, environmentally sustainable, progressive and growing abalone industry. The Abalone Council Victoria has commercial fishing interests that overlap the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Abalone Council Victoria are considered relevant persons and have been consulted with.

Relevant Person	Justification
Abalone Victoria Central Zone	Abalone Victoria Central Zone represent the interests of Abalone Central Zone entitlement holders on operational fishery management matters. It promotes the development of a unified and coordinated approach to operational fishery management matters by Abalone Central Zone entitlement holders and contributes to the sustainable, responsible and efficient use of the Abalone Central Zone resource. The Abalone Victoria Centra Zone has commercial fishing interests that overlap the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Abalone Victoria Central Zone are considered relevant persons and have been consulted with.
Apollo Bay Fishermen's Cooperative	The Fishermen’s Co-Op was started at Apollo Bay over seventy years by local fishermen to find markets for produce from the Bass Strait including abalone, scallops, snapper, flake (or gummy shark) and Southern Rock Lobster (crayfish). It continues to support local fishermen. The Apollo Bay Fisherman’s Cooperative has commercial fishing interests that overlap the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, Apollo Bay Fisherman's Cooperative are considered relevant persons and have been consulted with.
Eastern Zone Abalone Industry Association (**EZAIA**)	The EZAIA is a wild catch abalone industry sector that operates in the Mallacoota region of VIC. In the Eastern Zone, there are 23 licenses which are allocated 460 quota units. The EZAIA has commercial fishing interests that overlap the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the EZAIA are considered relevant persons and have been consulted with.
Seafood Industry Victoria (**SIV**)	SIV was formed in 1989 and is a not-for-profit, non-government organization, founded and funded by professional fishers and fish processors. Fishing and post-harvest sector Associations also contribute financially as SIV members. SIV members include harvesters, processors, wholesalers, retailers, and exporters of VIC seafood. SIV also represents 12 Professional Associations: Abalone Victoria (Central Zone), Apollo Bay Fishermen’s Co-op, Corner Inlet Fisheries Habitat Associations, Eastern Victoria Sea Urchin Divers Association, Goulburn River Trout Pty Ltd, Lakes Entrance Fishermen’s Co-op, Melbourne Seafood Centre, San Remo Fishermens Co-op, SeaGen Aquaculture, Southern Ocean Mariculture and Yumbah Narrawong Pty Ltd. The SIV has commercial fishing interests that overlap the OA and wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the SIV are considered relevant persons and have been consulted with.
Victorian Scallop Fisherman’s Association Inc.	The Victorian Scallop Fishermen’s Association Inc. are a collective of the Scallop Fishing Families and associated support work force based in Lakes Entrance, VIC. The waters of the VIC Scallop fishing zone extend out 20 nautical miles, offshore from the high tide water mark, excluding the bays and inlets along the coastline where commercial fishing for scallops is prohibited. The Victorian Scallop Fishermen’s Association Inc represents the interests of scallop fishermen operating within Australia’s south east waters. Members hold entitlement to operate within the Bass Strait Central Zone Scallop Fishery, the Victorian Scallop Fishery and the Tasmanian Scallop Fishery. The Victorian Scallop Fisherman’s Association Inc has commercial fishing interests that overlap the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Victorian Scallop Fisherman’s Association are considered relevant persons and have been consulted with.

Relevant Person	Justification
Western Abalone Divers Assn (Abalone Western Zone)	There are 71 abalone fishery access licences in the VIC Abalone Fishery, which is subdivided into three management zones. The licences are distributed across the three management zones, with 14 in the Western Zone, 34 in the central zone and 23 in the Eastern Zone. This means a maximum of 71 divers can operate on any particular day. Some divers harvest abalone on behalf of more than one licence holder and some holders own more than one licence. The Western Abalone Divers Association has commercial fishing interests that overlap the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Western Abalone Divers Association are considered relevant persons and have been consulted with.
Tasmania Commercial Fishing	
Scallop Fisherman's Association of Tasmania Inc (**SFAT**)	SFAT actively promotes and protects the best interests of scallop fishermen and processors and negotiates management and season arrangements with the TAS government, DPIPWE and AFMA. SFAT also monitors season harvesting and plays an on-going role in assisting industry members to maximise returns on a sustainable basis as well as regular laboratory testing of scallops to ensure that they are always safe for human consumption. The SFAT has commercial fishing interests that overlap the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, SFAT are considered relevant persons and have been consulted with.
Superfresh Scallops	Superfresh Seafoods, previously known as Allan Barnett Fishing Company, is a scallop processing business in the small fishing town of Bridport, TAS. It is also known as Superfresh Scallops. Superfresh Scallops has commercial fishing interests that overlap the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, Superfresh Scallops are considered relevant persons and have been consulted with.
Tasmanian Rock Lobster Fisherman's Association (**TRLFA**)	The TRLFA is the peak body in TAS for the commercial rock lobster fishery. The primary role of the TRLFA is to promote and represent the best interests of its members and the commercial industry as a whole. The TRLFA has commercial fishing interests that overlap the OA and wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, TRLFA are considered relevant persons and have been consulted with.
Tasmanian Seafood Industry Council (**TSIC**)	TSIC is the peak body representing the interests of wild capture fishers, marine farmers, and seafood processors in TAS. The Council works in conjunction with the industry sector groups to ensure that all sectors of industry are ecologically sustainable and make an ongoing economic contribution to the TAS economy, particularly in regional areas. TSIC has commercial fishing interests that overlap the OA and wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, TSIC are considered relevant persons and have been consulted with.
South Australia Commercial Fishing	
South Australian Rock Lobster Advisory Council Inc. (**SARLAC**)	SARLAC exists to promote the interests of the South Australian Rock Lobster Industry and is governed by a Board comprising of industry leaders from each Zone together with an independent Chairperson. It works closely with grass-roots industry participants through close association with the South Eastern Professional Fishermen's Association Inc (**SEPFA**) in the Southern Zone Fishery and also the South Australian Northern Zone Rock Lobster Fishermen's Association Inc. (**SANZRLFA**) in the Northern Zone Fishery. SARLAC takes a proactive approach SANZRLFA towards stakeholder engagement to ensure best practice in fishery management. SARLAC have fishing interests in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, SARLAC are considered relevant persons and have been consulted with.

Relevant Person	Justification
South Australian Rock Lobster Fishery	The South Australian rock lobster fishery is based on the capture of southern rock lobster. The fishery is separated into 2 zones: the South Australian Northern Zone Rock Lobster Fishermen's Association Inc. (**SANZRLFA**) in the northern zone and the South Eastern Professional Fishermen's Association Inc (**SEPFA**) the southern zone. The South Australian Rock Lobster Fishery have fishing interests in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the South Australian Rock Lobster Fishery are considered relevant persons and have been consulted with.
South Eastern Professional Fishermen's Assn Inc (**SEPFA**)	SEPFA represents the interests of the South Australian Southern Zone Rock Lobster Fishery and is governed by a Committee of industry leaders. SEPFA have fishing interests in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, SEPFA are considered relevant persons and have been consulted with.
Wildcatch Fisheries South Australia Inc.	Wildcatch Fisheries South Australia Inc. represent the commercial wildcatch fisheries in South Australia - composed of 14 distinct fisheries, with over 800 licence holders. Wildcatch Fisheries South Australia Inc have fishing interests in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, Wildcatch Fisheries South Australia Inc are considered relevant persons and have been consulted with.
Recreational Fishing	
Australian Fishing Trade Association	The Australian Fishing Trade Association is the peak body representing Australia's fishing tackle industry. It was formed in the early 1980s by independent wholesalers/distributors and manufacturers of fishing tackle and associated products in Australia. It is an Australian trade association that promotes public angling and members of the association. The Australian Fishing Trade Association have fishing interests in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Australian Fishing Trade Association are considered relevant persons and have been consulted with.
Australian Recreational Fishing Foundation (**ARFF**)	The ARFF is a not-for-profit organisation with a voluntary Board of recreational fishing strategists. It is the peak representative body to the Australian Federal Government and is a partnership between State peak fishing bodies, representative organisations and fish habitat groups. The ARFF have recreational fishing interests in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the ARFF are considered relevant persons and have been consulted with.
RecFish SA	RecFish SA is the nationally recognised peak body for the 360,000 recreational fishers in South Australia. They undertake fish stocking, citizen science, habitat enhancement and fishing clinics, to benefit recreational fishers. Membership is made up of individuals and organisations, including fishing clubs and associations, regional Recreational Fisheries Committees, coastal progress associations, and recreational fishing related businesses. RecFish SA have interests in recreational fisheries in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, RecFish SA are considered relevant persons and have been consulted with.
Tasmanian Association for Recreational fishing (**TARFish**)	TARFish is an independent peak body representing the interests of recreational marine fishers in TAS. TARFish have interests in recreational fisheries in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, TARFish are considered relevant persons and have been consulted with.

Relevant Person	Justification
Victorian Recreational Fishing Peak Body (**VRFish**)	VRFish was established after implementing recommendations outlined by a Ministerial Committee 'Recreational Fishing Peak Body Working Group' in 1995. It was established that there was a need for a single independent body to unite and represent the interests of all of VIC's recreational fishers. The Working Group determined that the peak body must be representative of fishers who engage in all forms of non-commercial fishing (except traditional aboriginal fishing). This includes sport fishing, recreational fishing, underwater fishing, subsistence fishing and bait gathering. VRFish have interests in recreational fisheries in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, VRFish are considered relevant persons and have been consulted with.
Ports and Shipping	
Flinders Ports	Flinders Ports is a private port operator and South Australia's leading port operator with seven ports located at Port Adelaide, Port Lincoln, Port Pirie, Thevenard, Port Giles, Wallaroo and Klein Point. It is based in Port Adelaide in South Australia. It is responsible for the safe and efficient operation of ports and the protection of the environment in which the ports operate. Flinders Ports have interests in the waters of the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, Flinders Port are considered relevant persons and have been consulted with.
Port of Melbourne Corporation (**PoMC**)	The PoMC is a statutory body established by the VIC Government to develop and manage the Port of Melbourne, Australia's busiest container port. The Port of Melbourne serves as a vital freight hub for Australia, including southern NSW, South Australia and TAS. The PoMC have interests in the waters of the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the PoMC are considered relevant persons and have been consulted with.
Ports Victoria	Ports Victoria (formerly known as Victorian Ports Corporation Melbourne) is a statutory authority created by the Victorian Government in 2016 following the successful completion of the lease of the commercial operations of the Port of Melbourne. Ports Victoria's responsibilities include the management of commercial shipping in Port Phillip, safe navigation in the port waters of the port of Melbourne, waterside emergency and marine pollution response, and the management of Station Pier as VIC's premier cruise shipping facility. The critical work of the Harbour Master also resides with Ports Victoria. The Ports Victoria have interests in the waters of the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, Ports Victoria are considered relevant persons and have been consulted with.
TasPorts	The Tasmanian Ports Corporation, also known as TasPorts is a state-owned company responsible for eleven TAS ports and the Devonport Airport. Port facilities under the central authority of Tasports are operated at the ports of Bell Bay, Burnie, Currie, Devonport, Grassy, Hobart, Lady Barron (Flinders Island), Smithton, Stanley, Strahan, Triabunna and Whitemark (Flinders Island). The TasPorts have interests in a variety of the biological receptors in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the TasPorts are considered relevant persons and have been consulted with.
Academic and Research Organisations	
Australian Institute of Marine Science (**AIMS**)	The AIMS is a tropical marine research centre located primarily at Cape Ferguson in the locality of Cape Cleveland, City of Townsville Queensland, Australia. Their research directly benefits management agencies, marine industries, and coastal communities throughout Australia. It is considered that AIMS is a relevant person due to the interest in the marine environment in Australian national waters which potentially intersect with the Otway Basin 3D MC MSS.

Relevant Person	Justification
Blue Whale Study Inc	The Blue Whale Study Inc conducts ecological research on blue whales and their upwelling habitats in southern Australia. They work alongside local, state and federal governments, NGOs, universities, industry and other research institutions for the conservation of blue whales. The study area of The Blue Whale Study Inc intersects with the EMBA, while their focus study species (the blue whale/pygmy blue whale) also utilises the waters of the OA. As such, the Blue Whale Study Inc are considered relevant persons and have been consulted with.
Centre for Whale Research	A non-government organisation promoting cetacean related research. The Centre of Whale Research has an interest in the marine mammals associated with the EMBA (and wider) which may be impacted by the Otway Basin 3D MC MSS.
Deakin University - School of Life and Environmental Sciences	The Deakin University - School of Life and Environmental Sciences has research areas focussed on marine biology, fisheries and aquaculture. It has four campuses across Melbourne, Geelong and Warrnambool. Students attending Deakin University may utilise waters of the EMBA for their studies and as such Deakin University are considered a relevant person and have been consulted with.
Great Australian Bight Right Whale Study	The Great Australian Bight Right Whale Study researches the endangered and migratory southern right whale species for conservation management. Research includes population biology, photo identification and underwater acoustics at Head of Bight and Fowlers Bay in the Great Australian Bight, South Australia. The study area of the Great Australian Bight Right Whale Study intersects with the EMBA, while their focus study species (the southern right whale) also utilises the waters of the OA. As such, the Great Australian Bight Right Whale Study are considered relevant persons and have been consulted with.
University of Tasmania (**UTAS**) - Institute for Marine and Antarctic Studies (**IMAS**)	The IMAS is a teaching and research institute of the University of TAS in Hobart, Tasmania. IMAS was established in 2010, building upon the university's partnership with CSIRO Oceans and Atmosphere and the Australian Antarctic Division in cooperative Antarctic research and Southern Ocean research. The Institute aims "*to improve understanding of temperate marine, Southern Ocean, and Antarctic environments, their resources, and their roles in the global climate system through research, education, and outreach*". Students attending UTAS may utilise waters of the EMBA for their studies and as such UTAS IMAS are considered a relevant person and have been consulted with.
Oil and Gas Industry	
3D Oil	The formation of 3D Oil Limited was motivated by an initial focus on the Gippsland Basin, one of the more prolific oil and gas producing region in Australia. 3D Oil currently has interests in exploration permits in the offshore Gippsland and Otway Basins of South East Australia, as well as the significant new petroleum province within the Bedout Sub-basin of the Northwest Shelf. As such, 3D Oil are considered a relevant person and have been consulted with.
Beach Energy	Beach Energy Limited is an Australian oil and gas exploration and production company based in Adelaide, South Australia. It has onshore and offshore oil and gas production in five basins across Australia and New Zealand, including In the VIC Otway Basin and Bass Basin. As such, Beach Energy are considered a relevant person and have been consulted with.
CGG	CGG is a Geoscience company providing geological, geophysical and reservoir capabilities to a broad base of customers primarily from the global oil and gas industry. CGG has interested in the Otway Basin and as such are considered a relevant person and have been consulted with.

Relevant Person	Justification
Conoco Phillips	Conoco Phillips is an American multinational corporation engaged in hydrocarbon exploration and production based in the Energy Corridor district of Houston, Texas. It is currently developing an EP to undertake exploration activities in offshore permits VIC/P79 and T/49P located in Commonwealth waters of the Otway Basin. These permits like in proximity to the OA and as such, Conoco Phillips are considered relevant persons and have been consulted with.
Cooper Energy	Cooper Energy supply gas for domestic and industrial use in South-east Australia from operations at offshore VIC in the Gippsland Basin (Sole gas field) and Otway Basin (Casino, Henry and Netherby gas fields). As such, Cooper Energy are considered relevant persons and have been consulted with.
Offshore Infrastructure	
Subco Pty Ltd	Subco Pty Ltd are undersea cable specialists with a network of cables extending from Australia to the Middle East and beyond. The Indigo Central submarine cable, off southern Australia, is owned by a consortium which Subco Pty Ltd is a member of. The Indigo Central is an advanced 4,850 km long cable system offering direct, low latency connectivity from Sydney to Perth, Australia. The Indigo Central submarine cable system passes through the OA. As such, Subco Pty Ltd are considered relevant persons and have been consulted with.
Superloop Ltd	Superloop Limited operates as a telecommunications infrastructure company. The company designs, constructs, and operates underground fibre-optic cable network. It co-owns and manages the Indigo Central submarine cable system, which is located within the OA. As such, Superloop Ltd are considered relevant persons and have been consulted with.
Recreation and Tourism	
Discover Tasmania	Discover Tasmania, also known as Tourism Tasmania, is a State Authority that is focused on brand management and generating demand for leisure visitors to the state. Discover Tasmania have interests in a variety of the biological receptors in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, Discover Tasmania are considered relevant persons and have been consulted with.
Diving Industry of Victoria Association Inc	The Diving Industry Association of Victoria was established to promote the sport of diving in VIC and to support Victorians involved in the diving industry. It liaises with Government bodies and authorities on marine conservation, environmental issues and other matters that affect the diving industry and the sport of diving in VIC. The waters targeted by members of the Diving Industry Association of Victoria intersect the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Diving Industry of Victoria Association Inc are considered relevant persons and have been consulted with.
King Island Boat Club	The King Island Boat Club is located on Grassy Harbour, King Island and provides educational, recreational and competitive water sports opportunities around King Island, including the annual Queenscliff to Grassy yacht race. The King Island Boat Club has interests within the coastal and marine areas around King Island which overlap with the EMBA. As such, the King Island Boat Club is considered a relevant person and has been consulted with.
King Island Tourism	King Island tourism looks to promote tourism on King Island through marketing and brand management. King Island Tourism have interests in a variety of the receptors in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, King Island Tourism are considered relevant persons and have been consulted with.

Relevant Person	Justification
Ocean Racing Club of Victoria (**ORCV**)	The ORCV was formed as the Cruising Yacht Club of VIC by a group of yachtsmen in 1949 and renamed in 1972. The ORCV was incorporated in 1986. The club organises and develops ocean races in VIC waters focusing specifically on the needs of ocean racers. It is a non-profit organisation, which draws its membership from major yacht clubs in VIC. The ocean races hosted by ORCV traverse the EMBA in proximity to the OA. As such, ORCV are considered relevant persons and have been consulted with.
Scuba Divers Federation of South Australia, Inc	Scuba Divers Federation of South Australia, Inc brings South Australia's recreational scuba diving shops, clubs, related NGOs and individual divers, snorkellers and free divers together to advocate for the enjoyment and preservation of South Australia's marine waters. It advises its stakeholders on all diving related matters. The waters targeted by members of Scuba Divers Federation of South Australia inc intersect with the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, Scuba Divers Federation of South Australia are considered relevant persons and have been consulted with.
SCUBA Divers Federation of Victoria	SDF VIC is the peak body for recreational scuba divers, free-divers and snorkellers in VIC. It is an association of scuba diving shops, clubs, related NGOs and individuals from across the State. The waters targeted by members of Scuba Divers Federation VIC intersect with the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, Scuba Divers Federation VIC are considered relevant persons and have been consulted with.
Southern Coast Charters (King Island Dive Adventure)	Southern Coast Charters is a fishing charter service operating out of Port Fairy, VIC. It operates charters for tuna and deep sea game fishing off the coast of VIC. The waters targeted by Southern Coast Charters intersect with the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, Southern Coast Charters are considered relevant persons and have been consulted with.
Tourism Industry Council of Tasmania	The Tourism Industry Council Tasmania is a not-for-profit organisation and is the peak body for TAS's tourism industry. It provides advocacy and leadership to the TAS tourism industry. The Tourism Industry Council of Tasmania have interests in a variety of the receptors in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Tourism Industry Council of Tasmania are considered relevant persons and have been consulted with.
South Australian Tourism Commission (**Tourism SA**)	The South Australian Tourism Commission, also known as the SA Tourism Commission, is an organisation set up by the Government of South Australia to promote tourism in South Australia. Tourism SA have interests in a variety of the receptors in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, Tourism SA are considered relevant persons and have been consulted with.
Environmental Conservation Groups	
Anglesea, Aireys Inlet Society for the Preservation of Flora and Fauna (**ANGAIR**)	ANGAIR is an active voluntary group, established in 1969 and based in VIC, dedicated to protecting the indigenous flora and fauna and maintaining the natural beauty of Anglesea and Aireys Inlet and the local environments. The ANGAIR have interests in a variety of the biological receptors in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the ANGAIR are considered relevant persons and have been consulted with.

Relevant Person	Justification
Apollo Bay Landcare Group	The Apollo Bay Landcare Group is part of Landcare. Landcare is a community-based movement that began in VIC in 1986, when Joan Kirner, then Minister for Conservation, Forests and Lands, and Heather Mitchell, then president of the Victorian Farmers Federation joined forces to create what was then called Land Care. There are currently more than 600 groups working towards the protection and rehabilitation of land, biodiversity and waterways. The Apollo Bay Landcare Group have interests in a variety of the biological receptors in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, Apollo Bay Landcare Group are considered relevant persons and have been consulted with.
Australian Coastal Society Ltd (**ACS**)	The ACS was initiated at the Coast-to-Coast Conference in TAS in 2004 as a means to communicate coastal matters between conferences and where possible take resolutions of the conference to ap propriate levels of government. The South Australian branch of ACS focuses attention on running state coastal conferences and regional workshops. The TAS branch of ACS comprises members from academic, research and community backgrounds who meet regularly to discuss coastal matters statewide and nationally. The VIC branch of ACS is heavily involved in a number of coastal and marine policy reforms happening within VIC, providing representation on a number of working groups and/or providing submissions to key pieces of polices. The ACS have interests in a variety of the biological receptors in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the ACS are considered relevant persons and have been consulted with.
Australian Conservation Foundation	The Australian Conservation Foundation is Australia's national environmental organisation, launched in 1965 in response to a proposal by the World Wide Fund for Nature for a more co-ordinated approach to sustainability. It is an independent, non-partisan, non-profit organisation focused on advocacy, policy, research and community organising, with a membership of 700,000. The Australian Conservation Foundation have interests in a variety of the biological receptors in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Australian Conservation Foundation are considered relevant persons and have been consulted with.
Australian Marine Conservation Society	The Australian Marine Conservation Society is an Australian environmental not-for-profit organisation. The key focus of AMCS is to create large marine national parks (marine sanctuaries), sustainable fisheries and protect and recover our threatened ocean wildlife, such as our sharks, seals and whales. There are several AMPs, commercial fisheries, and threatened wildlife of relevance to the OA and EMBA. As such, the Australian Marine Conservation Society are considered relevant persons and have been consulted with.
Beach Patrol 3280	Beach Patrol Australia Inc oversees a network of community beach and street cleaning volunteer groups each originated under and part of the Beach Patrol movement in VIC to help clean beaches, streets and parks. Each group is defined by its suburb, Beach Patrol 3280 is based in Warrnambool. Beach Patrol Australia Inc identified Beach Patrol 3280 as a relevant person. Beach Patrol 3280 have interests in the VIC coastline which overlaps with the EMBA and lies inshore of the OA. As such, Beach Patrol 3280 are considered relevant persons and have been consulted with.

Relevant Person	Justification
Conservation Council of South Australia	The Conservation Council of South Australia, also known as Conservation SA and Conservation Council SA, is an environmental organisation serving as a peak body, representing over 50 member groups, representing over 90,000 individual members, in the state of South Australia. It is an independent, non-profit, and strictly non-party political organisation. It informs the public and government on key environmental issues and participates in government and community processes that seek to restore and protect the natural environment. The Council liaises with industry, government departments, unions, community organisations and all political parties. The Conservation Council of SA have interests in a variety of the biological receptors in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Conservation Council of SA are considered relevant persons and have been consulted with.
Environment Tasmania	Environment Tasmania was established in 2004 primarily as a Conservation Council. It is the peak group for environment organisations in the state. It is a not-for-profit, non-partisan campaigning organisation, with member groups active on issues ranging from climate change to marine protection. Environment Tasmania have interests in a variety of the biological receptors in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, Environment Tasmania are considered relevant persons and have been consulted with.
Friends of the Bay of Islands Coastal Park	The Friends of the Bay of Islands Coastal Park is part of Landcare. There are currently more than 600 groups working towards the protection and rehabilitation of land, biodiversity and waterways. Friends of the Bay of Islands Coastal Park has interests that overlap the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, Friends of the Bay of Islands Coastal Park are considered relevant persons and have been consulted with.
International Fund for Animal Welfare (**IFAW**)	The IFAW is one of the largest animal welfare and conservation charities in the world. The organization works to rescue individual animals, safeguard populations, preserve habitat, and advocate for greater protections. The IFAW has interests in environmental receptors that overlap the OA, and the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the IFAW are considered relevant persons and have been consulted with.
King Island Landcare Tasmania	The King Island Landcare Tasmania is part of Landcare. There are currently more than 600 groups working towards the protection and rehabilitation of land, biodiversity and waterways. King Island Landcare Tasmania have interests in a variety of the biological receptors in the wider EMBA which may be impacted in the unlikely event of a fuel spill, and as such King Island Landcare Tasmania are considered relevant persons and have been consulted with.
Marine Mammal Foundation	The Marine Mammal Foundation is a not-for-profit scientific and education organisation protecting the marine environment through research, community engagement, and education. Several species of marine mammal have been identified as potentially present within the OA and wider EMBA, and as such, the Marine Mammal Foundation are considered relevant persons and have been consulted with.
Otway Climate Emergency Action Network (**OCEAN**)	OCEAN is an environmental activist group from Apollo Bay and the Otway Ranges. Its main goal is to inform Australians about the impacts of gas exploration in the Otway Basin. OCEAN self-identified to TGS as part of the consultation process. The main focus area of OCEAN includes the OA and wider EMBA. As such, OCEAN are considered relevant persons and have been consulted with.

Relevant Person	Justification
Port Phillip EcoCentre	Port Phillip EcoCentre is a not-for-profit, community-managed environment group located in the corner of St Kilda Gardens, Melbourne. For over 20 years it has provided a base for affiliate groups involved in activities that promote environmental sustainability and community action. The Port Phillip EcoCentre has interests in environmental receptors that overlap the OA, and the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Port Phillip EcoCentre are considered relevant persons and have been consulted with.
Surfers for Climate	Surfers for Climate is an Australian charity dedicated to raising awareness on climate change. Surfers for Climate has interests in environmental receptors that overlap the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, Surfers for Climate are considered relevant persons and have been consulted with.
Surfrider Foundation Australia	Surfrider Foundation Australia is a registered not for profit sea-roots organisation founded in 1991 dedicated to the protection of Australia's marine waters and beaches through conservation, activism, research and education. Surfrider Foundation Australia self-identified to TGS as part of the consultation process. The Surfrider Foundation Australia has interests in environmental receptors that overlap the OA, and the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, the Surfrider Foundation Australia are considered relevant persons and have been consulted with.
Tasmanian Conservation Trust	Tasmanian Conservation Trust is TAS's oldest non-profit conservation organisation, formed in 1968. The Tasmanian Conservation Trust works to preserve TAS's biodiversity, natural values, built and cultural heritage. The Tasmanian Conservation Trust have interests in a variety of the biological receptors in the wider EMBA which may be impacted in the unlikely event of a fuel spill, and as such, the Tasmanian Conservation Trust are considered relevant persons and have been consulted with.
The Wilderness Society	A non-government organisation advocating conservation and may have functions, interests and activities in the EMBA associated with the biological environment. The Wilderness Society is an Income Tax Exempt Charity across all states/territories in Australia. The Wilderness Society has an interest in a variety of the biological environment receptors in the wider EMBA which may be impacted in the unlikely event of a fuel oil spill. It is considered that the influence of this relevant person is low. ADD MORE – HAVE THEY BEEN CONSULTED WITH?
Warrnambool Coastcare Landcare Network Inc	Warrnambool Coastcare Landcare Network is a volunteer community organisation working to improve biodiversity in Warrnambool and district and advocating for the protection of the natural environment. Warrnambool Coastcare Landcare Network have interests in a variety of the biological receptors in the wider EMBA which may be impacted in the unlikely event of a fuel spill. As such, Warrnambool Coastcare Landcare Network Inc are considered relevant persons and have been consulted with.

TGS acknowledges that new relevant persons can be introduced at any time throughout the duration of the EP and the flexible and adaptive consultation methodology within this EP (**Section 5.5.1**) can accommodate such introductions through the Management of Change process (**Section 10.4.6**).

5.5 Relevant Persons Consultation Programme and Methodology

5.5.1 Overview

The consultation programme has been designed in accordance with the Object of Regulation 3 of the Environment Regulations, which is to ensure that any petroleum activity or greenhouse gas activities carried out in an offshore area is:

a) Carried out in a manner consistent with the principles of ESD as set out in section 3A of the EPBC Act; and

b) Carried out in a manner by which the environmental impacts and risks of the activity will be reduced to as low as reasonably practicable; and

c) Carried out in a manner by which the environmental impacts and risks of the activity will be of an acceptable level.

As noted in the Guidance Document, the process of preparing an Environment Plan is an iterative one. The design of the consultation programme specifically recognises and accommodates this iterative process, whereby additional information may be received that may require further consultation processes to be undertaken, including with additional relevant person(s). The relevant person consultation programme led by TGS is continuing for the duration of the EP. The consultation programme has and continues to provide a mechanism for information and knowledge exchange between TGS and relevant persons regarding the proposed Otway Basin 3D MC MSS as well as understand the values and sensitivities of each relevant person. TGS has provided the opportunity for relevant persons to ask specific questions, provide feedback, have meetings and transparent, open and honest communications as captured in **Appendix H**. Further, the information exchanged during consultation has provided TGS with an understanding of the potential risks and impacts the Otway Basin 3D MC MSS poses on the functions, interests, and activities of relevant persons. This information has informed TGS' planning and execution of the Otway Basin 3D MC MSS, including development of suitable controls to avoid or mitigate risks and impacts. Consultation with relevant persons also assisted in understanding and developing the methodologies for identifying all relevant persons and providing sufficient information and reasonable timeframes.

Consultation for the Otway Basin 3D MC MSS identified 163 relevant persons which includes government agencies, academic and research organisations, ports and shipping organisations, non-government agencies, fisheries, tourism and recreational groups, traditional owner groups, native title holders, environmental groups, offshore infrastructure companies and petroleum and exploration companies. TGS managed this information throughout the consultation program in a register, which consisted of contact details, date of last activity and a consultation 'status' to indicate whether the relevant person required further contact or not. A summary list of relevant persons that have been contacted as a component of the relevant persons consultation programme for the Otway Basin 3D MC MSS is provided in **Appendix G**.

5.5.1.1 Transparency and Record Keeping

TGS is required to ensure full transparency is maintained during the relevant persons consultation process. This is to allow NOPSEMA to determine whether consultation has been undertaken appropriately and in accordance with the requirements of the Environment Regulations. Environmental Regulations 16(b)(iv) requires TGS to include a copy of the full text of any response that has been submitted by a relevant person, within the final EP. To this end, the unedited versions of all correspondence with all relevant persons that formed part of the relevant person consultation process is provided in **Appendix H.**

In addition to this, where verbal communications between TGS and relevant persons have occurred, meeting minutes and phone records were generated to document the consultation. This documentation of the consultation is consistent with the requirements of the 2011 Explanatory Statement to the Environment Regulations, which states that the summaries included from relevant person consultation should promote transparency of all levels of consultation undertaken. These minutes and phone records have been included within **Appendix I**. Further, there were several information sheets distributed to relevant persons as part of the consultation programme, and these are included within **Appendix J**.

Relevant persons are informed that they may advise TGS that particular information they provide is sensitive and request that information not to be made public. Where such requests are made, TGS ensures that information subject to that request is not made public. TGS has provided this explanation within each of the factsheets that has been disseminated and announced at the commencement of each meeting.

5.5.1.2 Methodology Overview

The consultation program methodology has changed and developed as TGS has incorporated experience, learnings and improvements while consulting with relevant persons. Initially (prior to 2023), the consultation process focused on commercial fishing groups and involved briefings and disseminating an information sheet that provided an overview of the Otway Basin 3D MC MSS and information relevant to commercial fishers. This initial consultation was intended to be generic and provide a high-level overview for the relevant person to decide whether they required more information to assess the possible consequences of the activity on their functions, interests or activities.

Following this initial stage of the consultation, from January 2023 the consultation process expanded broadly to encompass a wide range of relevant persons (as detailed in **Section 5.4.5.2**). Consultation commenced (or continued with the existing commercial fishing groups) with emailing an information sheet that introduced marine seismic surveys and provided an overview of the Otway Basin 3D MC MSS. As with the initial stage, this consultation was also intended to be generic and assist the relevant person to decide whether they required more information to assess the possible impacts of the activity on their functions, interests or activities.

Depending on the response from the relevant person, TGS would then either:

- Follow up with another email or phone call (if no response was received) to ask if the relevant person would like additional information or to meet with TGS and discuss further; or
- Provide additional information as requested and in most cases an offer to meet with TGS to discuss their concerns further.

TGS acknowledged all responses, including those persons that did not consider themselves relevant or requested to be removed from the consultation program.

Where requested and possible, TGS provided the specific information requested for each of the relevant persons. Information requests varied from specific details about the seismic survey operation, e.g. equipment, location (GPS coordinates, shapefiles etc) and timing, to requests for specific control measures to mitigate impacts from certain survey aspects or requests for assistance with related research. TGS experienced some challenges related to timing, where requests for information could not be satisfied as the Environment Plan was still being developed and the survey planning was changing often with new information arriving as a result of consultation or further research.

Allowing the relevant person to specify the information that they consider necessary to assess the possible consequences of the activity ensures that they are actively involved in developing a tailored consultation process. If it was identified that insufficient information was provided in the initial round of consultation, revised and targeted information was developed and provided where required following the Appeal Decision and Guidance Document being released.

This process will also add to the understanding of what level of information specific groups of relevant persons need for future applications, resulting in increased industry knowledge.

5.5.1.3 Providing Sufficient Information to make an Informed Assessment

As detailed within the Guidance Document, information provided to relevant persons must be sufficient to allow an informed assessment of the possible consequences of the activity on the functions, interests, or activities of the relevant person. The level of this information required and provided varied for different relevant persons depending on the degree to which a relevant person is affected and interested.

The consultation programme is an iterative process. Central to this, and as noted in the Guidance Document, the provision of information to relevant persons is also an iterative process. In turn, the iterative process serves to inform the 'decisional choice' that TGS has applied to consultation with relevant persons. This means that the decisional choice for each iteration provides relevant person(s) with finer detail and precision on a case-by-case basis, such that relevant persons consulted have the most appropriate information about the Otway Basin 3D MC MSS as it relates to their own functions, interests or activities, and relevant person(s) are given the best opportunity to outline what information needs they have and have the ability and opportunity to request that from TGS.

For all relevant persons, sufficient information is defined as the provision of information as requested by the relevant person(s), to their satisfaction that concerns and queries have been addressed in good faith, and in a timely fashion to facilitate further discussion and enable relevant persons to disseminate information to their own stakeholder groups. This is further considered as information that provides enough detail and information to enable the relevant persons to understand the proposed activity and determine whether the proposed activities (both planned and unplanned) may impact any of their values, sensitivities, or commercial activities.

Given the broad requirements across relevant persons, sufficient information may require personalised and targeted communications, with multiple (more than two) follow up consultations. An example of targeted communications that TGS has provided to relevant persons is the provision of GPS coordinates of the OA in a Microsoft Excel spreadsheet to commercial fishers so they can copy the coordinates straight into the chart plotting software. This not only makes it easier for the fishers but also avoids any transcription errors.

Likewise, the information sheet distributed to Traditional Owner groups differs to the more general information sheet, so TGS has targeted the audience/relevant persons, and sought feedback from key groups consulted as to whether the information provided was sufficient to meet the needs of informing relevant persons. Information within the correspondence undertaken and phone calls held provided further context of the proposed activities as well as the potential for an unplanned activity to occur (i.e. fuel oil release following the rupture of the vessels fuel tank(s)), and what area of the receiving environment may be impacted should an unplanned activity eventuate (i.e. the area covered by the EMBA).

Information was adapted to incorporate feedback from relevant persons for additional information or no suggestions of additional information that should be included was provided by any of the relevant persons that were asked directly whether the information was appropriate. This also includes multiple attempts by TGS to confirm with relevant persons if the information is adequate and if different information is required. As a result, TGS considers that the information provided as part of the consultation process was sufficient to enable relevant persons to make an informed decision as to whether their values and sensitivities or commercial interests would be impacted from the Otway Basin 3D MC MSS. Providing sufficient information allowed relevant persons to make an informed decision as to whether they wanted to provide feedback on the proposed activity or not. The different information sheets distributed to the relevant persons are provided in **Appendix J**.

In general for the 'inform and seek feedback' level of consultation the information provided was considered to be sufficient in accordance with the notification requirements, under the regulatory requirements and guidelines and TGS's commitment to providing sufficient information for relevant persons to make an informed decision on TGS's proposed activity (**Section 5.1**).

TGS has deemed that a relevant person has been provided sufficient information if through follow up communications there has been no change in the level of decisional choice following each iteration (i.e. no change in the finer detail or precision of information requested by the relevant person(s)) and no further iterations to case-by-case consultation have been deemed necessary.

5.5.1.4 Providing a Reasonable Period to make an Informed Assessment

Regulation 11A(3) states titleholders must provide a "*reasonable period*" for the relevant person to make an informed assessment of the possible consequences of the proposed activity on their functions, interests or activities so they are able to respond with any concerns (para. 56 of the Appeal Decision). However, no discernible definition as to what is considered a 'reasonable period' to support adequate relevant person feedback is provided in the Environmental Regulations, and it is acknowledged that this is assessed on a case-by-case basis, depending on the corresponding requirements for more detailed (or not) further information and consultation efforts. Thus, the provision of a "reasonable period" is inherently linked to the iterative process described above for providing sufficient information and is accommodated into the overall consultation programme on a case-by-case basis.

All relevant persons were contacted, at a minimum, on two separate occasions. As noted throughout this section, where relevant persons have requested further consultation, this has been accommodated on a case-by-case basis. The timeframes between the initial email communications and follow up communications with relevant persons was highly variable, and thus a generalised time period between first and second round communications was not a 'one-size-fits-all'. TGS introduced suggested dates for relevant persons to provide feedback by in order to keep the process progressing, however would always reassure relevant persons they could have additional time if required. It is considered that multiple attempts to engage and the provision of subsequent updates regarding the survey details and any changes/revisions is characterised as a "*reasonable period*" to support relevant person feedback. Where no response has been received following the passing of a "*reasonable period*", this has been recorded within the communications correspondence (**Appendix H**) as ongoing or continuing consultation and TGS continues to contact the relevant person by providing updates and opportunities to contact TGS. In more recent correspondence, TGS has asked persons to advise them if they no longer wish to be contacted and removed from the consultation process and several persons have requested this.

As outlined within **Section 5.4.5**, a system has been developed as a starting point for consulting with relevant persons. Where relevant persons identified the need for additional time to adequately assess the potential impacts from the Otway Basin 3D MC MSS on their functions, interests, or activities, this was then worked through with them on a case-by-case basis to ensure a bespoke consultation process was accommodated. Although this was undertaken as part of initial consultation, a follow-up with each relevant person was undertaken to provide further updates to the project and provide the relevant person(s) with a further opportunity to engage with TGS about how their functions, interests or activities may be impacted by the Otway Basin 3D MC MSS. By reaching out on multiple occasions this accounts for potential availability or accessibility issues that the relevant person may have and ensures a lack of response is not attributed to incorrect contact details.

Where there has been no response from a relevant person, TGS has researched alternative contacts through questioning other relevant persons or further internet or database searches.

TGS also notes feedback from the Regulator and relevant persons, including peak industry representative bodies, regarding the possible impact of 'fatigue' on the amount of consultation. Given the number and frequency of similar projects proposed and occurring within the broader SEMR, it is understood from relevant persons consulted as part of preparing this EP that many relevant persons have received a high volume of communications from titleholders, resulting in decreased capacity and willingness to consult. With respect to this constraint, TGS acknowledges the relevant person's comments and advises them they will remain within the consultation program to continue to receive updates and an invitation to contact TGS at any time throughout the project with any comments or queries. Other offers to assist with consultation fatigue was provided by TGS, including targeted, concise, and fit-for-audience information to make communication/understanding easier, and in order to develop relations and build trust and reliability for this Seismic Survey, and future applications. Additional time was provided where requested to account for the consultation fatigue felt by some of the relevant persons.

5.5.2 Level of engagement

Identified relevant person(s) have been prescribed a level of consultation based on their individual requirements. This has been a bespoke basis, and as stated above, not a 'one-size-fits-all' approach is applicable. The effort of consultation across relevant persons was therefore variable, and dependent on individual requirements. These levels of consultation effort can be best described as either 'involved', 'consult' or 'inform' based on the anticipated area of interest and the functions, activities, or interests of individual relevant person(s). These levels of effort are described in general terms as follows:

- An 'involved' or 'pro-active' level of consultation effort for relevant persons(s) is whereby TGS works directly with relevant person(s) throughout the consultation process to ensure that concerns, queries, and requests for information by relevant person(s) are consistently understood and considered. This consultation was targeted based on the relevant specific areas associated with their functions, interests, and activities, and where required the relevant persons were involved in the development of control measures. The intention of this consultation is to seek direct feedback on the proposed Otway Basin 3D MC MSS with a focus on understanding the values and sensitivities of each relevant person and ensuring potential impacts to those values and sensitivities are mitigated through control measures and commitments made in the EP;

- Consultation effort described as a routine ‘consult and seek feedback’ level of consultation, is where TGS seeks to gather feedback from relevant person(s) to understand values and sensitivities should the relevant person(s) consider they are impacted by the Otway Basin 3D MC MSS. The intention of this consultation is to seek direct feedback on the proposed Otway Basin 3D MC MSS with a focus on understanding the values and sensitivities of each relevant person and ensuring potential impacts to those values and sensitivities are mitigated through control measures and commitments made in the EP; or
- Consultation relevant persons requiring a lower effort as an ‘inform and seek feedback’ level of consultation, is where TGS provides relevant person(s) with balanced and objective information to assist them in understanding the activity, impacts and controls. Opportunity to provide feedback or ask for further information that may be relevant to their functions, interests, or activities, is provided through TGS communication channels. The intention of this consultation is to seek direct feedback on the proposed Otway Basin 3D MC MSS from those persons that are not actively known at the time and provides an opportunity for relevant persons who have not been identified to self-identify and provide information on any values and sensitivities they may have. If any feedback is received, TGS will review with the intention of ensuring those values and sensitivities that have been raised are mitigated through control measures and commitments made in the EP. Public notification through newspaper advertisements is the most likely way this will take place and will be ongoing through the EP process as part of the continuing consultation process.

Table 40 sets out the key activities, tools, information provided, and justifications for each Category of relevant persons. It is noted here, that depending on individual requirements, relevant persons information packages and follow up consultation are combinations of tools/activities and have been based on the whether the relevant persons needed/wished to continue the consultation (i.e. additional activities/tools were not used if the relevant person did not identify the Seismic Survey as a concern to them).

Table 40 Consultation Activities and Tools across different levels of effort of consultation for relevant persons

Level of consultation effort	Activity / Tool	Information provided	Timeframes and Justification*
Involved level of consultation	Direct consultation 'Face to face' meetings or via online meeting Organised phone calls Follow up calls/video conferencing Ongoing email exchanges	Targeted and specific Information EP publication notification (national, state regional) Individual email /email follow ups Meeting minutes Phone records	Multiple communication attempts (minimum 2, and more as required), including pre-activity, and post activity notification processes. Timeframes are to be ongoing if required on a case-by-case basis.
Consult and seek feedback level of consultation	Email exchanges as required or requested by Category B relevant persons Phone calls or video meetings as requested by relevant persons	Information sheet EP publication notification (national, state regional) Email exchanges/email summaries	Multiple communication attempts (minimum 2, and more as required), including pre-activity, and post activity notification processes. Timeframes may be extended if requested.
Inform and seek feedback level of consultation	Notification via public media outlets (i.e. newspaper notices with request for feedback to the TGS email address included within notice.	Information sheet EP publication notification (national, state regional)	Minimum two separate occasions, generally variable periods of time across the initial and follow up communication

All efforts that have been undertaken as part of the consultation process are included within Appendix H and Appendix K. These appendices note the attempts that have been made despite no response in some instances.

For relevant persons requiring active 'involved and/or 'seek feedback' levels of effort, targeted consultation since early 2023 with relevant persons was initiated by TGS to identify their level of interest in the project, potential impact from the project and to begin developing control measures (if needed) to address their concerns with respect to the Otway Basin 3D MC MSS. Consultation with these relevant persons remains ongoing through the EP evaluation process and will continue for the duration of the EP. Any feedback provided by a relevant person will be carefully considered and if a change is required, will be done so through the management of change process. Any communications or feedback received is logged as part of the continuing consultation register.

For the 'inform and seek feedback' level of consultation for relevant persons, all notifications will be undertaken in accordance with statutory timeframes for public notification under the regulations (see **Section 5.1**). In addition, these notifications will also be ongoing through the newspaper advertisements that will be placed in relevant newspapers that also informs those potentially relevant persons that were not known at the time of preparing the EP. Should any feedback be provided, it will still be considered and incorporated where relevant through the management of change process.

The consultation programme with relevant persons comprised of the following phases:

- Targeted relevant persons consultation (mid 2022) focusing on commercial fishing groups that included disseminating an information sheet providing an overview of the proposed activities and location details (see **Section 5.5.3**);
- Targeted and bespoke relevant persons consultation (from early 2023) scope expanded to include the following groups;
  - Academic and research organisations;
  - Government agencies and departments;
  - Commercial fishing groups;
  - Environmental groups;
  - Petroleum and gas entities;
  - Offshore infrastructure entities;
  - Ports and shipping entities;
  - Recreation and tourism groups;
  - Recreational fishing groups;
  - Traditional Owner groups; and
  - Other relevant persons self-identified, such as individuals.
- Pre-activity notification;
- Continuing relevant persons consultation; and
- Post-activity notification.

At the outset, general consultation material was disseminated to all relevant persons to initiate communications between the proponent and relevant persons, provide an opportunity to establish a meeting and to introduce the proposed Otway Basin 3D MC MSS. Using the information gained during the relevant persons identification process and based on feedback received regarding the information sheet, key relevant persons were identified for specific consultation. The nature of specific consultation is such that it's tailored to, and therefore highly variable amongst the range of specific relevant persons. Specific consultation may include increased frequency of communications or more detailed communications regarding the potential impacts to the relevant persons activities or a change in the mode of communications (for example, phone versus email) utilising the general activities/tools identified in **Table 40**.

Of note, is that not all general consultation communications occurred concurrently. As the development of the EP progressed, new sensitivities, receptors and corresponding 'relevant persons' were subsequently identified. Where this occurred, additional relevant persons were contacted as soon as reasonably possible to notify them of the proposed Otway Basin 3D MC MSS and, therefore, were communicated on an as needs basis.

As a result of the consultation programme and ongoing follow up with those that have not responded, TGS is confident that it has provided relevant persons with sufficient information to make an informed assessment, as well as providing a reasonable period for each relevant person to consider all the information received and provide any feedback for TGS to assess any claims raised and implement any additional controls as required.

5.5.3 Information Sheet

To support the consultation with relevant persons, an information sheet was developed to introduce relevant persons to marine seismic surveying and provide an overview of the proposed Otway Basin 3D MC MSS, including location of the OA, AA and EMBA, survey vessels and equipment, examples of key control measures and to invite relevant persons to provide feedback and contact TGS with their queries and concerns. The relevant persons identified were contacted via email and provided with the information sheet in mid-2022 (**Appendix H**). This information was subsequently made available to relevant persons as they were identified throughout the development of the EP and as a result of the wider consultation process with relevant persons.

The following information was provided to all relevant persons within the information sheet:

- A high-level description of the proposed location of the Otway Basin 3D MC MSS;
- Description of the proposed seismic activity;
- TGS' commitment to communication during the Otway Basin 3D MC MSS;
- TGS' commitment to environmental performance;
- A request to all relevant persons for feedback on the Seismic Survey with full contact details of TGS' representatives provided;
- Location map of proposed OA and EMBA; and
- Reassurance that sensitive information will not be made public if a relevant person informs TGS their information is confidential and not to be made available to public.

When the information sheet was initially sent out to the relevant persons identified first, the size of the AA and OA were larger than the current proposed Otway Basin 3D MC MSS OA and OA. However, with the subsequent reduction in the AA and as the survey specifications were refined and updated, the information sheets and assessment of sensitivities in the EMBA were concurrently updated.

As the consultation and EP process progressed, the information sheet was further refined to address re-occurring queries raised by relevant persons or other learnings, such as clarification of terms or operations. Additionally, a separate information sheet was developed for traditional owner groups that could be further distributed within their communities. In total, four versions of information sheets have been disseminated during the consultation program and copies of these are provided in **Appendix J**.

5.5.4 General Relevant Persons Consultation (mid-2022 to early 2023)

The consultation process sought to initially focus primarily on the functions, activities, and interests of commercial fishing license holders, as well as peak industry body representatives of the commercial fishing industry. After the relevant persons for this were identified, the consultation process commenced in mid-2022. **Table 41** summarises the key consultation events undertaken with commercial fishing groups. This included a series of information briefings, introductory sessions, and targeted meetings with individual commercial fishing industry groups. The process sought to determine what environmental and social values, sensitivities, access rights, commercial interests, risks, and impacts were of most concern to relevant persons in relation to the Otway Basin 3D MC MSS and to establish a precedent for mutual sharing of information between all parties.

Table 41 Key Commercial Fisheries Consultation Events 2022

Stage	Timing	Information Provided
Initial Notification	May 2022	A notification was distributed to stakeholders providing information on the 3D MSS, and associated EP. An information sheet with map was issued.
Call with SETFIA	23 May 2022	SETFIA attended a call with TGS in which a service of SETFIA assessing the overlap of the EP Area with relevant fisheries was discussed.
Commercial Fisheries Briefings	2, 9, 10 and 29 June 2022	Briefings for commercial fisheries with interests potentially overlapping the EP Area were conducted via Microsoft Teams. Briefings included overview of the proposed Otway Basin 3D MC MSS and EP, commercial fishing effort for relevant Commonwealth and State fisheries based on available data, invited questions and discussions, and outlined ongoing engagement. **Note:** no one attended the briefing on 10 June 2022 and, as such, there are no corresponding meeting notes.
Meeting with TSIC	4 July 2022	Meeting with TSIC conducted via Microsoft Teams. Included briefing on the proposed Otway Basin 3D MC MSS and EP, commercial fishing effort based on available data, invited questions and discussions, and outlined ongoing engagement.
Meeting with SRL	5 July 2022	Meeting with SRL conducted via Microsoft Teams. Included briefing on the proposed Otway Basin 3D MC MSS and EP, commercial fishing effort based on available data, invited questions and discussions, and outlined ongoing engagement.
Meeting with ASBTIA	7 July 2022	TGS met in person with ASBTIA CEO in South Australia on 7 July 2022
Fishers in the Tasmanian giant crab and rock lobster fisheries	31 August 2022 7 September 2022	Meetings with representatives from the Tasmanian giant crab and rock lobster fisheries conducted via Teams. Included a briefing on the proposed Otway Basin 3D MC MSS and detailed the giant crab exclusion zone to be implemented during the survey. Invited discussion and input regarding EP.

This initial round of consultation with relevant persons consisted of introductory information presented via emails with an appended information sheet, as well as information briefings and targeted meetings. All relevant persons were encouraged to engage, ask questions, and invited to provide comment or request additional information if they required it. All meeting attendees and email recipients were advised that any information determined to be sensitive will not be made public and were asked to inform TGS if any information is not to be made available to the public.

A record of all feedback received from relevant persons and the responses provided by TGS is summarised in **Appendix K**. Meeting minutes including records of attendance are provided in **Appendix I.**

Where feedback received from relevant persons during this initial phase was assessed as relevant for specific information requirements to be included in the EP, or for specific control measures, these have been assessed and incorporated as required. For example, these include the disseminating of GPS coordinates, implementing a 48-hour operational look ahead plan of look-ahead and notification requirements for planned activities. Feedback from this general consultation with relevant persons was rolled across to targeted and bespoke consultation from the start of 2023, and is ongoing for the duration of the EP.

5.5.5 Relevant Persons Consultation from early 2023 onwards

Consultation continued from early 2023 with a series of targeted information searches to increase the consultation scope to include other groups of relevant persons. A reduction in survey area, prompted a review of modelling that determined the EMBA discussed in **Section 5.4.3** and a revised EMBA was produced in early 2023. The revised EMBA resulted in a review of the consultation approach and who was considered as a relevant person.

This process used the sources of information described in **Section 5.4** and resulted in several key groups being identified, including an expanded group of commercial fisheries, Traditional Owner groups and environmental groups. The full list of relevant persons which were updated by the revised EMBA are included within **Appendix G**. Consultation efforts were increased during February to disseminate information to as many identified relevant persons as possible within the revised and expanded scope, with the intent that this would also facilitate further identification of other relevant persons.

Targeted email campaigns were carried out between 13 – 16 February, to 107 relevant persons across the full range identified to date. This included the relevant persons previously identified during the 2022 general consultation period, as well as existing/known relevant persons identified from a previous EP process for the same regions (Otway 2D MSS).

Consultation during the middle of February 2023 also focussed heavily on efforts to engage with Traditional Owner groups, local councils, and environmental groups, via email, online meetings, and several in-person meetings. Following the February consultation effort, subsequent follow up consultation with relevant persons was implemented on an iterative and case-by-case basis, as described in **Section 5.4.**

For relevant persons who had not responded to initial emails issued during February (and for any relevant persons identified after this period), individual follow up emails were sent to each relevant persons to ask if the relevant person had any comments or queries or required additional information. A customised email response was also sent to those relevant persons who expressed interest in the proposed Otway Basin 3D MC MSS during the first round of consultation, including further high-level information relating to their potentially impacted activities where required.

Following the initial efforts for the targeted consultation, further relevant persons were identified via the relevant persons identified to date. All details of consultation undertaken to date are provided in **Appendix K,** with the assessment of merit of any claims or objections provided in **Appendix K.**

The online and in-person meetings were delivered with the following format:

- Introduction – welcome, introduction of attendees and purpose of meeting;
- Background information about marine seismic surveying;
- Project overview – location, equipment, timing, duration;
- Environmental planning process:
    - Assessment of existing values and sensitivities;
    - Identification of risks and impacts;
    - Determination of control measures;
- Consultation process with the relevant person; and
- Questions and discussion.

At the start of every meeting, the relevant person was advised that TGS was documenting the information from the meeting and to inform TGS if there was any sensitive information that should not be made available to public. Following the meeting, TGS would email the meeting minutes and a copy of the presentation delivered at the meeting and any additional information requested at the meeting and invitation to review the meeting information and advise of any amendments or sensitive information to be removed from public consultation.

5.5.6 Specific Relevant Persons Consultation – Commercial Fishing Industry

The commercial fishing industry is the primary relevant persons with a commercial interest in the maintenance of access to and the condition of the marine environment (e.g. conservation of aquatic resources) within and surrounding the OA. There are multiple licence holders that undertake fishing activity within the OA and who have the potential to be directly impacted by the proposed Otway Basin 3D MC MSS. In contrast, licence holders that undertake fishing activity within the EMBA have the potential to be impacted in the unlikely event of a fuel oil spill.

Consultation with the commercial fishing industry is nuanced due to the multiple tiers in which the functions, interests and activities of commercial fishers are regulated, managed, and represented (Commonwealth of Australia, 2022). As a result, consultation was commonly undertaken with the commercial fishing industry through the consulting some or all of the following relevant persons, as appropriate and in accordance with the method outlined in **Section 5.4**:

- Commonwealth and State industry departments who coordinate the authorisation of commercial fisheries licences, fisheries management and surveillance/enforcement programs within the Australian Fishing Zone and State coastal waters, respectively;
- Peak industry associations and representative bodies who represent the interests and/or activities of commercial fisheries license holders and have authority to consult on behalf of all their members; and
- Commercial fishing license holders (‘commercial fishers’) who may have entitlements to fish within the EMBA.

A preliminary review of fisheries boundaries showed overlap between the extent of both Commonwealth and State fisheries, the OA and EMBA, as described in **Section 4.7.3** and a summary of catch effort data is set out in **Section 4.7.3.1**. To inform the specific relevant persons consultation activity, a detailed assessment of fishing activity within the OA and EMBA was completed using data extracted from ABARES, VFA, DNRET and PIRSA and has been reviewed to further understand the fisheries that are active in waters overlapping and adjacent to the OA.

In addition to reviewing fishing effort data, TGS commissioned SETFIA to compile an additional review of the level of catch made by the relevant Commonwealth and State-managed fisheries within the OA, the proportion of each fisheries’ total allowable catch and the annual average catch value that it represents (based upon data from the ten years prior to 2021).

TGS has also engaged TSIC as subject matter experts to support consultation with Tasmanian seafood operators, liaising with the relevant commercial seafood operators to ascertain and provide feedback to TGS on the potential impacts and concerns about the survey from the industry. Additionally, TSIC will also provide follow-up information and updates to commercial seafood operators from TGS, as requested.

Determining the function of peak industry associations and representative bodies as it relates to consultation on behalf of all their members was important, though challenging. Peak industry associations and representative bodies are variably resourced and experienced in their capacity to respond to titleholders regarding offshore project proposals. However, they maintain independent and effective relationships with those they represent and are also aware of and respect the industry's sensitivity to the overwhelming level of requests for feedback they are currently experiencing from the many proponents required to engage with them. Hence, TGS has experienced varying levels of maturity in processes regarding consultation among these relevant persons.

As a default, peak industry associations and representative bodies were determined to be relevant persons in their own right. An effort was made to ascertain the nature of their delegations to consult with TGS on behalf of all their members, prior to contacting commercial fishing license holders. In some cases, peak industry associations and representative bodies had developed processes for consultation with license holders.

Where practicable, TGS sought to engage with peak industry associations or representative bodies in a transparent manner to ensure the best outcome for commercial fisheries was achieved. As with other relevant persons, this meant balancing the requirements between AFMA and SETFIA, whilst ensuring consultation remained ongoing with commercial fishers represented by these industry groups. For other industry groups, targeted and continuing consultation with TSIC, VFA, SIV and Southern Rock Lobster Ltd was also continued to ensure full representation of relevant persons in the continuing consultation programme, and recognising that many of these groups were at limited capacity to fully engage.

In the absence of a peak industry association or representative body, TGS has conservatively assumed that license holders must be consulted with directly. Additionally, that this consultation was broad enough to capture those with the entitlement to fish.

Likewise, where a peak industry association or representative body or the licensing authority determined it to be required, license holders were consulted in accordance with methods outlined in **Section 5.5.5**. For example, at the start of the EP process, TGS consulted with SETFIA, the peak industry body representing the trawl fisheries license holders. It was acknowledged that whilst SETFIA was a significant peak industry body, SETFIA itself did not want to undertake consultation with its members on behalf of TGS. Whilst AFMA were able to provide details of individual license holders represented by SETFIA, SETFIA were subsequently not in support of AFMA providing individual member details to TGS for this purpose.

Hence, a number of efforts were made to communicate directly with commercial fishers, but this proved difficult.

Responses from representatives of Commonwealth Fisheries, State fisheries, industry associations and peak bodies and commercial fishing licence holders were used to support the findings of the preliminary and detailed assessment of fisheries activities and, ultimately, determine relevant persons which may potentially be impacted by the Otway Basin 3D MC MSS.

Full records of TGS's consultation process to date with commercial fishers is provided in the consultation records listed in **Appendix H**, with the assessment of merit provided in **Appendix K**.

TGS consider that the information provided to licence holders was sufficient to make an assessment of the proposed Otway Basin 3D MC MSS on their activities and should they have concerns, opportunities were provided for the licence holders to undertake further consultation so that TGS could provide any further information they needed or discuss any concerns.

TGS has and will continue to provide commercial fishing industry representatives with shapefiles and a Microsoft Excel spreadsheet containing the GPS coordinates of the OA that would allow fishers to copy and paste directly into their chart plotting computer systems so that they have a better idea on where the operations will occur in relation to their fishing areas.

5.5.7 Specific Relevant Persons Consultation – Traditional Owner Groups

First Nations or Traditional Owner people's values are described in **Section 4.6.1**. As described, Traditional Owner groups occupying coastal and near shore (including island) areas of NSW, South Australia, TAS, and VIC identify Sea Country as a central value for First Nations people. Although Sea Country cannot be physically defined, discussions with First Nations people suggest it encompasses both tangible and intangible values present in coastal areas across estuaries, beaches, bays, and offshore marine habitats, thus Sea Country values and sensitivities may include:

- Marine and avian species that hold significant and deep connections to lore and spiritual values;
- Cultural harvesting (historic and contemporary) of marine flora and fauna; and
- Sea and landscape features that hold significance spiritual values (such as dreamtime and creation values).

Traditional Owner groups that were identified as relevant persons were identified in general accordance with the process outlined in **Section 5.4**. Database searches via the National Native Title Tribunal Register[9] were conducted, as well as searches using the state based Aboriginal Heritage sites (where possible), as well as information sourced from the Australian Institute of Aboriginal and Torres Strait Islander Studies[10] and the Office of the Registrar of Indigenous Corporations[11]. Further searches were then conducted on individual Prescribed Bodies Corporates, Registered Aboriginal Parties, Native Title Holders, and individual Traditional Owner groups using keyword searches on the internet and social media pages that relate to traditional owner names, location and interest or function, etc. These search efforts focussed on coastal groups within VIC, NSW, South Australia and TAS that overlapped or were within close proximity to the EMBA, acknowledging that Sea Country could extend to the EMBA from locations outside and adjacent to the EMBA.

TGS identified 34 relevant persons as a Traditional Owner group and these relevant persons encompass a wide variety of organisations including land councils, Prescribed Bodies Corporates, Registered Aboriginal Parties, Native Title Holders, organisations that offer Traditional Owner groups legal support and groups that represent individual Traditional Owner people.

TGS initially contacted Traditional Owner groups via email or phone providing introductory information about the survey, via email including the information sheet. TGS would then offer either an in-person or online meeting to ascertain the most appropriate method for consulting their people going forward and the response varied depending on each relevant person's level of interest or function. Again, as with other relevant person groups, further information was provided on a case-by-case basis and was tailored to their individual requirements.

[9] http://www.nntt.gov.au/searchRegApps/NativeTitleRegisters/Pages/Search-National-Native-Title-Register.aspx
[10] Australian Institute of Aboriginal and Torres Strait Islander Studies (aiatsis.gov.au)
[11] Office of Registrar of Indigenous Corporations | Office of the Registrar of Indigenous Corporations (oric.gov.au)

A lot of the relevant persons particularly within NSW, South Australia and parts of TAS could not understand why TGS was contacting them, given the proximity of the OA to their location. However, TGS explained the EMBA and regulatory requirement to consult with all relevant persons.

Following initial communications with identified Traditional Owners groups were also asked if they wished to or were able to identify TGS of other potentially relevant persons who may also which to be consulted. In the event of new Traditional Owners being identified, they were contacted by TGS to ensure that they were made aware of the EP development, provided with the relevant information, and included into the continuing consultation process on a case-by-case basis.

Following consultation with Traditional Owner representatives and feedback provided, a more specific information sheet for Traditional Owner groups was developed, which was focused on the details of the Otway Basin 3D MC MSS and the control measures in place addressing their queries and concerns noted in previous meetings.

TGS will continue consultation with all Traditional Owner groups within their consultation register (or newly added groups) throughout the duration of the EP development process, and for the duration of the implementation of the Otway Basin 3D MC MSS itself, unless requested otherwise by the Traditional Owner group, for example to be removed from the consultation program.

The full records of all Traditional Owner groups consulted with to date are included in the consultation log provided in **Appendix H**. Where applicable, the assessment of merit of any objections or claims identified in the consultation process are also provided, along with the full record of all consultation processes (emails, telephone calls, meetings) included in **Appendix K**.

5.5.8 Specific Relevant Persons Consultation – Environmental Groups

Given the location and proximity of the Otway Basin 3D MC MSS to the significant environmental values and sensitivities identified in **Section 4**, TGS determined it was essential to engage with environmental groups that may have a function, interest or activity impacted by the Otway Basin 3D MC MSS. Similar to Traditional owner groups, environmental groups that were identified as relevant persons were identified in general accordance with the process outlined in **Section 5.4**. This included keyword searches on the internet and social media for any environmental groups that are present within the general vicinity of the EMBA with particular focus on coastal and marine areas in VIC and TAS, or those groups that have a national function or concern across Australia (e.g. Australian Conservation Foundation), or globally (International Fund for Animal Welfare). At the time of submission, TGS is corresponding with 19 environmental groups.

Following initial communications with identified environmental groups were also asked if they wished to or were able to identify TGS of other potentially relevant persons who may also which to be consulted. In the event of new environmental groups being identified, they were contacted by TGS to ensure that they were made aware of the EP development, provided with the relevant information, and included into the continuing consultation process on a case-by-case basis.

TGS will continue consultation with all environmental groups within their consultation register (or newly added groups) throughout the duration of the EP development process, and for the duration of the implementation of the Otway Basin 3D MC MSS itself, unless requested otherwise by the environmental group, for example to be removed from the consultation program.

The full records of all environmental groups consulted with to date are included in the consultation log provided in **Appendix H**. Where applicable, the assessment of merit of any objections or claims identified in the consultation process are also provided, along with the full record of all consultation processes (emails, telephone calls, meetings) included in **Appendix K**.

5.5.9 Management of Objections and Claims

Any objections or claims raised during consultation, including during continuing consultation, are substantiated utilising publicly available information, including scientific literature and/or fishing data where available. Where an objection or claim is substantiated, it will be assessed as per the risk assessment process outlined within **Section 6** and, depending on the outcome of this assessment, appropriate controls will be applied to manage the impacts and risks to **ALARP** and an **Acceptable Level**. Further to this, if the objection or claim triggers a revision of the EP, this will be managed in accordance with the Management of Change process outlined within **Section 10.4.6**. TGS will advise the relevant person that raised the objection or claim of the outcome of this process, including whether or not the objection or claim is substantiated, how it was assessed and what, if any, controls were put in place to manage the impact or risk to **ALARP** and an **Acceptable Level**.

A number of responses have been received from relevant persons since the consultation programme has commenced. The nature of responses was varied; some included requests for further information about the survey equipment or operations, or to be kept informed and some noted that the proposed survey was not relevant for their interest in the area. Where objections or claims were received, these were addressed as per the discussion above, with details on how these were addressed within the EP being outlined within **Appendix I**. These claims were considered to be adequately addressed through the development of this EP and associated control measures and operational procedures.

Some objections and claims were outside of the scope of the EP and the proposed activity, particularly relating to the general opposition to the extraction and drilling of fossil fuels. When such a submission is received, TGS advises the relevant person they acknowledge and note their comments and will continue consultation to keep them updated with the survey progress.

Likewise, in accordance with the Environment Regulations 16(b)(ii) all objections and claims that TGS has received until **16 June 2023** have been considered in the assessment of risk and responses and within the development of this EP and control measures, which have been tailored where necessary to reduce the risks to **ALARP** and an **Acceptable Level**. The 16 June 2023 was selected as an arbitrary date to assist with preparing this EP for submission. TGS acknowledges that consultation with all relevant persons within the TGS consultation program is continuing consultation for the completion of this EP and likely to continue for many of the relevant persons throughout the duration of the EP.

The control measures in **Section 7** and **Section 8** that will be implemented throughout the Otway Basin 3D MC MSS are considered adequate to reduce impacts of the Otway Basin 3D MC MSS, and in particular the protection of the BIAs and their corresponding receptors to **ALARP** and an **Acceptable Level**. Where existing control measures did not adequately address any objections or claims made, additional control measures were identified and implemented.

In accordance with the Environment Regulations 16(b)(iii), the claims that have been made by relevant persons are summarised in **Appendix M**, with the response by TGS and the relevant section within the EP where those concerns are addressed. The full correspondence between the relevant persons and TGS is provided in **Appendix H**.

5.5.9.1 Self-Identification of Relevant Persons

[TBC following 30-day public notification period]

5.5.10 Assessment of Provision of Sufficient Information and Time to Respond

Regulation 11A(2) of the Environment Regulations states that:

> *"For the purpose of the consultation, the titleholder must give each relevant person sufficient information to allow the relevant person to make an informed assessment of the possible consequences of the activity on the functions, interests or activities of the relevant person."*

As detailed within **Section 5.5.3** the initial consultation included the provision of an information sheet to all relevant persons; consisting of an information sheet and a detailed email. This information sheet outlines various aspects of the Otway Basin 3D MC MSS including the location of the OA, a description of the proposed seismic activity, approximate timing and duration, vessels and equipment and the adherence of TGS to the relevant legislation. In addition, where further information was requested by a relevant person, this has been provided on a case-by-case basis.

Given the bespoke nature of the consultation methodology, and that TGS has provided the full scope of the Otway Basin 3D MC MSS and any additional information upon request on a case-by-case basis, it is considered that the information provided has been sufficient for the relevant persons to make an informed decision on whether their activities would potentially be impacted by the Otway Basin 3D MC MSS. This process also made available the opportunity for relevant persons to provide feedback, raise concerns, participate in further consultation, and submit any objections to TGS.

An assessment of sufficient time and reasonable periods is described in **Section 5.5.1.** It is re-iterated, given the iterative consultation process, and that where further information and consultation has been requested, this is subsequently accommodated for in extending the period required for consultation. In all cases, where further information was requested, it has been provided where possible. Some very specific requests have been particularly challenging due to timing and development of the EP. New information provided by relevant persons or discovered during research meant the EP is frequently being updated and therefore information distributed to relevant persons outdated. When communicating with relevant persons in this situation, TGS expressed their preference to provide certain information once the EP had been finalised and released for review.

To ensure TGS had provided sufficient information, they would ask all relevant persons during the on-line and in-person meetings, whether there were any further queries before closing the meeting and would always extend an offer at the meeting to contact TGS if the relevant person required additional information. TGS would also offer to provide additional information to their relevant persons within most email correspondence.

All relevant persons currently within the consultation register are considered 'active' and consultation with them will continue for the duration of and following the Otway Basin 3D MC MSS until required. Engaging with these organisations provided TGS with a greater understanding of the potential impacts the Otway Basin 3D MC MSS may have on the licence holders and their activities. TGS has also increased its effort for relevant persons that did not respond, to identify alternative contact details or contact methods in case the contact details were no longer valid. All relevant persons that TGS has not received a response from will remain in the consultation program as with those persons who have responded and receive updates throughout the duration of the EP.

Based on the discussion and information provided above, TGS considers that the information provided to the relevant persons during the consultation process has been sufficient and that relevant persons have had sufficient time to consider the information and make an informed decision as to any potential impacts of the survey on their activities, in accordance with the Environment Regulations and relevant guidance.

5.5.11 Fulfilment of Consultation Obligations

As outlined within the Guidance Document, the obligation to consult must be discharged prior to submitting an EP to NOPSEMA. In order for the consultation to be considered fulfilled, the following matters need to be addressed:

- The provision of sufficient information as per **Section 5.5.1.3**;
- A reasonable period of time to make an informed decision must have been demonstrated as per **Section 5.5.1.4**; and
- If any objections and claims are raised during consultation, it is a requirement that these are adequately assessed and addressed, where valid, as per the discussion within **Section 5.5.9.**

An assessment of whether consultation with each relevant person has been fulfilled is included within the Relevant Person Consultation Report within **Appendix I**.

One of the main aspects of this assessment is in relation to the response(s) that were received from the relevant persons. As an example of this assessment, where a relevant person has not responded to consultation (with the provision of sufficient information), and a reasonable period of time has elapsed, then this consultation would be considered fulfilled but continues in order to receive updates on the project.

It is worth noting that although the fulfilment of consultation with relevant persons is a key aspect of the EP process, TGS will continue to undertake consultation with relevant persons in an ongoing manner as outlined within **Section 5.5.9**.

5.5.12 Continuing General Relevant Person Consultation

TGS will continue to engage with all relevant persons for the duration of the Otway Basin 3D MC MSS, in accordance with the Environment Regulations 14(9), to provide project updates and keep them informed as information becomes available. To achieve this, TGS set the following objective with regard to continuing consultation, as part of the relevant person consultation programme (see **Section 5.2**), that being 'support ongoing relevant person identification and consultation throughout the project'.

The objective was underpinned by the following outcomes, each of which were considered necessary for successful continuing consultation:

- Continual identification of relevant persons that may be affected by the Otway Basin 3D MC MSS;
- Provision of sufficient information to all relevant persons identified; and
- Continual identification and resolving of any issues that may arise as identified by relevant persons.

Continuing consultation, as described in the relevant objectives and outcomes above, will be achieved by implementing the following actions:

- At least six weeks prior to survey commencement, TGS will perform a desktop review to assess for any new relevant persons in the region. This assessment will include all relevant EP submissions and a review of relevant persons identified by other proponents of seismic operations in any newly accepted EPs;
- In the event that a new relevant person is identified by TGS, they will be contacted as soon as possible to provide them with sufficient information regarding the Otway Basin 3D MC MSS. This will include a description of the identified impacts and associated control measures that are being implemented so that it is clear to see that the risks to this particular relevant person will be reduced to **ALARP** and **Acceptable Levels**; and
- TGS will distribute information sheets at selected locations that target recreational users who are transient to the OA. For example, at retailers that sell recreational fishing gear and local dive shops.

Where the above actions have not resulted in successful notification to relevant persons and there are relevant persons out within the OA, TGS will lean on one Support Vessel and one Chase Vessel on the water during the Otway Basin 3D MC MSS. These vessels will be in contact with other maritime users during the survey and will be able to identify any vessels on the water that are unaware of the survey operations and ensure that no vessels travel in close proximity to the Seismic Vessel or streamers towed behind the vessel.

In addition to this more generalised continuing consultation process with relevant persons, some relevant persons will be consulted with in an ongoing manner where some of the matters raised during the initial consultation are complex in nature and often in relation to activities outside the scope of this EP, or these discussions involve establishing an ongoing relationship with the relevant person(s).

Should any relevant person raise any objections or claims or provide feedback during this continuing consultation that has not previously been considered within the development of the EP, these will be managed as per **Section 5.5.9**.

The following decision support resources would be applied to assess whether any potential change in impacts or risks was significant:

- Classifications of existing impacts and risks within the risk assessment matrix in this EP;
- Legislative requirements, guidelines, standards;
- Relevant literature;
- UAM results;
- Sound thresholds within the EPBC Act;
- The Temporary Threshold Shift (**TTS**) and Permanent Threshold Shift (**PTS**) for the relevant receptors identified within the OA (**Section 7.2**); and
- Professional Judgement.

5.5.13 Pre-activity Notification to Relevant Persons

Prior to commencing the Otway Basin 3D MC MSS, TGS will provide specific details to all relevant persons in relation to confirmed project timing and location. A number of temporal and spatial driven mitigations have been implemented into the survey planning to reduce the impacts on blue whales within the BIA to **ALARP** and an **Acceptable Level**.

TGS has also committed to providing relevant persons with 48-hour look-ahead of where the survey vessels will be, so that they can then incorporate the survey plans into their operations. This look-ahead will be updated every 24 hours.

Navigational warnings and Notice to Mariners will also be issued on maritime radio and via email correspondence which provide information about the Seismic Vessel, including the Seismic Vessel being restricted in its ability to manoeuvre due to towing the streamer array.

A summary of the pre-activity notification process by TGS is provided in **Table 42**.

Table 42 Pre-Activity Notifications by TGS

Timing – prior to the Seismic Survey	Stakeholder	Information to be Provided
Approval of EP	DNP	That the EP has been approved by NOPSEMA via email to MarineParks@environment.gov.au
4 weeks	All relevant persons identified	• Summary of proposed activity • Summary of vessel and seismic gear • OA coordinates • Date of activity commencement • Duration of activity • TGS contact details
4 weeks	Australian Defence Force	• Operational area coordinates • Date of activity commencement
4 weeks	AHO	Contact AHO at datacentre@hydro.gov.au with details relevant to the operations to promulgate the appropriate Notice to Mariners. Updates will be provided to AHO on progress and, importantly, any changes to the operations.
10 days prior	NOPSEMA	Written notification of the date of intention to commence the Seismic Survey that is included within this EP.

Timing – prior to the Seismic Survey	**Stakeholder**	**Information to be Provided**
At least 24-48 hours prior to operations	AMSA's Joint Rescue Coordination Centre (**JRCC**)	Contact JRCC by email (rccaus@amsa.gov.au) for promulgation of radio-navigation warnings. The JRCC requires: • Vessel details (including name, callsign and Maritime Mobile Service Identity) • Satellite communication details (including INMARSAT-C and satellite telephone numbers) • Area of operation • Requested clearance from other vessels • Date of activity commencement • Duration of activity • TGS contact details • Any other information that may contribute to safety at sea Updates should be provided to JRCC on progress and, importantly, any changes to the operations.

5.5.14 Post-activity Notification to Relevant Persons

There are also some post-survey notification requirements that TGS are required to adhere to. These are provided in **Table 43**.

Table 43 Post-Activity Notification Requirements

Timing – post **Seismic Survey**	Stakeholder	Information to be Provided
Relevant time post-completion	All relevant persons	Notification that the survey is now complete, and the survey vessels are no longer in the area.
Relevant time post completion	AMSA	Summary of any significant or noteworthy interaction with commercial shipping during the Otway Basin 3D MC MSS.
10 days post completion	DMIRS	Provide a cessation notification to petroleum.environment@dmirs.wa.gov.au. Consultation with DMIRS resulted in this request, and although no timeframe was provided, a 10-day notification period has been utilised to align with NOPSEMA notification.
10 days post completion	NOPSEMA	Written notification to NOPSEMA advising of the completion of the survey.
As soon as practicable	NOPSEMA	Written notification to NOPSEMA advising that all of the activities and obligations covered under the EP have been completed.

5.6 Public Comment

NOPSEMA will publish TGS' EP on their website in accordance with the Environment regulations 9(AB) and 11B for a period of 30 days. It will be notified that the EP will be available for public comment on NOPSEMAs website by the following means: TGS's website, a national newspaper (The Australian – National Daily), state-wide newspapers (TBC) and regional newspapers close to the OA (TBC).

Any submissions received during this 30-day public notification period will be treated in accordance with the relevant persons consultation programme as outlined in **Section 5.5**. In accordance with the framework, all merits of the submissions will be assessed according to the functions, activities and interests of the relevant persons, the merits assessed, and if required, be subject to the continuous consultation programme following the 30-day consultation period. Where applicable and as required following the continuing consultation process, any relevant persons identified during the 30-day period will have the same opportunity to be fully informed through the entire Otway Basin 3D MC MSS programme (i.e. 48 hour look-aheads), as well as providing all the pre-survey notifications prior to survey commencement.

5.7 Fuel Oil Spill Response Emergency Consultation Protocols

This section sets out the process TGS will follow in the event of an unplanned release of fuel oil to the marine receiving environment. There are two key components to the process: the role of the OPEP, and the communication with relevant persons. This section identifies the relationship between the two processes.

5.7.1 Oil Spill Emergency Plan

Section 10.10 sets out the OPEP – TGS's arrangements for responding to a fuel oil spill (Level 1 or Level 2) event during the Otway Basin 3D MC MSS. The OPEP follows the framework and requirements set out in the National Plan for oil spill event response.

Table 147 lists the division of responsibilities between statutory authorities and the nominated Control Agency (**CA**) for a Level 1 or 2 spill. The role of the CA is to assume control, including decision making ability, to respond to any oil spill incident and respond in accordance with the National Plan.

Under the OPEP, notification processes are the responsibility of the Vessel Master. **Table 148** sets out the OPEP notification process and timeframes for both Level 1 and Level 2 responses. This includes responsible authority direct numbers, and key instruction for notification.

On this basis, the focus of the OPEP is on the CA's decision-making process, as guided by the National Plan to implement notification processes, instigate the Net Environmental Benefit Analysis (**NEBA**), and to instigate decisions as to the appropriate course of action (including response logistics, liaison with TGS's Project Manager to instigate the Operational and Scientific Monitoring Plan (**OSMP**)) under a Level 1 or Level 2 spill event.

5.7.2 Relationship of OPEP to Relevant Persons

Relevant person(s) are not formally included in the notification process described in **Section 10.10.6.3**. The roles of the agencies/personnel, under the direction of the CA, are focussed on the containment of the spill, and immediate (within hours to 48 h) need to provide information and updates of any event to Statutory Agencies (**Table 148**). The full list of relevant persons is provided within **Appendix G**.

Although relevant person(s) formally sit outside the OPEP Notifications process, in the event of a fuel oil spill, relevant persons will need to be notified to ensure they have timely and sufficient information to carry out their functions, inform their own stakeholder groups, manage their own decision making processes, and manage their (and their stakeholders) own risks accordingly. Procedures are in place with industry body relevant persons on an as needs basis, that should a fuel oil spill release occur, TGS will notify affected industry bodies immediately and those bodies will inform all licence holders that could potentially be impacted by a fuel oil spill. TGS would still undertake its own notifications, but the agreement with industry bodies will specifically target the licence holders that use the area identified in the wider EMBA.

The notification and emergency consultation with relevant persons, in the event of an oil spill, recognises:

- Emergency notification is undertaken in good faith and with transparent, accurate and timely information;
- Relevant persons may hold different values and interests in the affected area of the unplanned event; TGS are not making decisions or judgments about the values of the relevant persons and what may be of importance for managing actual or perceived risk management of the relevant person(s); and
- Relevant persons are best placed to inform TGS and the CA about the impact of the spill on their particular interest; information of specific interests, values and sensitivities of relevant persons can be incorporated into the NEBA where possible, which may be used to inform the logistical response process and requirements of any OSMP. The list of relevant persons that have been consulted with are included in **Appendix G**.

It is important to note for the Emergency response process, CA may also be relevant persons (depending on the jurisdiction, and where the governmental agency has an interest/value in the affected area), but relevant persons are not automatically a CA.

5.7.3 Consultation with Relevant Persons

The following section describes the general consultation process with relevant persons that will be followed in the event of a Level 1 or Level 2 spill, shown schematically in **Figure 71**. It is intended that this process is strongly aligned with the OPEP (**Section 10.10**) as well as the OSMP (**Appendix L**) and is aimed at meeting the information requirements for any relevant persons requesting notifications for a Level 1 or Level 2 spill.

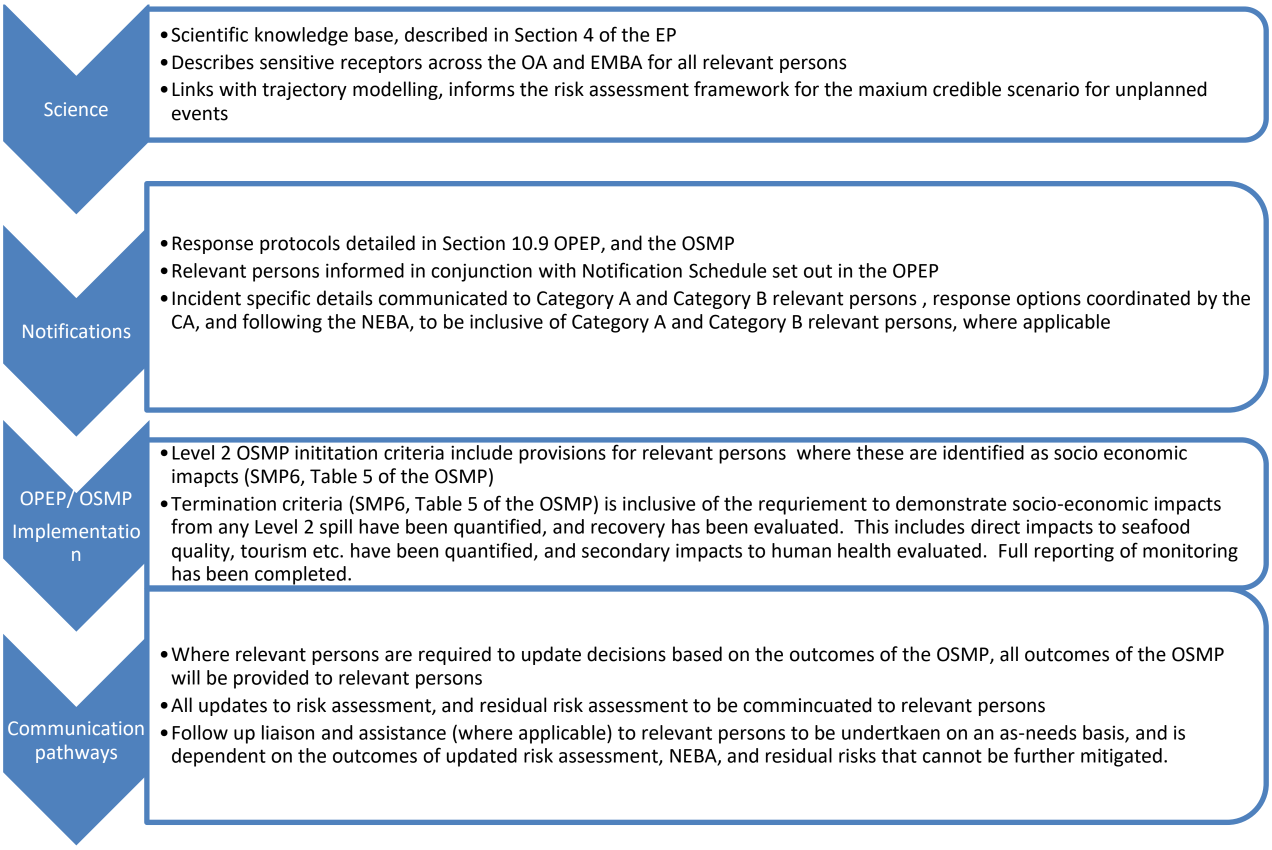

Figure 71 Information Pathways for Informing Relevant Persons under Level 1 or Level 2 Spill Scenarios

5.7.3.1 Scientific Knowledge Base

Fundamental to understanding actual or perceived risks to sensitive receptors is a solid understanding of the aquatic biota and marine receiving environment in the vicinity of the Otway Basin 3D MC MSS. The current state of scientific knowledge as it relates to aquatic biota and marine receptors within the OA and EMBA are detailed in **Section 4**. This knowledge directly serves to inform the NEBA (**Section 10.10.5**) under any real time trajectory modelling, in the unlikely event of a Level 2 Spill assessment.

Combined with the assessment of risks (**Section 8.4**), updates to actual or perceived risks to sensitive receptors can be benchmarked against the current state of knowledge.

5.7.3.2 Notifications

Section 10.10.6.3 sets out the notifications process to be adhered to in the event of a Level 1 or 2 Spill. Accordingly, Category A and Category B relevant persons, as identified by the location and nature of the spill, will be notified in conjunction with the statutory agencies as per the schedule in **Table 148**.

TGS are not in the position to impose decision making processes onto any relevant persons but will ensure that relevant persons are provided with the most up to date and relevant scientific knowledge so that relevant persons are in the position to develop fully informed decisions to manage their interest in the affected area. For example, decisions to close fisheries, or restrict contact recreation, fall outside the expertise and commercial knowledge of TGS, but TGS will ensure all up to date science-based information is communicated to affected relevant persons so that they are in a position to coordinate managed responses, including the management of actual or perceived risks to their own stakeholder groups.

5.7.3.3 OPEP/OSMP Initiation and Implementation

Initiation of logistic response actions from a Level 1 or Level 2 spill are the responsibility of the CA. For a Level 2 spill, the response process follows the implementation process set out in **Figure 3** of the OSMP. This process indicates the NEBA is undertaken early in the response, as well as following the monitoring and reporting requirements to ensure any spill is remedied and effects are mitigated.

The OSMP describes Type 1 and Type 2 (Scientific) criteria for both the initiation and termination of monitoring. Provision of socio-economic impact monitoring (inclusive of affected relevant persons) is included as key criteria for any scientific monitoring programme. The process of OSMP initiation and termination also serves to inform the NEBA to ensure the appropriate course of response is being implemented, and to ensure all affected relevant persons are provided with sufficient and timely scientific knowledge to manage stakeholder risks (actual and perceived).

5.7.3.4 Communication pathways

All outcomes of the OPEP and OSMP will be communicated to affected relevant persons where decisions are required to inform any updated actions the relevant person have been required to undertake due to any Level 1 or 2 spill event during the Otway Basin 3D MC MSS. Given the OSMP is specific to initiation criteria (see **Table 5** of the OSMP, **Appendix O**), and decisions pending the CA and updated NEBA, specific timeframes for communication processes to relevant persons cannot be defined at this stage. In the event of a Level 2 spill, and any OSMP implementation, communication/consultation with relevant persons (concerned with socio-economic impacts) is also included as part of the initiation criteria (see SMP6, **Table 5** of the OSMP, **Appendix O**).

Information provided may include:

- Outcomes of secondary NEBA, with focus on any sensitive receptors specific to affected relevant persons if required;
- Updated risk assessments undertaken for sensitive receptors, informed by real time trajectory modelling and updated information about the spill characteristics; and
- Updated knowledge about any potential residual risks to sensitive receptors, following the implementation of mitigations and actions as directed by the CA during the implementation of the OPEP and OSMP response.

In the event that residual risks to sensitive receptors are unacceptable to affected relevant persons, TGS will seek to engage to fully understand and assist where applicable the extent to which further actions under the OSMP and NEBA can be beneficial.

For Commercial Fishers, TGS has agreed to financially support the commercial fishing industry (as represented by peak industry bodies SETFIA, VFA and TSIC) in the unlikely event of an unplanned spill impacting the industry as per the TGS Loss Adjustment Protocol. TGS will consider any claims for compensation from licence holders on a case-by-case basis, and may be provided in the following circumstances:

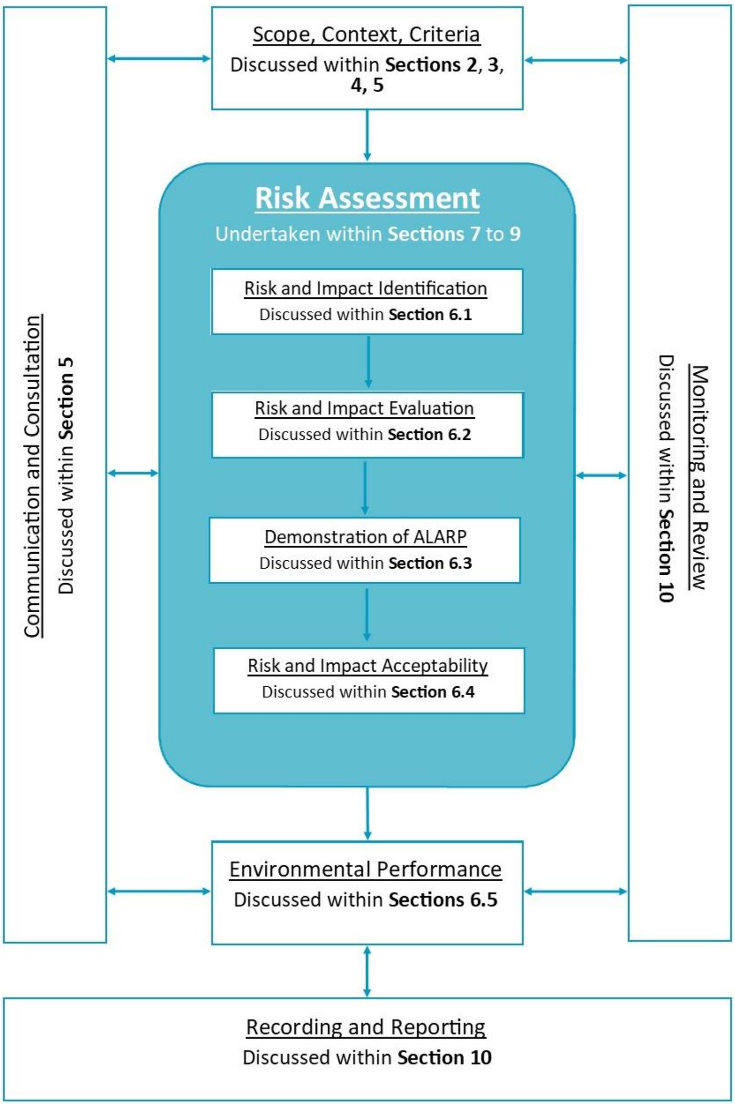
- Fishing equipment has been damaged as a direct result of a fuel oil spill from the Otway Basin 3D MC MSS; and
- A licence holder experiences a reduction in historical average Catch Per Unit of Effort as a result from either perceived or actual impacts associated with a fuel oil spill from the Otway Basin 3D MC MSS.

In order to receive compensation, a licence holder must be able to show that they would have received the revenue from the landed catch that is subject to the claim, incurred additional costs associated with perceived or actual impacts, or have incurred costs from lost or damaged fishing equipment.

6 Environmental Impact and Risk Assessment Methodology

Regulation 13(5) and 13(6) of the Environment Regulations requires TGS to include details of all environmental impacts and risks arising from or associated with the proposed activity, along with an evaluation of these impacts and risks. The assessment should give appropriate consideration to the nature and scale of each impact or risk, and whether these are likely to be realised as a result of planned and unplanned operations. Accordingly, this assessment must detail the control measures which will be utilised to reduce the impacts and risks of the activity to **ALARP** and an **Acceptable Level**.

The following impact and risk assessment methodology has utilised the joint Australian & New Zealand International Standard Risk Management – Guidelines, (**AS/NZS ISO 31000:2018**) (ISO, 2018). **Figure 72** shows a modified version of the AS/NZS ISO 31000:2018 risk management process diagram to provide a summary on the framework adopted in the development of this EP. To this end, the corresponding sections which address each aspect of the risk management process have also been highlighted.



Source: modified from ISO, 2018

Figure 72 Risk Management Process Adopted from AS/NZS ISO 31000:2018

Some useful definitions for terms which are used throughout the environmental impact and risk assessment are provided in **Table 44**. These terms have been adapted from AS/NZS ISO 31000:2018 and associated Handbook on Environmental Risk Management – Principles and Process (HB 203:2006) (Standards Australia, 2006).

Table 44 Environmental Impact and Risk Assessment Terminology

Term	Synonymous Terms	Description
The activity		An activity or activities which may occur as part of the Otway Basin 3D MC MSS.
Acceptable Level[1]	Acceptable Impact	An 'acceptable level' is the specified amount of environmental impact and risk that an activity may have which is tolerable, is consistent with all relevant principles, and does not compromise the management/conservation/protection objectives of the environment.
As Low as Reasonably Practicable[2]		The operator must show through reasoned and supported arguments that there are no other practicable options that could reasonably be adopted to further reduce risks. Practicable does not mean 'possible' – a decision on whether an option is practicable involves consideration of several factors, including the sensitivity of receiving environment to adverse effects; the financial implications of the option when compared with other options; and the current state of technical knowledge and the likelihood that the option can be successfully applied.
Control Measure[3]		A system, an item of equipment, a person, or a procedure, that is used as a basis for managing environmental impacts and risks. Control measures maintain and/or modify risk
Cost[4]	Sacrifice	The sacrifice required for implementing a control measure, which includes an impost such as the money, time, and/or trouble required to implement a particular control measure. Environmental cost may also be a cost in some circumstances (e.g. dispersant use on an oil spill).
Consequence[1,4,5]		Magnitude/level of effect on the environment in the event that an adverse effect occurs as a result of an activity or incident. For example, loss, injury, or concern. This may be expressed qualitatively or quantitatively.
Effectiveness (*re control measures*)[1]		A measure of how well the control performs the required function and is determined with consideration to aspects of reliability, functionality, survivability, and availability
Environmental Performance Outcome[1]		A specified measurable level of environmental performance that titleholders are seeking to achieve for the life of the activity, and which supports effective management of aspects of an activity to the extent that any associated environmental impacts and/or risks are of an Acceptable Level.
Environmental Performance Standard[1,3]		Parameters which control measures are assessed against to ensure they consistently perform to reduce the impact or risk to ALARP and to an Acceptable Level.
Practicability (*re control measures)*[1]		Practicability is a measure of the risk reduction (benefit) gained from applying the control measure compared to the cost.
Predicted Impact[1,7]	Impact	Actual or potential change to the environment, adverse or beneficial, that is predicted to occur by a proposed activity.

Term	Synonymous Terms	Description
Acceptable Impact[1]	Acceptable Level	An 'acceptable level' is the specified amount of environmental impact and risk that an activity may have which is tolerable, is consistent with all relevant principles, and does not compromise the management/conservation/protection objectives of the environment.
Incident[4]	Event	Any occurrence that can have an adverse impact on the environment. An incident releases the intrinsic potential of a hazard.
Inherent Risk[4]		The untreated risk level.
Likelihood[5]	Probability	The probability that something (e.g. an adverse effect) will occur as a result of an activity. This may be expressed qualitatively or quantitatively.
Measurement Criteria[1]		Define how the environmental performance outcomes and standards will be measured to determine whether the outcomes have been met during the Otway Basin 3D MC MSS.
Receptor[1,4]		A physical, biological, chemical, or social component of the environment which may be subject to an impact.
Risk[4,5]		The chance of something happening that will have an impact on the objectives. It is measured in terms of the consequence should an adverse effect occur and its likelihood of occurring.
Residual Risk[7]		The risk remaining when control measures are in place.
Source of Impact[4]	Stressor Hazard Environmental aspect	An activity or entity that induces an adverse response or impact.

6.1 Identification of Environmental Impacts or Risks

Regulation 13(5)(a) of the Environment Regulations requires an EP to include details of the environmental impacts and risks which may arise as a result of the activity, to establish a link between the proposed activity and the environment that may be affected. On this basis, parts of the activity that interact with the environment and, by extension, those relevant persons/marine users who may use it, were identified with consideration to the following:

- The legislative requirements, guidelines and standards that apply to the Otway Basin 3D MC MSS (**Section 2**);
- A comprehensive description of the activities that will occur during the Otway Basin 3D MC MSS, including timing, and the equipment to be utilised (**Section 3**);
- A comprehensive description of the existing environment that may be affected by the activity, including key sensitivities such as species distributions, subsea habitat, and the location of biologically important areas, protected areas and socio-economic activities which may coincide with the Otway Basin 3D MC MSS identified as part of the desktop studies (**Section 4**); and
- Feedback from relevant persons regarding the socio-economic activities which may coincide with the Otway Basin 3D MC MSS (**Section 5**).

The proposed Otway Basin 3D MC MSS activities have been split into two sub-categories: planned and unplanned activities. Planned activities are defined as those which constitute part of the MSSs approach and are known to occur, whereas unplanned activities are defined as those which have a risk of occurring but are not anticipated to be realised as part of normal operations. It is important to distinguish that planned activities can give rise to both known and potential environmental impacts, whereas unplanned activities can only be associated with potential environmental impacts. This is further described in **Section 6.2.**

The following activities have been considered within this assessment:

- Planned activities (**Section 7**), including:
- Physical presence of the Seismic Vessel and towed equipment (**Section 7.1**);
- Acoustic disturbance to the marine environment (**Section 7.2**);
- Routine permissible waste discharges (**Section 7.3**);
- Atmospheric emissions (**Section 7.4**); and
- Artificial light emissions (**Section 7.5**).
- Unplanned activities (**Section 8**), including:
- Establishment of invasive marine species (**Section 8**);
- Streamer loss (**Section 8.2**);
- Vessel collision or sinking, and its associated potential hydrocarbon spill (**Section 8.2**);
- Hydrocarbon spill response (**Section 8.4**); and
- Accidental release of hazardous and non-hazardous materials (**Section 8.5**).

In addition to the above sub-categories, the potential cumulative impacts and risks which may arise as a result of the Otway Basin 3D MC MSS have been considered within **Section 9**.

6.2 Evaluation of Known and Potential Environmental Impacts and Risks

In accordance with Regulation 13(5)(b) of the Environment Regulations, an EP must include an evaluation of all potential impacts and risks which may arise as a result of the proposed activity, appropriate to the nature and scale of each impact or risk. The purpose of this evaluation is to document the analysis undertaken to establish the environmental impacts and risks in terms of their extent, duration, severity, and certainty in order to demonstrate that the activity can be undertaken in such a way that the environmental impacts and risks will be managed to **ALARP** and an **Acceptable Level** (NOPSEMA, 2022).

To achieve this, the source of impact, pathway through which impacts may be realised and the potential receptors must first be defined. Receptors may include individuals, protected species, populations, habitats, ecosystem functions and socio-economic features or activities. This information forms the basis for which the relative consequence, likelihood and residual risks of impacts can be assessed, in broad accordance with the methods and principles described within the AS/NZS ISO 31000:2018 and HB 203:2006.

The evaluation of known and potential environmental impacts and risks is a systematic process comprising six broad steps. These are described **Table 45** and discussed further in the following sections.

Table 45 Summary of Impact and Risk Evaluation Steps

Section	Description
6.2.1	Assessment of Nature and Scale
6.2.2	Identification of Receptors
6.2.3	Identification of 'Good Practice' Control Measures
6.2.4	Determination of Consequence Rank
6.2.5	Determination of Likelihood Rank
6.2.6	Determination of Residual Risk

6.2.1 Assessment of Nature and Scale

When evaluating the potential impacts and risks which may arise as a result of the proposed activity, the nature and scale of each impact or risk is determined considering:

- The relative sensitivity of the receiving environmental and the resilience to change of the EMBA;
- The type and number of impact pathways;
- The timing, duration and frequency of the impact, with consideration to environmental and ecological seasonal sensitivities (e.g. migratory periods for EPBC Act protected fauna, or high activity periods for commercial fisheries);
- The spatial extent of impacts;
- The severity of impacts (e.g. individual effects, population-level effects, ecosystem effects);
- Potential cumulative impacts; and
- Any uncertainty in the above information.

6.2.2 Identification of Receptors

Based on the descriptions provided in **Section 2** to **Section 5**, the receptors which have been determined as relevant to the Otway Basin 3D MC MSS include:

- Marine environmental quality (water, sediment, air quality);
- Plankton;
- Benthic habitats (Banks, Shoals and Reef);
- Benthic invertebrates;
- Marine fauna;
- EPBC Act listed marine fauna;
- Marine protected areas and sensitive areas;
- Cultural and heritage values (i.e. Aboriginal, European, and marine heritage values);
- Commercial fisheries;
- Commercial shipping;
- Tourism and recreation;
- Divers (commercial and recreational);
- Petroleum exploration and production activities;
- Defence activities; and
- Research activities.

6.2.3 Identification of Legislated and 'Good Practice' Control Measures

In accordance with the Risk Related Decision Making Framework described in the Oil & Gas UK Guidelines on Risk Related Decision Making (Oil & Gas UK, 2014), 'Good Practice' is considered to be the recognised risk management processes and measures which are implemented to manage well-understood impacts and risks generated by an activity. For the purpose of this EP, both legislative requirements and control measures considered to be 'Good Practice' were identified based on the guidance outlined in **Section 2** and with consideration to the Australian IUCN Reserve Management Principles for Commonwealth Protected Areas, relevant Approved Conservation Advice and Recovery Plans, Management Plans and TGS' internal practices.

Where 'Good Practice' is reflected in Australian legislation or relevant Australian Government policies and guidance, these requirements will be applied. When identified in non-regulatory source material, relevant 'Good Practice' will be adopted when feasible and reasonably practicable to implement.

6.2.4 Determination of Consequence Rank

For each receptor predicted to be impacted by a planned or unplanned event, the consequence rank has been determined assuming the credible worst-case impact or risk which may arise if controls fail. The applicable consequence rank is then selected with consideration the scale and duration of effect as described in **Table 46**.

6.2.5 Determination of Likelihood Rank

For each receptor predicted to be impacted by a planned or unplanned event, the likelihood rank has been determined based on historical frequency of analogous events occurring within the industry. The applicable likelihood rank has been selected assuming effective implementation of ‘Good Practice’ control measures, using the criteria described in **Table 47**.

6.2.6 Determination of Residual Impact and Risk

The residual impact and risk assessment has been undertaken to determine the effect of ‘Good Practice’ control measures in mitigating the inherent risk levels, for each receptor predicted to be impacted by a planned and/or unplanned event. Accordingly, the residual impact and risk ranking reflects that risk or impact that remains when all adopted control measures are implemented. The residual impact and risk are determined using the matrix presented in **Table 48**. Corresponding descriptions for each impact and risk ranking, ranging from ‘Negligible’ to ‘Very High’, are provided in **Table 49.**

If the residual risk does not meet the requirements outlined in **Section 6.3** and **Section 6.4**, iterations of the assessment process continue until the residual impact and risk are reduced to an **Acceptable Level** and/or additional controls have been identified and/or rejected or accepted to demonstrate **ALARP**.

Table 46 Criteria for Assessing Potential Consequence Levels

Consequence level	Scale of Effect	Duration of Effect	Effect on Populations & Protected Species and Recovery Period	Effect on Socio-Economic Receptors	Effect on Habitat & Ecosystem Function
0 – Negligible	Highly localised effect (<1 km^2)	Short-term and intermittent/temporary	No predicted adverse effects to populations. Immediate recovery. No protected species impacted.	No disruptions to normal activities. No predicted effects on natural resources or local communities.	Undetectable, affecting <1% of original habitat area. Ecosystem function unaffected.
–1 – Minor	Localised effect (1 – 10 km^2)	Short-term, occurring frequently but ceases when activity ceases	No detectable adverse effect to populations. Rapid recovery would occur (weeks to months). Some individuals of protected species may be impacted.	Short term disruptions to normal activities (weeks to months). Possible minor adverse effects to natural resources and/or local communities.	Measurable but localised, affecting 1 – 5% of original habitat area. Minor changes to ecosystem function.
–2 – Moderate	Medium scale effect (10– - 20 km^2)	Medium-term but ceases when activity ceases	Detectable impacts to populations. Could affect seasonal recruitment but does not threaten long-term viability. Recovery probably measured in months to years. Some population level effects may become apparent for protected species.	Medium-term disruptions to normal activities (months). Moderate adverse effect to natural resource and/or local communities.	Potential impacts more widespread, affecting 5 – 20% of original habitat area. Moderate changes to ecosystem function.
–3 – Severe	Large scale effect (20 – 50 km^2)	Long-term but ceases when activity ceases	Impacts to populations are severe and may limit capacity for population increase. Recovery measured in multiple years. Population level impacts are detectable for protected species.	Long-term disruptions to normal activities (years). Severe adverse effect to natural resources and local communities.	Widespread impacts, affecting 20 – 60% of original habitat area. Severe changes to ecosystem function.
–4 – Major	Very large scale effect (50 – 100 km^2)	Long-term and continues after activity ceases	Long-term viability of populations is clearly affected. Local extinctions are a real possibility if activity continues. Recovery period of decades. Serious conservation concerns for protected species.	Extensive disruptions to normal activities (years to decades). Highly significant and major adverse effects to natural resources and potentially affecting national communities.	Activity may result in major changes to ecosystem or region, affecting 60 – 90% of original habitat area. Major changes to ecosystem function.
–5 – Catastrophic	Regional effect (>100 km^2)	Permanent	Local extinctions are expected in the short-term. Long-term recovery greater than decades and possibly never recovers. Very serious conservation concerns for protected species.	Very extensive disruptions to normal activities (decades). Catastrophic, widespread and potentially irreparable damage to natural resources. Massive negative and potentially irreversible effects on local and national communities, which may not be able to maintain pre-effect livelihood.	Activity will result in critical changes to ecosystem or region, affecting virtually all original habitat. Total collapse of ecosystem.

Table 47 Criteria for Assessing Likelihood of Consequence Occurring

Score/Level	Likelihood of exposure	Historical frequency
–1 – Remote	Highly unlikely but theoretically possible	Unheard of in the industry
–2 – Rare	May occur in exceptional circumstances	Has occurred once or twice in the industry
–3 – Unlikely	Uncommon, but has been known to occur elsewhere	Has occurred more than five times in the industry but not in the company
–4 – Possible	Occurred in a minority of similar studies or projects	Has occurred in the industry and in the company
–5 – Likely	Likely to occur and has generally occurred in similar projects	Has occurred once or twice in the company
–6 – Certain	Could be expected to occur more than once during project delivery	Has occurred frequently in the company

* Whereby 'likelihood' = the likelihood of a consequence occurring from the various activities

Table 48 Overall Residual Risk of Impacts Matrix

		Consequence Level					
		0 – Negligible	1 – Minor	2 – Moderate	3 – Severe	4 – Major	5 – Catastrophic
Likelihood of Consequence	1 – Remote	Negligible (0)	Low (1)	Low (2)	Low (3)	Low (4)	Low (5)
	2 – Rare	Negligible (0)	Low (2)	Low (4)	Moderate (6)	Moderate (8)	Moderate (10)
	3 – Unlikely	Negligible (0)	Low (3)	Moderate (6)	Moderate (9)	High (12)	High (15)
	4 – Possible	Negligible (0)	Low (4)	Moderate (8)	High (12)	High (16)	Very High (20)
	5 – Likely	Negligible (0)	Low (5)	Moderate (10)	High (15)	Very High (20)	Very High (25)
	6 – Certain	Negligible (0)	Moderate (6)	High (12)	Very High (18)	Very High (24)	Very High (30)

Table 49 Residual Risk Ranking and Impact Descriptions

Risk Ranking	Predicted Risk	Predicted Magnitude of Impact
Very High (18 – 30)	Very High Risk – Unacceptable for project to continue under existing circumstances. Requires immediate action. Works should not re-commence until the risk has been reduced to ALARP and an acceptable level. If it is not possible to reduce the risk, work has to remain prohibited.	Very high Impact – Unacceptable for project to continue under existing circumstances. Requires immediate action. Works should not re-commence until the predicted magnitude of impact has been reduced to ALARP and an acceptable level. If it is not possible to reduce the risk, work has to remain prohibited
High (12 – 16)	High Risk – The level of risk is not tolerable and additional control measures are required to reduce the impact/risk, where practicable, to ALARP and an acceptable level.	High Impact – The predicted magnitude of impact is not tolerable and additional control measures are required to reduce the impact/risk, where practicable, to ALARP and an acceptable level.
Moderate (6 – 10)	Moderate Risk – The level of risk is acceptable, providing all practicable controls have been implemented to reduce the impact/risk to ALARP. Requires continued tracking and recorded action plans.	Moderate Impact – The predicted magnitude of impact is acceptable, providing all practicable controls have been implemented to reduce the impact/risk to ALARP. Requires continued tracking and recorded action plans.
Low (1 – 5)	Low Risk – The level of risk is acceptable without further reduction measures being required. Control measures consistent with good industry practice have been applied or have been assumed in the design process. No further development of control measures is required if ALARP.	Low Impact – The predicted magnitude of impact is acceptable without further reduction measures being required. Control measures consistent with good industry practice have been applied or have been assumed in the design process. No further development of control measures is required if ALARP.
Negligible (0)	Negligible Risk – no intervention or further monitoring is required. No detectable environmental impact.	Negligible Impact – no intervention or further monitoring is required. No detectable environmental impact.

6.3 Demonstration of ALARP

In accordance with Regulation 10A(b) and 13(5)(c) of the Environment Regulations, the EP must demonstrate that the environmental impacts and risks of the activity will be reduced to **ALARP**. In practice, this means that all available and effective control measures must be implemented where the cost is not grossly disproportionate to the environmental benefit gained from implementing the control measure. Accordingly, risk treatment involves a cost benefit analysis of alternative, substitute and additional control measures that may further reduce impacts and risks which have not been demonstrated to be ALARP during the evaluation of environmental impacts or risk (**Section 6.2**).

Ideally, the adopted control measures should reduce the residual impact and risk to a Low (or lower) ranking; however, if the impact or risk remains at a higher ranking, it is further assessed to determine whether it has been reduced to **ALARP.**

A systematic approach to demonstration of ALARP has been developed based on the requirements outlined in NOPSEMA Guidance Note ALARP N-04300-GN01660166 A138249 and with consideration to the Risk Related Decision Making Framework described in the Oil & Gas UK Guidelines on Risk Related Decision Making (Oil & Gas UK, 2014).

The Risk Related Decision Making Framework provides for a continuum of 'decision contexts', which comprise a combination of influential factors and constraints within which the decision as to the risk or impact an activity generates is to be made. These factors are broadly summarised as informing a) the type of activity to be undertaken b) the risk and uncertainty and c) the influence of relevant persons. Once the decision context has been defined, the appropriate assessment techniques can be determined. The following assessment techniques may be used for different decision contexts to determine if the activity is being managed to ALARP:

- Good practice: Adherence with recognised guidelines, standards and control measures that are used to manage well-understood impacts and risks is demonstrated;
- Engineering (or Environmental) Impact and Risk assessment: Quantitative analysis is undertaken to increase understanding of the impacts/risks. This may include the application of a range of techniques such as underwater sound modelling or cost benefit analysis; and
- Precautionary approach: Uncertainty is counterbalanced through conservative assumptions which include the 'worst-case' scenario that can be realised. Accordingly, a control measure may be more likely to be adopted.

For the purpose of this assessment, and in accordance with the standard level of approach identified within the approved body of EPs, three 'decision contexts' have been adopted: Type A, B & C (**Figure 73**).

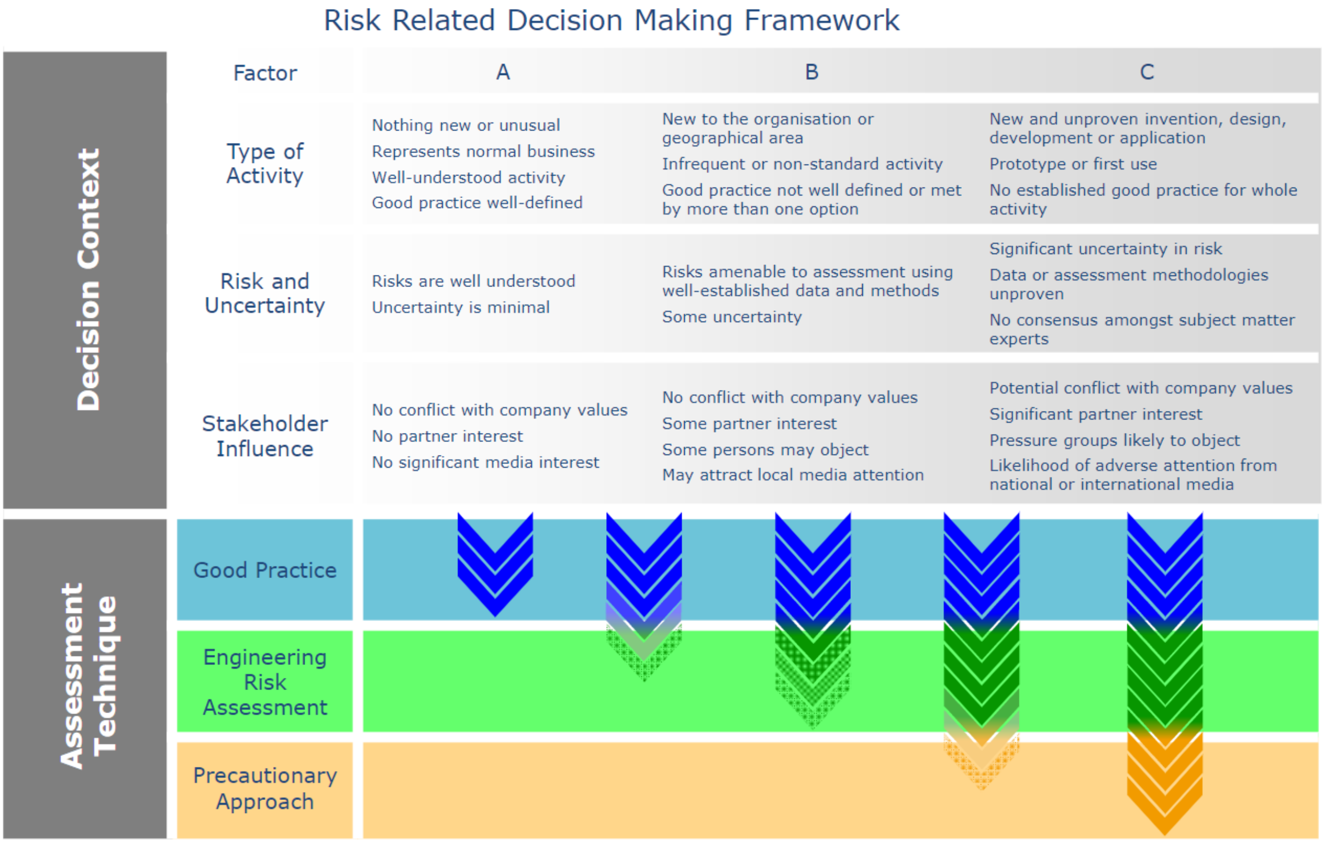

Figure 73 Risk Related Decision Making Framework, Oil & Gas UK (2014)

A description of each 'decision context' and the associated decision methodologies used to demonstrate achievement of ALARP is provided in **Section 6.3.1** to **Section 6.3.3.**

6.3.1 Type A

The decision context is determined to be Type A if the risks and impacts are relatively well understood, with minimal uncertainty and no considerable interest from relevant persons. In general, decision making will be guided by the application of recognised good practice which is well-defined in legislation, standards, and guidelines. Proactive and professional judgement, including utilising industry experience, are sufficient to identify effective control measures and assess adherence to legislative requirements and 'Good Practice'.

If the decision context is categorised as Type A, adherence to all relevant legislation, codes, and environmental standards and 'Good Practice' techniques and controls is considered sufficient to demonstrate the impacts and risks are managed to ALARP. Further assessment, such as an engineering risk assessment, is not necessarily required to identify additional control measures.

6.3.2 Type B

The decision context is determined to be Type B if the risks and impacts involve some uncertainty and greater complexity and generate several concerns from relevant persons. These risks may be novel to the proponent or area, attributed to a non-standard activity and, therefore, good practice is not necessarily well defined. They are typically associated with areas of increased environmental sensitivity.

If the risk is categorised as Type B, an Engineering (or Environmental) Impact and Risk Assessment is required. Additional quantitative analysis is performed, including through the use and interpretation of numerical analysis (e.g. analysis of commercial fisheries catch and effort data) or predictive modelling (e.g. UAM), to further define the risk or impact and cost benefit analysis for adopting further management. The cost benefit analysis is based on a weight of evidence approach to defining the possible environmental benefit gained from adopting alternate, substitute, and additional controls measures, compared to the cost of implementing them.

For the purpose of this EP, the hierarchy of controls, which follows a tiered system of 'eliminate-substitute-reduce-mitigate', has been utilised to identify alternate, substitute and additional controls measures (**Table 50**).

Table 50 General Hierarchy of Controls

Control	Example	Effectiveness
Eliminate	Elimination of the risk or impact, such as eliminating the light source to remove impacts from artificial light emissions.	Most Effective
Substitute	Substitute the method of an activity in favour of a lower impact one, such as substituting Heavy Fuel Oil for MDO to reduce the amount of atmospheric emission.	
Reduce	Reduction of the risk or impact, such as reducing the oil content in discharged water to reduce the potential contamination of the sea.	
Mitigate	Mitigate the potential risk or impact of conducting an activity, such as maintaining separation distances from land when discharging wastes to mitigate the potential impacts on coastal environments	Least Effective

The outcome of the cost benefit analysis determined whether a control measure was considered effective and/or practicable to implement. A clear justification is provided for each determination. Based on this determination, control measures were adopted for implementation or dismissed. ALARP is demonstrated when all available and effective control measures have been considered and implemented, where the cost is not grossly disproportionate to the environmental benefit gained from implementing the control measure.

6.3.3 Type C

The decision context is determined to be Type C if the risks and impacts involve sufficient complexity, uncertainty, and interest from relevant persons to warrant a precautionary approach. The activity may be previously untested, and therefore lack consensus amongst subject matter experts or associated proven risk assessment methodologies. A combination of 'Good Practice', Engineering (or Environmental) Impact and Risk Assessment and Precautionary Approach are required.

ALARP is demonstrated when the precautionary approach is applied, such that it can be shown uncertainty is counterbalanced through conservative assumptions which include the 'worst-case' scenario that can be realised. Safety is expected to take precedence over economic considerations when completing a cost benefit analysis of additional controls.

6.3.4 Identification of Changes to Residual Impact and Risk

Following the ALARP evaluation, any changes to the predicted residual impacts and risks resulting from adopting alternate and/or additional control measures are identified to determine whether potential impacts and risks have been reduced to an acceptable level.

6.3.5 ALARP Statement

ALARP is demonstrated when it is apparent all available and effective control measures have been considered and implemented, where the cost is not grossly disproportionate to the environmental benefit gained from implementing the control measures. A corresponding statement of ALARP is provided for each event to justify the overall certainty and effectiveness of reducing potential impacts and risks to ALARP, using the adopted control measures.

6.4 Impact and Risk Acceptability

Regulation II of the Environment Regulations requires an EP to demonstrate that the environmental impacts and risks of the activity have been reduced to an **Acceptable Level**. Further, regulation 13(5)I states an EP must include details of control measures that will be implemented to achieve this. The criteria used to determine whether the residual risks and impacts of an activity following the implementation of the control measures, and following the demonstration of **ALARP**, are at an **Acceptable Level**, are contained within **Table 51**.

For each criterion, 'acceptability questions' have been developed to assess compliance. Each activity, both planned and unplanned, has been assessed against the relevant criteria within **Sections 7** and **8**.

Impacts and risks classified as Type A are characterised as 'Acceptable' if the level of residual impact and risk are determined to be Moderate or less and compliance with the acceptable impacts stated in **Table 51** can be demonstrated. Impacts and risks classified as Type B or above are characterised as 'Acceptable' if the requirements in **Table 51** can be demonstrated and it can be determined that the predicted levels of impact and residual risk are at or below pre-defined **Acceptable Level** for that impact or risk, including those described in **Table 52**.

Acceptable levels of impact and risk have been developed to protect the values of specific receptors which have been determined as relevant to the routine operations of the activity (**Table 52**). Where risks and impacts are identified as Type B or above, an assessment against these levels has been undertaken to determine whether the predicted impact and risk are below an acceptable level of impact.

Table 51 General Impact and Risk Acceptability Criteria

Criteria	Acceptability Questions	Acceptability is Confirmed
Residual risk ranking	Is the level of residual risk determined to be **Moderate** or less?	The risk has been determined to be **Moderate** or less.
Ecologically sustainable development	ESD is defined as '*using, conserving and enhancing the community's resources so that ecological processes, on which life depends, are maintained, and the total quality of life, now and in the future, can be increased*'. Section 3A of the EPBC Act sets out three main matters; the first of which is that the activity needs to be carried out in a manner consistent with the principles of ESD. Therefore, ESD is an integral aspect in determining risk/impact acceptability. Based on this, is the management of the risks/impacts associated with the proposed activities carried out in a manner that is consistent with the five principles of ESD as defined within the EPBC Act (**Section 2.1.2**)?	The Otway Basin 3D MC MSS is consistent with the five principles of ESD.

Criteria	Acceptability Questions	Acceptability is Confirmed
TGS' Internal context	Does the management of the risks/impacts associated with the activity align with the internal policy of the titleholder (in this case TGS' policies, **Appendix A**)?	Internal or external audits of procedural systems confirm all policies in place that align with the EP.
Existing environmental context	Has the development of the control measures taken into account the environmental values and sensitivities at a local, regional or global level, where relevant? Are the values and sensitivities of the environment, including matters protected under Part 3 of the EPBC Act (World Heritage, National Heritage, Wetlands of International Importance, Listed threatened species and ecologically communities, Listed migratory species, Commonwealth Marine Environment) protected so that no significant impacts result to the environment?	With the implementation of the control measures, the potential impacts from each of the activities must be consistent with the general nature and quality of the receiving environment of the OA and EMBA.
External Context – Management Plans, Species Recovery Plans and Conservation Advice	Is the management of the impacts/risks in accordance with the relevant species specific or protected area management plans, such as Conservation Advice, Management Plans, or Recovery Plans? Are the risks/impacts managed in alignment with the nominated conservation values defined within the South-east Marine Region Profile?	With the implementation of the control measures, the potential impacts from each of the activities must be consistent with all of the relevant management plans, conservation advice, recovery plans.
Social Acceptance – Relevant persons expectations	Have any concerns regarding the risks/impacts which may arise from the activity been raised through consultation (described throughout **Section 5** and **Appendix G**) with relevant persons. If so, have the merits of these concerns been evaluated? Where it has been determined that the concerns have merit, have any relevant control measures been developed to address these concerns?	All relevant persons concerns and submissions have been responded to, adequately addressed and closed out.
External Context – Commonwealth and State Legislative Criteria	Does the management of the risks/impacts (including the proposed control measures) associated with the activity align with the relevant Australian and International legislation, conventions, and standards such as those outlined within **Section 2** (i.e. Policy Statement 2.1, MARPOL, Marine Notices, Marine Orders)?	Compliance with all of the legislative requirements, standards and policies and can be demonstrated when audited.
Industry best practice	Has the management of the risks/impacts been conducted in accordance with industry best practice, such as the APPEA Code of Environmental Practice and IAGC Environmental Manual for Worldwide Geophysical Operation?	The impact of potential risk, through control measures is managed so that it is compliant with all relevant industry best practice guidelines.
ALARP	Are all reasonable and practicable control measures in place to reduce the impact or risk of the activity? Have the costs (financial or otherwise) of implementing further control measures been considered? Where it is considered that costs are disproportionate to the benefit gained, has this been identified?	General agreement that the residual risk from the Otway Basin 3D MC MSS has been demonstrated to be **ALARP**.

Table 52 Specific Impact and Risk Acceptability Criteria

Criteria	Acceptable Level	Acceptability is confirmed
Marine Environmental Quality	There are no long-term or widespread impacts to the quality of water and sediment.	Predicted impacts to water and sediment quality are short-term and localised.
Plankton	Impacts to plankton communities are localised (within 100s of m from the acoustic source) and recoverable (< 1 week to recover). Note that the latter is considered sufficient to protect against population level impacts and impacts to the recruitment levels at surrounding habitats.	Predicted impacts to plankton communities do not extend beyond the spatial and temporal limits defined within the acceptable level.
Benthic Habitats (Banks, Shoals and Reef)	No detectable impacts to habitat forming benthic primary producers, such as coral, as a result of the Otway Basin 3D MC MSS.	No impacts to habitat forming benthic primary producers are predicted
Benthic Invertebrates	Impacts to crustaceans and bivalves arising from the Otway Basin 3D MC MSS will not result in mortality rates beyond the natural range of variation.	Predicted impacts to crustaceans and bivalves do not indicate mortality rates beyond the natural range of variation.
Non-Listed Marine Fauna (Cephalopods, Fish, Sharks, Rays)	No serious[12] or irreversible damage to a population of any Non-listed marine fauna species as a result of the Otway Basin 3D MC MSS.	No serious or irreversible damage to a population of any Non-listed marine fauna species as a result of the Otway Basin 3D MC MSS.
EPBC Act Listed marine fauna (Marine Turtles, Marine Mammals, Seabirds)	Impacts to EPBC Act Listed marine fauna are limited to minor, short term effects to individuals and do not preclude the continuation of biologically important behaviours, within and outside nominated BIAs.	Predicted impacts to marine fauna are limited to minor, short term effects do not preclude the continuation of biologically important behaviours within and outside the nominated BIAs.
Marine Protected Areas and Sensitive Areas	Meet the Zeehan AMP and Nelson AMP IUCN Category VI (Multiple Use Zone) objective to provide for ecologically sustainable use while conserving ecosystems, habitats and native species. The Otway Basin 3D MC MSS is undertaken in a manner consistent with the requirements of the South-East Commonwealth Marine Reserves Network Management Plan 2013 - 23. The ecosystem function and integrity of Commonwealth Marine Areas are maintained.	Predicted impacts to Marine Protected Areas/Sensitive Areas do not compromise the ecosystem function and integrity of Marine Protected Areas/Sensitive Areas or conservation status of native species within Marine Protected Areas/Sensitive Areas. Predicted impacts do not compromise the ecosystem function and integrity of Commonwealth Marine Areas.

[12] In the absence of a definition of 'serious' environmental damage in relation to the Principles of ESD under the EPBC Act, TGS considers a serious impact to be impacts with the potential to result in a threat to population or community viability.

Criteria	Acceptable Level	Acceptability is confirmed
Cultural Heritage Values	No interference with other relevant persons/marine users, including access by traditional owners, to an extent greater than is necessary for the exercise of right conferred by the titles granted.	Predicted impacts to access and use (e.g. fishing) are managed such that they are not greater than is necessary for the exercise of right conferred by the titles granted.
Commercial Fisheries	No interference with other relevant persons/marine users to an extent greater than is necessary for the exercise of right conferred by the titles granted. No change to the sustainability status of the fishery; the Otway Basin 3D MC MSS is undertaken in a manner that does not result in serious, irreversible or long-term impacts to key indicator commercial fish populations and to the extent that sufficient spawning fish biomass and recruitment of the stocks may be maintained such that stocks continue to be assessed as sustainable. There is no increased costs or loss of income for commercial fishing license holders.	Predicted impacts to access and use are managed such that they are not greater than is necessary for the exercise of right conferred by the titles granted.
Commercial Shipping	No disturbance to shipping outside the extent of the (10 km) caution zone.	Impacts to shipping are not predicted to occur beyond the (10 km) caution zone.
Tourism and Recreation	No disturbance to tourism and recreation activities outside the extent of the (10 km) caution zone or to a degree exceeding that previously agreed to be an acceptable level of disruption to tourism operators and recreational users.	Impacts to Tourism and Recreation are not predicted to occur beyond the (10 km) caution zone or to a degree exceeding that previously agreed to be an acceptable level.
Divers	No health impacts to divers or underwater recreational activities as a result of the Otway Basin 3D MC MSS.	There are no predicted health impacts to divers or recreational users as a result of the Otway Basin 3D MC MSS.
Petroleum exploration and production	No entry into established Petroleum Safety Zones surrounding petroleum installations and equipment.	There is no unpermitted entry into established Petroleum Safety Zones surrounding petroleum installations and equipment.
	No disturbance to SIMOPS outside the extent of the (10 km) caution zone or to a degree exceeding that previously agreed to be an acceptable level of disruption to petroleum exploration and production vessel activities.	Impacts to SIMOPS are not predicted to occur beyond the (10 km) caution zone or to a degree exceeding that previously agreed to be an acceptable level.
	Where the potential for concurrent MSSs to occur is identified, SIMOPS planning will include the implementation of a 40 km spatial separation between the Seismic Vessel and any other operating Seismic Vessel in the Otway Basin area.	A 40 km spatial separation is maintained between the Seismic Vessel and any other operating Seismic Vessel in the Otway Basin area.

Criteria	Acceptable Level	Acceptability is confirmed
Defence activities	No disruption to known defence activities or damage to UXOs	No impacts to known defence activities are predicted.
Research Activities	No disturbance to Research Activities outside the extent of the (10 km) caution zone or to a degree exceeding that previously agreed to be an acceptable level of disruption to Researchers.	Impacts to Research Activities are not predicted to occur beyond the caution (10 km) zone or to a degree exceeding that previously agreed to be an acceptable level.

TGS considers an impact or risk to be unacceptable where the residual risk or impact attributed to a planned or unplanned event is High or greater, or, where the assessment shows the defined **Acceptable Level** cannot be met. In these cases, TGS will not undertake the activity until such a time where the residual impact and risk ranking are reduced to Moderate or below, or it can be demonstrated that the defined **Acceptable Levels** can be met.

6.4.1 Acceptability Statement

Following demonstration that all effective and practicable control measures have been adopted to reduce the impacts and risks to **ALARP**, compliance with the pre-defined (general and/or receptor specific) **Acceptable Levels** of impact has been assessed. A corresponding statement is provided for each event to justify the outcome of this assessment.

6.5 Environmental Performance Outcomes and Standards

Regulation 13(7)(a–c) of the Environment Regulations requires every EP to:

- Set out the environmental performance outcomes against which the performance of the titleholder in protecting the environment is to be measured;
- Set environmental performance standards for the control measures; and
- Include measurement criteria that the titleholder will use to determine whether each environmental performance outcome and environmental performance standard is met.

Environmental performance outcomes (**EPOs**) are a specified measurable level of environmental performance that titleholders are seeking to achieve for the life of the activity. The EPOs developed are designed to support the effective management of aspects of an activity to the extent that any associated environmental impacts and/or risks are of an **Acceptable Level**. To this end, the EPOs should be equivalent to or better than the acceptable levels(s). Each activity associated with the Otway Basin 3D MC MSS will include an environmental performance outcome which relates to all the environmental features that may be impacted or are at from the occurrence of the activity.

Environmental performance standards (**EPSs**) relate specifically to the performance of a control measure. They are parameters which control measures are assessed against to ensure they consistently perform to reduce the impact or risk to **ALARP** and to an **Acceptable Level**. These EPS' set levels at which an incident becomes a 'recordable incident' (**Section 10**) and will be utilised as part of performance monitoring of the Otway Basin 3D MC MSS.

Measurement criteria define how the environmental performance outcomes and standards will be measured to determine whether the outcomes have been met during the Otway Basin 3D MC MSS.

7 Environmental Impacts and Risks from Planned Activities

This section describes the results of the impact and risk assessment for planned activities using the methodology described throughout **Section 6** and identifies the control measures that will be in place to reduce the impacts and risks associated with the Otway Basin 3D MC MSS to **ALARP** and to an **Acceptable Level**.

The impact and risk assessment has been undertaken for each planned activity are listed in **Table 53**.

Table 53 Planned Activities Assessed

Planned activity	Section reference	Residual risk
Physical presence of Seismic Vessel and towed equipment	**Section 7.1**	**Low**
Acoustic disturbance to the marine environment	**Section 7.2**	**Moderate**
Routine permissible waste discharges	**Section 7.3**	**Negligible**
Atmospheric emissions	**Section 7.4**	**Negligible**
Artificial light emissions	**Section 7.5**	**Low**

7.1 Physical Presence of Seismic Vessel and Towed Equipment

7.1.1 Description of Source of the Impacts and Risks

The risk of a vessel collision or entanglement with marine fauna and other marine users is limited to the footprint of the vessel and towed equipment. During the Otway Basin 3D MC MSS, the Seismic Vessel will tow a suite of equipment including the acoustic source at a depth of 6—8 m below the surface, and up to 14 streamers. Each streamer will be 8 – 10 km in length and will be towed at 10 – 30 m below the surface. Streamers will have a lateral spread of 800 – 1,600 m. Each streamer will be equipped with a tail buoy that has a radar reflector and light at the terminal end. A detailed description of the proposed activity and schematic diagram showing the general configuration of towed gear is provided in **Section 3** and **Figure 3**.

A purpose-built Seismic Vessel will be contracted for the Otway Basin 3D MC MSS that is capable of safely operating in the environmental conditions of the Otway Basin. The Seismic Vessel will be accompanied by at least one support vessel, which will manage potential interactions between the Seismic Vessel and other marine users. The Seismic Vessel and support vessel/s are collectively referred to as the ‘survey vessels’, where appropriate, throughout this section.

7.1.2 Evaluation of Known and Potential Impacts and Risks to Environmental Receptors

Using the information presented in **Section 4** to **Section 5**, the impact and risk assessment has been undertaken for those receptors determined to be relevant to the activity as listed in **Table 54**.

Table 54 Environmental Receptors Assessed

Receptor	Section reference
Marine Reptiles	**Section 7.1.2.1**
Marine mammals (cetaceans and pinnipeds)	**Section 7.1.2.2**
Seabirds	**Section 7.1.2.3**
Protected areas	**Section 7.1.2.4**

The physical presence of the survey vessels and towed acoustic equipment has the potential to result in the following effects on environmental receptors, including those that are recognised as key sensitivities within the protected areas that overlap with the OA:

- Disruption to normal animal behaviours;
- Displacement of animals from preferred habitat; and
- Collision with or entanglement of animals in towed equipment.

7.1.2.1 Marine Reptiles

Three species of threatened marine turtle are known to occur, or may occur, within the OA (**Table 24**): loggerhead turtle, green turtle, and leatherback turtle. The greatest potential consequence to these marine reptiles from the physical presence of the survey vessels and towed equipment, is collision or entanglement.

Turtles are vulnerable to vessel strike due to their relatively small size and the significant amount of time spent just below the sea surface (Commonwealth of Australia, 2017a). Peel *et al*. (2016) reviewed vessel strike data (2000 – 2015) for marine turtles in Australian waters and identified that all marine turtle species present in Australian waters have had interactions with vessels, with green and loggerhead turtles (both of which may occur within the OA) exhibiting the highest incidence of interactions.

Tail buoys are the most likely part of the towed equipment to trap marine turtles. There are two main areas on the tail buoy which may trap turtles: between the buoy and the connecting chains (the most common area of entrapment), or underneath the buoy in the ‘undercarriage’ structure (Ketos Ecology, 2009). To become trapped in the tail buoy, the animal would have to come in close proximity to the buoy. There are two theories as to why turtles become trapped against tail buoys: startle diving in front of the towed equipment, or while foraging along the streamers (Ketos Ecology, 2009). Entanglement in tail buoys would be fatal due to water movement holding the turtle against the buoy, keeping the turtle from being able to reach the surface to breathe (Ketos Ecology, 2009).

Collision avoidance is determined by the animal’s response time, which is affected by both vessel speed and visibility. Hazel *et al*. (2007) found that 60% of green turtles were able to successfully flee from approaching vessels travelling at two knots (3.76 km/hr). A turtle’s ability to flee was severely reduced as vessel speed increased, with 22% of turtles successfully fleeing at six knots (11.1 km/hr) and only 4% at ten knots (18.5 km/hr). The authors concluded that most turtles cannot avoid vessels travelling at speeds greater than two knots (Hazel *et al.,* 2007). Turtles are likely responding to visual cues of the approaching vessel, not sound cues; if turtles were relying on sound, the reverse result would occur with greater response rates to faster (i.e. louder) vessel approaches (Hazel *et al*., 2007).

Surface behaviours of marine turtles increase the chance of entrapment. Those basking at or just below the sea surface in hot and calm conditions react slowly to oncoming threats, with dive reactions occurring at close range based on visual detection of the threat (Ketos Ecology, 2009). Startle responses in animals undertaking such behaviours in response to approaching vessels have been observed at as little as 1 m from the threat (Weir, 2007). All species of marine turtle potentially present within the OA exhibits basking behaviours.

There are no peer-reviewed literature documenting incidences of marine turtle entanglement; however, there are anecdotal reports of marine turtles off the west coast of Africa, leading to the development of ‘turtle guards’ (Nelms *et al.,* 2016). Turtle guards are fitted to the buoy and act as a physical barrier to exclude turtles from the space between the buoy and undercarriage (Ketos Ecology, 2009). Certain designs may also allow the turtle to be deflected away from the buoy. All tail buoys utilised in the Otway Basin 3D MC MSS will be fitted with a turtle guard unless the tail buoys are of a design that does not represent an entrapment risk to marine turtles.

The '*National Strategy for Reducing Vessel Strike on Cetaceans and other Marine Megafauna'* provides a guiding framework for mitigating the risk of vessel collisions with marine megafauna, including marine turtles (Commonwealth of Australia, 2017a). An intended outcome of this document is the development of a mitigation measures 'toolkit'. To date this toolkit has not yet been developed.

There are no mitigation measures that will be implemented on board the Support Vessel to minimise the risk of collision with marine turtles; however, the installation of turtle guards on tail buoys or use of buoys of a design that does not represent an entrapment risk to marine turtles, and the slow speed of the Seismic Vessel are considered to be effective measures against ship strike and entanglement for marine turtles. Any incidents with turtles will be reported, as recommended under the National Strategy.

Disruption to normal animal behaviours and displacement from preferred habitat due to vessel disturbance is particularly an issue for turtles in foraging habitats and nesting areas, particularly in shallow coastal areas where vessel traffic is typically high (Commonwealth of Australia, 2017a). Much of the OA is in water depths greater than 400 m which is typically outside of the preferred depth range for marine turtles. Furthermore, there are no marine turtle BIAs within either the OA or the wider EMBA, therefore the OA has not been identified as being particularly important habitat for marine reptiles and disruption of marine turtles from preferred habitat will not occur during the Otway Basin 3D MS MSS.

The residual risk to marine turtles arising from the physical presence of the survey vessels and towed equipment during the Otway Basin 3D MC MSS has been assessed as **Low** (*Minor* x *Unlikely*).

7.1.2.2 Marine Mammals

Disruption of normal animal behaviour and displacement is of particular concern when it occurs frequently or over a prolonged period and affects critical behaviours such as feeding, breeding, and resting. The physical presence of the survey vessels and towed equipment may cause some temporary and localised changes in marine mammal behaviours and/or displacement from habitat. **Table 37** provides a summary timeline depicting the expected presence of marine mammals in the OA.

The reaction of marine mammals to the approach of a vessel is variable, however, marine mammals generally show two stereotypical behaviours in the presence of vessels: avoidance or attraction (Wűrsig *et al*., 1998); both behaviours can affect energy expenditure and disrupt natural activities. Avoidance most commonly leads to an animal becoming displaced from an area; however, such disturbance is predicted to be temporary due to the transitory and temporary duration of seismic activities in any single location. Furthermore, marine mammals must be in relative proximity to the vessels and equipment to be affected by their physical presence. Whales generally do not approach moving ships, while dolphins may bow ride vessels depending on the species, their behaviour, and the vessel type.

Collisions between vessels and marine mammals occur more frequently where high vessel traffic and important habitat coincide. Vessel strike incidents involving whales have been reported from all areas of the Australian coastline except for the northern coast, where population density, vessel traffic, and the number of whales present are relatively lower (Peel *et al*., 2018). The timing of reported vessel strike incidents tends to match the migratory patterns of the species involved, for example, incidents involving SRWs in Australia peak in August, corresponding to when this species is migrating and/or have reached mating/calving grounds close to the Australian coastline (Peel *et al.,* 2018).

The Commonwealth of Australia (2017b) reports that there were 109 records of ship strike on cetaceans in Australian waters from 1997 to 2015. Species affected included humpback (47%), SRW (13%), sperm (3%), PBW (2%), BW (2%), pygmy sperm (2%), dwarf minke (2%), pygmy right (1%), fin (1%), Antarctic minke (1%), and 'unidentified' (26%) whales (Commonwealth of Australia, 2017b). Peel *et al*. (2018) revised this data and added to it by searching media archive databases and revealed an additional 76 unreported vessel strike records between 1877 and 2015. Overall, Peel *et al.* (2018) concluded that of the 'known' species in the Australian ship strike record, humpback whales (59%), SRWs (14%), and sperm whales (8%) were the most encountered species. Incidents typically occurred within each species' core distribution (for SRWs and sperm whales this was confined to the southern half of Australia) and there was a strong temporal correlation between ship strike and migration periods for humpback and SRWs. Globally, the species most affected by vessel strike are fin whales, humpback whales, right whales, gray whales, minke whales, sperm whales and BWs (Jensen *et al*., 2004).

Laist *et al.* (2001) suggested larger vessels (i.e. container vessels and fast ferries) moving faster than 10 knots may cause fatal or severe injuries to cetaceans, with the most severe injuries caused by vessels travelling at speeds greater than 14 knots. Vanderlaan and Taggart (2007) found the greatest increase in probability of lethal injury to a large whale involved in a ship strike incident was between vessel speeds of 8.6 and 15 knots. Individual cetaceans engaged in behaviours such as feeding, mating, or nursing may also be more vulnerable to vessel collisions when distracted by these activities (CoA, 2017b). Peel *et al*. (2018) collated all known reports of vessel strike on whales in Australian waters and found over half of reports (53%) for where the outcome of the interaction was known were fatal or likely fatal for the animal involved. Fatalities often occurred due to interactions with the propeller of larger vessels (Peel *et al*., 2018). During data acquisition, seismic vessels typically travel at approximately 4 – 5 knots; three to four times slower than the mean fatal speed documented by Jensen *et al*. (2004). Records of sub-lethal effects are less reliable on account of the difficulty in assessing injury in free swimming cetaceans following a collision.

Jensen *et al*. (2004) demonstrated that vessel type plays a role in the likelihood of a ship strike resulting in animal mortality. In a review of the global ship strike database, most fatal strikes were caused by navy vessels and container/cargo ships/freighters, which typically travel faster than 15 knots. Seismic vessels (categorised in the study as 'research' vessels) accounted for only one ship strike incident from a total of 292 reported incidents (Jensen *et al*., 2004).

There are 26 cetacean species identified within the EPBC Act Protected Matters Search as having a potential presence within the OA (see **Table 25**). The OA overlaps with PBW distribution and foraging BIAs (**Figure 23**), and the known core range and aggregation areas (identified as BIAs) for SRWs (**Figure 24**). Based on the assessed likelihood of encountering each cetacean species during the Otway Basin 3D MC MSS, ship strike is of most concern for BW, fin, sei, SRW, humpback, and pygmy right whales which are known or likely to occur in the OA.

While PBWs are not well represented in the Australian ship strike records, collisions do occasionally occur. Strandings of BWs with suspected vessel strike injuries were recorded in VIC near the Bonney Upwelling in 2009 – 2010, with increased recreational fishing at continental shelf waters off Portland increasing the potential for collisions to occur (DoE, 2015b). BWs have been shown to have limited ability to adjust their response behaviour to approaching ships, with McKenna *et al.* (2015) reporting BWs with relatively slow descents and no horizontal movements away from a ship in their study. Owen *et al.* (2016) also found BWs dived to a mean depth of ~13 m while on migration, spending 94% of observed time within the range of large container ship drafts (<24 m), although it is unclear how diving behaviour differs for foraging whales.

SRWs are vulnerable to entanglement and vessel collision as they spend significant portions of the year in coastal waters where human activities are most concentrated. This is of relevance to the Otway Basin 3D MC MSS with the identification of coastal waters between Sydney and Perth as a core range BIA. During experimental approaches of a research vessel towards SRWs off the coast of Argentina, Argüelles *et al.* (2021) found differing responses of SRWs depending on the number of whales present. The authors concluded that the probability of a SRW responding to a transiting vessel is low, unless there are only a few whales in a group, or it is a mating group, as the approaching vessel was not perceived as a threat (Argüelles *et al.,* 2021). Due to the distance offshore of the OA, the SRWs encountered during the Otway Basin 3D MC MSS will likely be adult whales and densities will be very low. Based on the findings of Argüelles *et al.* (2021), these whales may show slow or reduced responses to the approaching Seismic Vessel.

TGS will implement additional controls to mitigate against effects of the Otway Basin 3D MC MSS on BW/PBWs and SRWs. These controls include both spatial and temporal restrictions for acquisition in and around the BW/PBW foraging BIAs and SRW Aggregation BIA (as depicted in **Figure 23** and **Figure 24** respectively), which have been identified as key sensitivities for these species. Of particular note are the following spatio-temporal controls that reduce the overlap between seismic operations and elevated seasonal densities of these key threatened species:

- No acquisition will occur within the BW/PBW BIAs or a 16 km buffer during the 'peak feeding season' from January to June (inclusive) based on the expected consistent and widespread presence of whales in the foraging areas during these months (Gill *et al*., 2011; 2015; McCauley *et al*., 2018). The only exception allowed is the acquisition of the 2D tie line which will be subject to additional operational restrictions and will only take approximately 12 hours to acquire.
- No acquisition will occur within the SRW Ag BIA or a 42 km buffer during the core aggregation months of May to September (SWIFFT, 2023) and no exceptions will be permitted.

These control measures have been further described within **Section 7.2** and the associated control measure and EPS tables pertaining to potential effects of acoustic emissions on marine mammals.

The slow operational speed of the Seismic Vessel and the presence of MFOs onboard will also serve as strong control measures against any potential ship strikes.

Smaller dolphin species are highly agile and are significantly less likely to collide with larger vessels (Van Waerebeek *et al*., 2007) and as a result vessel strike for these species during the Otway Basin 3D MC MSS isa remote concern.

Minimising vessel collision is ranked as a high priority action within the Conservation Management Plans for BWs and SRWs, and within the Conservation Advice for fin, sei, and humpback whales. The expected low incidence of vessel strike from the Otway Basin 3D MC MSS will not affect the long-term recovery of these species in accordance with these plans.

The '*National Strategy for Reducing Vessel Strike on Cetaceans and other Marine Megafauna*' acts as a guiding framework for identifying the species and areas most at risk and aims to provide appropriate control measures to reduce the risk of ship strike. The National Strategy intends to develop a 'mitigation measures toolkit'. To date this toolkit has not been developed; however, once developed the control measures for cetaceans will fall into three main categories: keeping vessels away from whales, slowing of vessel speeds, and implementation of avoidance manoeuvres (Commonwealth of Australia, 2017b).

The master of the Support Vessel will operate in accordance with the EPBC Regulations Part 8, Division 8.1 in regard to the minimum approach distances and vessel speed for "other craft" and follow the prescribed actions when adult cetaceans and/or calves are present within the caution zone[13]. These control measures are included in **Table 84**. In particular, EPBC Regulations Part 8, Division 8.1 requires the Vessel Masters of the Support Vessel/s to:

- Take action to avoid approaching or drifting closer than 50 m to an adult dolphin or 100 m to an adult whale;
- Take action to avoid approaching or drifting closer than 150 m to a dolphin calf or 300 m to a whale calf; and
- Not exceed a speed of 6 knots within the caution zone of a cetacean (300 m).

If the cetacean shows any sign of being disturbed, the vessel must be withdrawn from the caution zone at a speed of less than 6 knots. If an adult whale approaches the Support Vessel or comes within 100 m, the master must disengage the gears and let the whale approach or reduce the speed of the vessel and continue on a course away from the whale. If an adult dolphin approaches the Support Vessel or comes within 50 m, the master must not suddenly change course or speed of the vessel. The master of the Support Vessel will make all efforts not to let a calf enter the caution zone; however, if a calf does enter the caution zone, then the master will immediately stop the vessel, turn off the vessel's engines, or disengage the gears, or withdraw the vessel from the caution zone at a constant speed of less than 6 knots.

Due to the restricted manoeuvrability of the Seismic Vessel, no further mitigation measures can be applied to reduce the risk of ship strike from the Seismic Vessel; however, the Seismic Vessel will maintain speed and course in the presence of marine mammals, this, in addition to the already low speed of the vessel, allows greater time for individuals to detect the vessel, predict its pathway, and avoid a collision or entanglement in the towed equipment. Trained observers will be on-watch while the Seismic Vessel is acquiring during daylight hours. While this will not minimise the potential for vessel strike, any incidents (i.e. ship strike or entanglement) will be observed and reported. Ship strikes will be reported into the Australian Government National Ship Strike Database, as is required by the EPBC Act.

A foraging BIA for male Australian sea lions is located 97 km from the northwest boundary of the OA. This species generally feeds on the continental shelf, most commonly in depths of 20 – 100 m, and travel a maximum distance of around 190 km when over shelf waters (Shaughnessy, 1999). Although Australian sea lions have been identified within the Protected Matters Report as present within the OA, given the distance of the OA from the foraging BIA and from the main breeding colonies at Pages Islands (over 360 km) and Seal Bay (over 400 km), it is unlikely that Australian sea lions will be encountered in the OA.

Although some marine mammals could interact with and become entangled in the towed equipment, it is highly unlikely that this would occur on account of marine mammals displaying exceptional abilities to detect and avoid obstacles in the water column and there being no loose surface lines associated with the towed equipment (Rowe, 2007). To TGS' knowledge, there has never been a reported case of a marine mammal becoming entangled in seismic equipment. In addition, the auditory range of many cetaceans overlaps with peak intensities of transiting ships, thus cetaceans should have the capacity to acoustically detect an oncoming ship (Allen and Peterson, 2012) and move away from the vessel/s, minimising the likelihood of a ship strike and entanglement.

[13] 150 m radius around a dolphin, and 300 m radius around a whale

The presence of the vessels may also act as an attractant to certain species, particularly smaller species of dolphin which may approach the vessel to bow-ride (Wűrsig *et al*., 1998). Bow-riding behaviours have been observed during periods of active seismic acquisition (e.g. Moulton and Miller, 2005). However, the seismic array is located a reasonable distance behind the bow waves that small dolphins like to play in.

As a result, the risk to marine mammals arising from the physical presence of the survey vessels and the towed equipment during the Otway Basin 3D MC MSS has been assessed as **Low** (*Minor* x *Unlikely*).

7.1.2.3 Seabirds

Seabird interactions with vessels are relatively common in marine waters. While most interactions are harmless, some can be detrimental and may cause injury or death (e.g. bird strike). Seabird shave been shown to respond to vessels by avoidance of heavily used areas and disruption of feeding behaviours (Schwemmer *et al*., 2011; Velando and Munilla, 2011; Ronconi *et al*., 2015).

Several seabird species identified as potentially present within the OA are known to follow vessels due to a learned association of vessels as a food source (e.g. fishing vessels discarding fish offal). These include several species of albatrosses, petrels, and shearwaters. These species tend to follow the vessel and are therefore unlikely to collide with the moving vessel.

The risk of vessel collision or entanglement with towed equipment is limited to the footprint of the survey vessels, which is temporary in nature at any one position as the vessels transit the OA. The Seismic Vessel will be operating at low speeds while acquiring data for the Otway Basin 3D MC MSS, and as such, it is expected that most seabirds in the vessel's path will relocate to avoid collision as is typical of most interactions between vessels and seabirds. The OA overlaps with foraging BIAs of 12; however, the area of displacement will be small compared to the wider surrounding habitat and foraging birds will be able to continue exhibiting foraging behaviours immediately following the passage of the survey vessels.

Potential impacts of the acoustic source on seabirds and their prey (i.e. fish and zooplankton) are assessed throughout **Section 7.2**. Potential impacts from artificial light, including attraction of seabirds to the vessels and associated risk of vessel strike are assessed in **Section 7.5.2.4**.

The residual risk to seabirds arising from the physical presence of the survey vessels and towed equipment during the Otway Basin 3D MC MSS has been assessed as **Low** (*Minor* x *Unlikely*).

7.1.2.4 Protected Areas

The OA overlaps the boundaries of two AMPs (the Zeehan and Nelson AMPs) and one KEF (the West Tasmania Canyon KEF).

Key sensitivities within the West Tasmania Canyon KEF are primarily associated with the benthic environment and therefore will not be impacted by the physical presence of the survey vessels and towed equipment. Potential impacts on the benthic environment relating to an accidental streamer loss are assessed in **Section 8.2**.

Key sensitivities within the Zeehan AMP include benthic habitats, migrating blue and humpback whales, and foraging seabirds (black browed, wandering, and shy albatrosses, great winged petrels, and cape petrels), while sensitivities within the Nelson AMP include benthic habitats and migrating blue, humpback, fin, and sei whales. Benthic sensitivities within the AMPs will not be affected by the physical presence of the survey vessels and towed equipment. Potential impacts on marine mammals and seabirds from the physical presence of the survey vessels and towed equipment are addressed in **Section 7.1.2.2** and **Section 7.1.2.3** respectively.

The South-East Commonwealth Marine Reserves Network Management Plan 2013 – 23 has identified noise pollution associated with shipping/other vessels, and oil pollution associated with other vessels as sources of pressure on the conservation values of the AMPs within the SEMR; however, vessel transit is an allowed activity under Part 5 of the plan as it is an activity that is known to be likely to have minimal, if any impact on the values of the network management zones. Potential impacts from noise pollution and oil pollution as a result of the Otway Basin 3D MS MSS are addressed in **Section 7.2** and **Section 8.3** respectively.

7.1.3 Evaluation of Known and Potential Impacts and Risks to Relevant Persons and Marine Users

Using the information presented in **Section 4** to **Section 5**, the impact and risk assessment has been undertaken for those receptors determined to be relevant to the activity as listed in **Table 55**.

Table 55 Relevant Persons and Marine Users Assessed

Receptor	Section reference
Commercial Fisheries	**Section 7.1.3.1**
Commercial Shipping	**Section 7.1.3.2**
Tourism and Recreation	**Section 7.1.3.3**
Petroleum Exploration and Production	**Section 7.1.3.4**

The physical presence of the survey vessels and towed acoustic equipment has the potential to result in the following effects on relevant persons and other marine users:

- Displacement of marine users from regular routes or activity areas; and
- Collision with or entanglement of marine users with survey vessels and/or towed equipment.

The effects of displacement on relevant persons and other marine users due to an oil spill have been assessed in **Section 8.3** and **Section 8.4** (clean up response).

7.1.3.1 Potential Impacts and Risks to Commercial Fishing Operations

The following represent the potential impact pathways commercial fishers could be affected by the presence of the survey vessels and towed equipment:

- Temporarily exclusion of fishers from fishing grounds and inconvenience to fishers as they will need to plan their fishing operations around the planned survey routes, with potential additional costs incurred (e.g. additional fuel use, crew wages etc.); and
- Requirement to remove or delay the setting of fishing equipment within the OA during the acquisition period.

While towed equipment is deployed, the Seismic Vessel will be restricted in its ability to manoeuvre while moving at a speed of 4 to 5 knots. The limited manoeuvrability of the Seismic Vessel prevents active avoidance of fishers and fishing gear in the water and means that commercial fishing vessels may be asked to take measures to avoid the immediate vicinity of the Seismic Vessel and associated towed equipment. For commercial fishers this could result in operational inconveniences (e.g. manoeuvring around the Seismic Vessel and requested area of avoidance) and temporary loss of access to fishing areas (i.e. displacement). Displacement could result in reduced catches and income and/or increased costs to operate elsewhere (i.e. relocation costs). Vessels will be requested to provide a wide berth of 3 NM (5.5 km) ahead, on both sides, and astern of the Seismic Vessel and towed equipment. In addition, commercial fishers may be asked to remove deployed fishing gear such as pots and lines to avoid interaction with the Seismic Vessel and towed equipment. Fishers will continue to be able to fish within the OA; however, they will be temporarily impacted by the physical presence and buffer zone imposed around the Seismic Vessel and towed equipment.

The Seismic Vessel will be accompanied by at least one support vessel when safe to do so. The survey vessels will proactively and collaboratively manage operational information between the survey vessels and commercial fishers in the OA. The Otway Basin 3D MC MSS will adhere to the requirements of the COLREGS and Chapter 5 of the of Safety of Life at Sea (**SOLAS**), as implemented in Commonwealth waters through the Navigation Act 2012 and associated Marine Orders.

In the event that impacts to commercial fishing operations cannot be avoided, all evidence-based compensation claims made by commercial fishing licence holders for reduced catch or other costs incurred due to displacement by the Otway Basin 3D MC MSS, or for equipment damage/loss will be assessed for merit in accordance with the TGS Commercial Fisheries Compensation Protocol (see **Section 7.2.3.1 and Appendix N**) which has been developed in accordance with the National Energy Resources Australia Collaborative Seismic Environment Plan Project – Commercial Fishing Industry Adjustment Protocol.

The OA and AA for the Otway Basin 3D MC MSS were defined taking into consideration commercial fishing activities within the Otway Basin. With the exception of the 2D tie line AA (water depth 115 m, **Figure 4**), the AA is located in water depths greater than 510 m and avoids areas of high fishing effort by many commercial fisheries (see **Figure 48** to **Figure 66**). There are several Commonwealth and State managed commercial fisheries that have historically had catch effort with the OA (see **Section 4.7.3**). A brief assessment has been undertaken within **Sections 7.1.3.1.1** to **7.1.3.1.4** for those fisheries that have reported overlap with the OA.

7.1.3.1.1 Commonwealth Fisheries

7.1.3.1.1.1 Commonwealth Trawl Sector

The CTS has been identified as one of the main fisheries with a potential for interaction with the Otway Basin 3D MC MSS.

The CTS operates year-round and will therefore have a temporal overlap with the Otway Basin 3D MC MSS. However, ABARES fishing effort data for 2016 – 2020 indicates that fishing effort is primarily concentrated along the edge of the outer continental shelf and upper slope, typically in waters shallower than 700 m or 1,000 m depending on closure areas in the western zone of the fishery. Areas of low to high relative intensity overlap with the northern and eastern boundaries of the OA and AA in waters offshore of the South Australia/VIC border and off western TAS (**Figure 48**). The CTS will therefore only be disrupted if a survey phase involves seismic acquisition and vessel movements in water depths less than 1,000 m.

Trawlers within the CTS used a mobile method of fishing, and although their method of fishing has no fishing gear deployed and left on the seabed for any period of time, they may experience some displacement from the OA. However, this will be temporary in nature, with fishing being able to re-commence following the passage of the Seismic Vessel and towed equipment. Fishing effort will also be able to continue within the OA in areas outside of the influence of the Seismic Vessel and towed equipment.

7.1.3.1.1.2 Scalefish Hook Sector

The SHS targets similar stocks as the CTS. ABARES fishing effort data for 2016 – 2020 indicated that fishing effort is generally reported as <5 vessels per 60 NM reporting block, with only a few areas of fishing intensity mapped off southern and eastern TAS (**Figure 49**). As a result, there is potential for interactions between the SHS and the Otway Basin 3D MC MSS, however, this interaction will be limited to relatively low numbers of vessels.

7.1.3.1.1.3 Gillnet, Hook and Trap Sector – Shark Gillnet Sub-Sector

Fishing effort in the GHTS Shark Gillnet Sub-Sector occurs in continental shelf waters off VIC, TAS, and South Australia. Most vessels appear to fish in the central Bass Strait and in waters off Southern Australia, as evidenced by mapped areas of low – high fishing intensity for 2016 – 2020 (**Figure 50**). The areas of low – high fishing intensity lies outside the boundaries of the OA, with fishing effort within the OA limited to relatively few vessels (<5 vessels per 60 NM block).

7.1.3.1.1.4 Gillnet, Hook and Trap Sector - – Shark Hook Sub-Sector

Fishing effort within the GHTS Shark Hook Sub-Sector occurs in continental shelf waters off VIC, TAS, and South Australia, with most vessels fishing in waters off South Australia and north-east TAS, where areas of low – high fishing intensity have been mapped by ABARES for 2016 – 2020. These areas of low – high fishing intensity are largely outside of the OA, with fishing effort within the OA limited to relatively few vessels (<5 vessels per 60 NM block per year) (**Figure 51**). There is potential for interactions between the GHTS Shark Hook Sub-Sector and the Otway Basin 3D MC MSS; however, this interaction will be limited to relatively low numbers of vessels.

7.1.3.1.1.5 Southern Squid Jig Fishery

Fishing effort within the SSJF is highly variable due to the fluctuating market value of the target species, Gould's squid. The OA primarily overlaps with 60 NM blocks reported as having <5 vessels per year, although an area of low – high intensity was identified on the outer continental shelf off Portland, VIC, along the northern boundary of the OA (**Figure 53**).

The potential for interaction with this fishery is dependent on whether it is actively targeting squid at the time of the Otway Basin 3D MC MSS. The SSJF will only be disrupted if a survey phase involves seismic acquisition and vessel movements in water depths less than 1,000 m during an active period of the fishery.

7.1.3.1.1.6 Southern Bluefin Tuna Fishery

The potential for interaction with the SBT purse seine fishery depends on the location of fishing activities in any given season, however, in the period between 2016 and 2020, there has been no overlap in fishing effort within the purse seine fishery and the OA (**Figure 55**), with effort becoming increasingly focused in the eastern part of the fishery in waters off South Australia.

Although fishing effort within the SBT long-line fishery is mainly concentrated off the coast of NSW, low levels of fishing intensity has occurred off the coast of VIC in waters that overlap with the OA. This fishing effort has been limited to <5 vessels per 60 NM block for the period 2016 – 2020 (**Figure 56**).

Interaction with this fishery is potentially complex given that juvenile SBT caught in purse seine nets are then transferred to tow cages and towed at low speeds to Port Lincoln, South Australia. As a result, interactions with the SBTF could include both fishing and tow vessels.

During engagement with relevant persons (**Section 5**), Tuna Australia advised that as quota for SBT increases, the long-lining fishery sub-fishery of the SBTF (associated with long liners in the ETBF) may expand in the coming years form the east coast to include a greater level of fishing and searching for new fishing grounds off TAS and VIC. The quota fished for the long ling sub-fishery occurs after the quota by the purse-seine fishery has been caught or the season ended, therefore long-liners tend to fish between April and December. Long liners may also access deeper offshore waters than the purse seine sub-fishery. Given limited previous effort by long liners in the OA, the potential extent and magnitude of interactions is difficult to predict until such shifts in the fishery occur. Generally, it is considered that a survey phase could limit the ability of long liners to access new fishing grounds in the area.

TGS has been engaging with ASBTIA (and other representatives for the SBTF) throughout the preparation of this EP. As part of the engagement process with ASBTIA, TGS developed a Southern Bluefin Tuna Assessment Area across the OA towards South Australian waters. The intention of this Assessment Area is to manage the potential risk to both SBT behaviour during SBTF fishing and towing operations, and to divers involved in the fishing operations. When operating within Assessment Area, TGS proposed to:

- Notify ASBTIA of the proposed survey activities at least 4 weeks prior to commencement;
- Conduct a joint risk assessment with ASBTIA and share vessel contact details prior to commencing acquisition;
- During acquisition, maintain direct communication between the seismic vessel and SBT fishing and tow vessels;
- Based on reported experience of SBT fishing and tow vessels as the seismic vessel approaches areas of SBT fishing or towing activities, stand-off and adaptive management measures, as agreed to in the joint risk assessment, will be implemented; and
- MFOs on board the survey vessels will record the locations of any SBT at the surface and will communicate these to SBT fishing and tow vessels and to ASBTIA.

The approach was intended to find an amicable approach to managing simultaneous operations that allows both industries to conduct their operations while the seismic vessel approaches. Management would be adaptive on-the-water observations at the time. However, following subsequent feedback from both the tuna industry and other relevant persons, the OA was reduced and no longer covers the South Australian waters that were covered under the Southern Bluefin Tuna Assessment Area. Several of the proposed measures to be adopted within the Assessment Area are routine control measures that will be adopted throughout the OA and therefore will remain for the Otway Basin 3D MC MSS. For example, all survey vessels will be in radio contact at all times with other marine users, and all relevant persons will be given notification of the Otway Basin 3D MC MSS four-weeks prior to the commencement of the survey. Furthermore, TGS will provide any sightings of tuna aggregations to ASBTIA made from the survey vessels or during periodic aerial surveys.

Given the potential complexity of interactions with the SBTF and high value of the catch, it is recognised that some uncertainty remains regarding potential interactions with expanding long line operations. However, given that a survey phase will occupy discrete area and SBT are highly mobile throughout the region, alternative areas will be accessible outside of the survey phase.

7.1.3.1.1.7 Eastern Tuna and Billfish Fishery

The northern part of the OA overlaps with blocks were <5 vessels per year are reported to have fished during the period 2016 – 2020 (**Figure 54**). To date, fishing has not occurred here every year during this period. Based on infrequent, and low historical fishing effort, the potential for interaction is limited, however, fishing effort could increase in this region in association with the SBTF, as assessed in **Section 7.1.3.1.1.6.**

7.1.3.1.2 Victoria Fisheries

7.1.3.1.2.1 Rock Lobster Fishery

Fishing effort within the VIC Rock Lobster Fishery primarily occurs on the continental shelf and is greatest in water depths less than 100 m. A relatively low level of fishing effort has occurred along the northern boundary of the OA in the period 2016 – 2020, with all blocks overlapping the AA experiencing 1 – 30 fishing days across this period (**Figure 58**). Water depths within the AA range between approximately 100 m and 1,000 m. It is understood from consultation with rock lobster industry representatives that fishing in the deep waters happened occasionally when targeting 'white fish' to bulk up an order for a large amount of lobster meat.

Overall, the OA and AA avoids the most target areas within the Rock Lobster Fishery, with only a low effort of fishing activity in deeper waters of the OA and AA when targeting white fish. Acquisition of the 2D tie line will extend into shelf waters (minimum depth 114 m), although this tie line represents less than a day of survey effort and any disruption will be minimal.

7.1.3.1.2.2 Giant Crab Fishery

Fishing effort within the VIC Giant Crab fishery overlaps along the northeast of the OA and AA, with greatest fishing effort occurring in five blocks overlapping water depths less than 1,000 m (**Figure 59**). The precise location of fishing effort within the blocks cannot be confirmed, but according to VFA, giant crabs mainly occur at approximately 200 m depth. The majority of the OA and AA occur in deeper waters.

Interaction with fishing vessels and pots will only occur if a survey phase involves sail lines up to the edge of the AA at a time when fishing effort is targeting deeper waters that the core range of giant crab. TGS will adopt a Giant Crab Exclusion Zone (see **Section 7.1.3.1.3.2**) over water depths shallower than 1,000 m to the south of the 2D tie line extension. While this is primarily to protect giant crab fishing effort in the TAS Giant Crab Fishery, it also reduces overlap with giant crab habitat and fishing grounds in the VIC Giant Crab Fishery.

7.1.3.1.2.3 Ocean Fish General Fishery

A single fishing block for the VIC Ocean Fish General Fishery overlaps the northern boundary of the OA and AA (**Figure 60**). This represents a single day reported by one fisher in 2020, therefore interaction with fishing vessels in this fishery is highly unlikely.

7.1.3.1.3 Tasmanian Fisheries

7.1.3.1.3.1 Rock Lobster Fishery

Fishing within the TAS Rock Lobster Fishery is greatest in the waters surrounding King Island, with the OA overlapping slightly with an area fished by 51 – 75 vessels per year (**Figure 61**). In all other blocks overlapping the OA and AA, fishing effort is <5 vessels per year. Fishing effort is expected to be concentrated inshore of the OA, with some limited effort in deeper waters along the OA boundary.

TGS will implement a Giant Crab Acoustic Exclusion Zone to protect the TAS Giant Crab Fishery. This will also serve to protect the TAS Rock Lobster Fishery.

7.1.3.1.3.2 Giant Crab Fishery

Fishing effort within the TAS Giant Crab Fishery primarily takes place in water depths less than 400 m, however, the OA and AA overlap with an area of high fishing effort to the south-east of King Island (**Figure 62**).

TAS Giant Crab representatives engaged with during the preparation of this EP state that fishing for giant crab sometimes occurs at depths greater than 400 m. Following feedback during the relevant persons engagement process, in order to protect giant crab within deeper habitats within the OA and AA, TGS will implement a Giant Crab Acoustic Exclusion Area (**Figure 74**), within which there will be no activation of the acoustic source. This area covers the waters along the eastern boundary of the OA and AA that are 1,000 m or less. With the implementation of the Giant Crab Acoustic Exclusion Area, interaction with vessels and pots associated with the TAS Giant Crab Fishery is expected to be avoided.

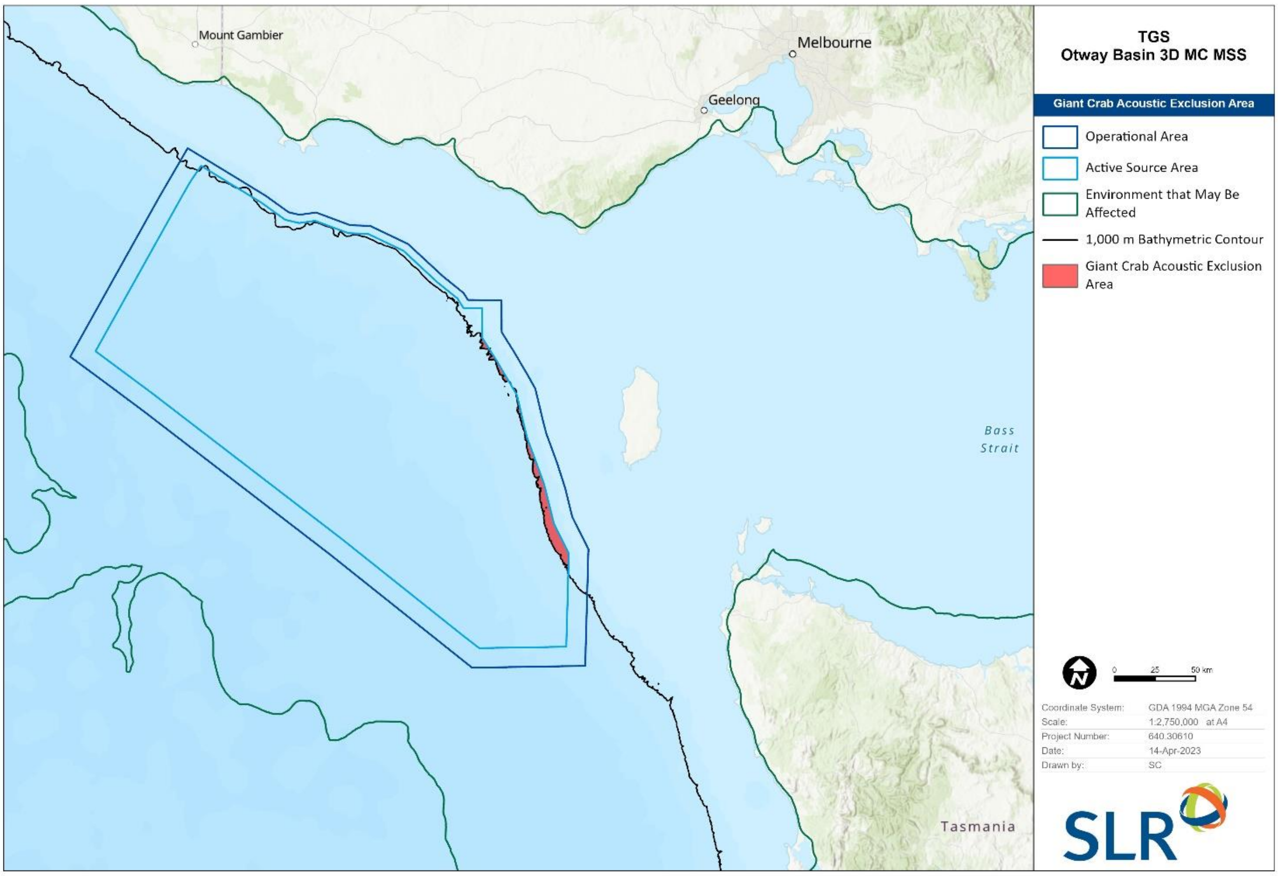

Figure 74 Giant Crab Acoustic Exclusion Area

7.1.3.1.3.3 Scalefish Fishery

Fishing effort within the TAS Scalefish Fishery focuses on the waters surrounding King Island. All blocks that overlap the AA were fished by >5 vessels per year for the period 2016 – 2020. The OA overlaps with one block that was fished by 5 – 10 vessels per year for the period 2016 – 2020 (**Figure 63**). The implementation of the Giant Crab Acoustic Exclusion Zone to protect the TAS Giant Crab Fishery is expected to also ensure interactions with vessels in the TAS Scalefish Fishery are avoided.

7.1.3.1.4 South Australian Fisheries

7.1.3.1.4.1 Rock Lobster Fishery

Fishing effort within the South Australian Rock Lobster Fishery primarily occurs in water depths up to 200 m. Although the OA and AA overlap with a fishing block with a high reported fishing effort (**Figure 64**), the precise location of fishing effort cannot be confirmed and it is likely that the deeper waters of the OA and AA are outside the main habitat for rock lobster and interactions with rock lobster vessels and pots are not expected.

7.1.3.1.4.2 Marine Scalefish

The South Australian Marine Scalefish Fishery primarily targets continental shelf species, and although the OA and AA overlap with a fishing block reported to have had a relatively high level of fishing effort in the period 2016 – 2020 (**Figure 66**), it is likely that the deeper waters of the OA and AA are outside the main areas targeted by this fishery.

7.1.3.1.5 Summary of Potential Impacts to Commercial Fisheries

Except for the 2D tie line AA (water depth 115 m, **Figure 4**), the AA covers water depths greater than 510 m and avoids areas of high fishing effort by many commercial fisheries. However, the northern and eastern boundaries of the AA and the OA still overlap with some fished areas on the upper continental slope and outer shelf.

The Otway Basin 3D MC MSS is a multi-client MSS and, as such, will acquire seismic data over discrete areas depending on petroleum titleholder interest over the full duration of the EP (see **Section 3.3**). Therefore, individual phases of the Otway Basin 3D MC MSS will target smaller and more discrete areas than the entire AA as the Seismic Vessel will only be operating in part of a 'Phase Operational Area' at any one time. Given that the exact location of individual phases cannot be defined at this stage, the assessment provided within this EP considers the potential extent of interference with each fishery as a worst case, noting that the extent may be significantly less.

The two fisheries with the greatest potential for interaction with the Seismic Vessel and towed equipment are the CTS and the SBTF (purse seine fishery and long line fishery).

Given the potential complexity of interactions with the SBTF and high catch value, some uncertainty remains regarding potential interactions with expanding long lining operations, however, given that a survey phase will occupy a discrete area and SBT are highly mobile throughout the region, alternative areas will be accessible outside of the survey phase area. Furthermore, the OA of the Otway Basin 3D MC MSS has been reduced, with the south-western boundary pulled back towards VIC waters and away from South Australian waters where the highest concentration of fishing within the SBTF occurs.

State managed giant crab fisheries typically target giant crab in water depths less than 400 m, but some fishing effort in deeper waters may occur. The 3D AA (generally deeper than 600 m) avoids the main area of fishing effort, although interactions with fishing in deeper waters may occur infrequently. A Giant Crab Acoustic Exclusion Area has been applied to water depths less than 1,000 m south of the 2D tie line AA which will ensure that interactions with vessels and pots in the TAS and VIC Giant Crab Fisheries are avoided. Acquisition of the 2D tie line has the potential for interactions with the VIC Giant Crab Fishery, although this tie line represents less than a day of survey effort and any interactions will be minimal. The Giant Crab Acoustic Exclusion Area also acts to minimise the potential for interactions with other fisheries (e.g. South Australian and VIC rock lobster fishers).

Fishing effort by other commercial fisheries is generally infrequent and of a low level such that movement of the Seismic Vessel and towed equipment along the most northerly and easterly margins of the OA are unlikely to result in a significant displacement of commercial fishers.

In the event that impacts to commercial fishing operations cannot be avoided, all evidence-based compensation claims made by commercial fishing licence holders for reduced catch or other costs incurred due to displacement by the Otway Basin 3D MC MSS, or for equipment damage/loss will be assessed for merit in accordance with the TGS Commercial Fisheries Compensation Protocol (see **Section 7.2.3.1** and **Appendix N**) which has been developed in accordance with the National Energy Resources Australia Collaborative Seismic Environment Plan Project – Commercial Fishing Industry Adjustment Protocol.

The Support Vessel/s will try to contact any vessel it sees in the exclusion area (i.e. the area identified within the 48-hour look ahead plans taking into consideration the vessel requested exclusion zone), and if there are traps remaining on the seabed (marked by surface buoys), the Support Vessel/s would try to contact the fishers whose gear is still in the water in the first instance to warn of the oncoming Seismic Vessel. In addition, to reduce the potential spatial overlap of fishing and data acquisition effort, TGS will provide any potentially affected commercial fishers with 48-hour look-ahead plans of where the survey vessels will be operating to enable them to incorporate the survey route into their fishing plans. This look-ahead will be updated and distributed every 24 hours. It is however, acknowledged that due to unforeseen circumstances, changes to where the Seismic Vessel may be required to traverse to acquire data may occur with limited notice to mariners making it difficult for commercial fishing operations to tightly coordinate fishing activities with planned vessel movements.

TGS acknowledges that consistent and timely communication on the location and timing of data acquisition activities is required to facilitate appropriate planning and to maximise the chance to share available spatial resources. Australian fishing licence holders that actively fish in the OA have been identified through the relevant persons consultation process and continual communications and notification (e.g. 48-hour look-ahead plans) will take place with these licence holders and their respective associations to ensure they are aware of where the vessel will be throughout the duration of the Otway Basin 3D MC MSS. Likewise, all methods of communication will be made available to the licence holders to contact the survey vessels should they need to be in contact with TGS or the survey vessels at any time.

Following consultation with commercial fisheries representatives, TGS will implement a fisheries compensation protocol to manage potential impacts from the Otway Basin 3D MC MSS including due to the presence of survey vessels and towed equipment on the commercial fishing industry in Australian waters. Further details of the proposed compensation protocol are provided in **Section 7.2.3** and **Appendix N**.

Any effects to commercial fisheries from the physical presence of the survey vessels and towed equipment are expected to be localised and only short-term disruptions to normal activities are expected. It is considered likely that the presence of the survey vessels and towed equipment will result in changes to commercial fishing operations to occur; however, with the implementation of the Commercial Fisheries Compensation Protocol, any claims of compensation due to changes will be assessed and compensation provided if required.

The physical presence of the Seismic Vessel and towed equipment are not predicted to impact key indicator commercial fish populations, thereby having negligible effect on the overall sustainability status of the fishery. As such, the residual risk to commercial fisheries due to the presence of the survey vessels and towed equipment during the Otway Basin 3D MC MSS has been assessed as **Low** (*Minor x Likely*).

7.1.3.2 Potential Impacts and Risks to Commercial Shipping

Frequent vessel traffic is expected to be encountered within the OA due to vessels heading in and out of Adelaide, Portland, Melbourne and Hobart, and vessels traversing the east-west/west-east shipping routes (**Section 4.7.4**).

Twenty-four-hour radar and visual watch and open radio communications between vessels will occur during the Otway Basin 3D MC MSS. Early communication allows for the speed and course of vessels to be ascertained in a timely manner and any necessary adjustment of course to be confirmed.

Some commercial vessels may need to deviate from their intended routes to avoid the Seismic Vessel and towed array. Vessel encounters that occur in line with the Seismic Vessel will involve a minor deviation of course to give way to the vessel, which would likely be similar to the deviation given to any other vessel transiting the region. Vessels that are sailing crossways to the survey sail line will need to deviate a greater distance. As the OA is in open waters with no grounding or navigational hazards, it is not likely that any such deviations would increase the potential for vessel collision or grounding in the area.

Commercial vessel masters are familiar with procedures for operating in the vicinity of a vessel restricted in its ability to manoeuvre and the survey vessels' masters and crews operate in areas of the world with significantly higher vessel traffic without significant issue. Therefore, no significant navigational implications or long-term changes in shipping traffic patterns are expected.

There is the potential that the Otway Basin 3D MC MSS could displace commercial vessels transiting through the OA causing them to alter their planned course. However, given the Seismic Vessel will be continually moving the actual zone of displacement that would influence commercial shipping will be transitory in nature. Therefore, the risk to commercial shipping operations due to the physical presence of the survey vessels and towed equipment during the Otway Basin 3D MC MSS has been assessed as **Low** (*Minor* x *Likely*).

7.1.3.3 Potential Impacts and Risks to Tourism and Recreation

The coastal marine area inshore of the OA and EMBA provide opportunities for marine tourism and recreational activities such as boating, diving, surfing, and fishing. Given the water depths within the OA (97 – 5,000 m), distance from shore (31 km to the closest point on the mainland), and exposed and changeable sea and weather conditions, the OA does not provide many opportunities for tourism and recreation activities. Despite these limitations, there is still potential for activities associated with the Otway Basin 3D MC MSS to displace other marine users from their preferred areas of activity, in particular recreational fishers and boating.

Recreational boating activities peak during the summer months, and this increase in activity is likely to occur inshore of the OA. Recreational boaters and tourism operators tend to utilise the waters surrounding major ports and settlements, such as the sheltered waters of Port Phillip Bay (VIC) and the relatively inshore waters of the Spencer Gulf and Gulf of St Vincent (South Australia). The Otway Basin 3D MC MSS is proposed to occur between October and March (**Section 3.3**) so it is likely there will be a large number of recreational and tourism boats out on the water; however, most of these boats are likely to be well inshore of the Otway Basin 3D MC MSS OA.

The scheduling of the Otway basin 3D MC MSS overlaps with the recreational open seasons for diving for abalone and rock lobster, and fishing for squid, striped trumpeter, prawns, and banded morwong. The presence of the Seismic Vessel will not displace recreational divers from their dive site or from fishing areas due to the considerable distance offshore of the OA.

The Melbourne to Hobart (Westcoaster) yacht race follows the west coast of TAS and has the potential to overlap (both temporally and spatially) with the Otway Basin 3DMC MSS. The race occurs over two days in late December. Races run by the Ocean Racing Club of VIC at Christmas also utilise the west and south coasts of TAS and may overlap (both temporally and spatially) with the Otway Basin 3DMC MSS. TGS has undertaken consultation with Ocean Racing Club of VIC to appropriately manage any overlap between the Otway Basin 3D MC MSS and yacht racers to ensure there is no risk of overlap between Survey Vessels and competitors or increased risk of a collision.

To manage any potential risk to tourism and recreational users of the OA, TGS has consulted with key industry representative bodies, will issue maritime warnings and a Notice to Mariners effective for the duration of the Otway Basin 3D MC MSS, and maintain standard maritime radio communications.

The intermittent and transitory nature of the Seismic Vessel operating within the OA is thought to present minimal displacement or inconvenience to tourism and recreation in the area. Therefore, the residual risk to tourism and recreation due to the physical presence of the survey vessels and towed equipment during the Otway Basin 3D MC MSS has been assessed as **Negligible** (*Negligible x Unlikely*).

7.1.3.4 Potential Impacts and Risks to Petroleum Exploration and Production Operations

The Otway Basin is an established hydrocarbon province in Australia, with several commercial operations within the area (**Section 4.7.5**). Vessels associated with nearby petroleum operations may be asked to deviate from intended routes to avoid the Seismic Vessel and towed equipment. However, this is unlikely on account of all currently operating oil and gas facilities (for example, the Thylacine platform) occurring inshore of the OA (see **Figure 68**).

Although it is not anticipated that the survey vessels will need to transit near any petroleum exploration and production operations, all vessels will adhere to the prohibition of vessel entry into designated petroleum safety zones and surrounding petroleum wells, structures, or equipment.

TGS will work collaboratively with petroleum operators to ensure interactions offshore are minimised and has consulted with petroleum holders throughout the development of this EP, with consultation continuing for the life of this EP. Should the Otway Basin 3D MC MSS be undertaken during operations which overlap with oil and gas operations (e.g. commercial diving operations on underwater infrastructure), a SIMOPS plan will be developed in close collaboration with the relevant persons.

The intermittent and transitory nature of the Seismic Survey Vessel operating within the OA is thought to present minimal displacement or inconvenience to petroleum exploration and production operations in the area. Therefore, the residual risk to petroleum and production operations due to the physical presence of the survey vessels and towed equipment during the Otway Basin 3D MC MSS has been assessed as **Low** (*Minor* x *Unlikely*).

7.1.4 Decision Context

The decision context for physical presence of the Seismic Vessel and towed equipment has been assessed as Type A for most receptors, given the predicted impacts and risks are well understood and uncertainty is minimal, with little or no interest from relevant persons. However, given the level of interest raised by relevant persons regarding predicted impacts to commercial fisheries, the decision context for this receptor has been characterised as Type B.

7.1.5 Identification of Control Measures, Residual Risk Assessment and Demonstration of ALARP

Control/mitigation measures that will be implemented during the Otway Basin 3D MC MSS to manage the impacts associated with the physical presence of the Seismic Vessel and towed acoustic equipment to **ALARP** have been listed in **Table 57**. TGS has considered a number of control measures to determine the benefits of their implementation towards risk reduction (**Table 57**), based on a Hierarchy of Controls methodology (**Table 56**). The control measures that will be adopted are those that have been assessed and characterised as effective and practicable to implement.

Table 56 Hierarchy of Control Measures for Physical Presence of the Seismic Vessel and Towed Equipment

Eliminate	Alternative data acquisition methods are not yet commercially available or proven to meet geophysical data quality objectives, operational safety, and reliability requirements. The Seismic Vessel and towed equipment are, therefore, required for data acquisition and cannot be eliminated. The presence of a Support Vessel/s is a health and safety requirement which acts to reduce the risk of collision between the Seismic Vessel/towed equipment and other marine users and/or entanglement between marine fauna/fishing gear and seismic equipment.
Substitute	Alternative data acquisition methods are not yet commercially available or proven to meet geophysical data quality objectives, operational safety, and reliability requirements. The Seismic Vessel and towed equipment have been designed to meet the survey objectives and guarantee data quality. Due to the transient nature of the survey, the cost of substituting the equipment (e.g. to adopt the use of shorter streamers) are considered disproportionate to the limited (if any) environmental benefits gained.
Reduce	The impact from the physical presence of the Seismic Vessel and towed equipment will be reduced by the implementation of the control measures described within **Table 57.** Streamers will be marked with tail buoys to notify other marine users of the presence of the towed equipment and reduce the risk of collision.
Mitigate	To mitigate the impacts from the physical presence of the Seismic Vessel and towed equipment, a compensation protocol will be implemented to formally manage claims by commercial fishers for loss of catch, displacement, and/or lost or damaged fishing gear as a consequence of the Otway Basin 3D MC MSS (**Section 7.2.3.1**).

Table 57 Assessment of Control Measures for the Physical Presence of Seismic Vessel and Towed Equipment

Control measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Legislative Requirements:			
The Otway Basin 3D MC MSS will be undertaken in accordance with the approved EP.	P = Yes E = Effective	All vessels undertaking an offshore activity in waters between 3 and 200 NM must undertake that activity in line with an approved EP. The approved EP outlines the measures that will be taken to ensure that environmental effects from the activity will be reduced to **ALARP** and **Acceptable Levels**, including the management of routine permissible waste discharges.	Yes
All survey vessels will adhere to the requirements of the national and international legislation, including COLREGS and Chapter 5 of SOLAS as implemented in Commonwealth Waters through the *Navigation Act 2012* and associated Marine Orders 21, 28, 30, 58 and the STCW Convention. The requirements give effect, but are not limited to, the following: • Appropriate use of lighting, navigation and radio communication at sea; and • 24-hour bridge and radar watch by qualified watch-keepers to monitor for other marine users.	P = Yes E = Effective	The survey vessels must adhere to the Navigation Act 2012 and associated Marine Orders. Procedures under the Navigation Act 2012 are standard and well-understood among commercial vessels. The survey vessels will use standard international safety procedures for radio communication and the display of navigational lights and day shapes including the use of Automatic Radar Plotting Aids (**ARPA**) and AIS. AIS sends and receives ship information including identity, position, course, and speed, and updates as often as every two seconds. The Seismic Vessel will display day shapes and lights to indicate that the vessel is towing equipment and is restricted in its ability to manoeuvre. Tail buoys will be fitted with a light and radar reflector indicating the end of each streamer. The survey vessels will use standard international safety procedures for radio to ensure survey vessels will be contactable by radio at all times (i.e. VHF and SSB radio). The Otway Basin 3D MC MSS will adopt standard flag and class practices for watch-keeping and radio use to ensure that warnings and preventative actions can be readily implemented. This will notify other marine users of the presence of the Seismic Vessel and equipment. Watch-keepers will have the relevant qualifications for the task. This practise is compliant with STCW Convention. It is a legislative requirement for vessels to comply with the Navigation Act 2021 as well as good industry practice.	Yes
Adherence to the prohibition of entry into established Petroleum Safety Zones surrounding petroleum wells, structures, or equipment.	P = Yes E= Effective	Oil and gas installations and equipment have established Petroleum Safety Zones (**PSZ**) prohibiting any vessel approaching closer than 500 m without prior approval/provision of a permit. These are established under the OPGGS Act. A review of the gazetted notices for Petroleum or Greenhouse Gas Safety Zones published on NOPSEMA's website indicate the OA does not encroach into any PSZ. It is a legislative requirement.	Yes
Vessel masters' of the Support Vessel/s will comply, when safe to do so, with the relevant requirements of EPBC Regulations 2000 Part 8, Division 8.1, including: • Taking action to avoid approaching or drifting closer than 50 m to an adult dolphin or 100 m to an adult whale; • Taking action to avoid approaching or drifting closer than 150 m to a dolphin calf or 300 m to a whale calf; • Making all efforts not to let a calf enter the caution zone; and • Not exceeding a speed of six knots within the caution zone of a cetacean (300 m).	P = Yes E = Effective	The requirements of the EPBC Regulations set out clear measures to reduce speed and avoid approaching cetaceans, which reduces the risk of collision or entanglement. The support vessels will comply with the EPBC Regulations 2000 Part 8, Division 8.1 in order to reduce the risk of disturbing cetaceans (adult and calf) and avoiding collisions between a cetacean and the support vessels. For safety reasons, the distance requirements are not applied to vessels with limited manoeuvrability, such as the Seismic Vessel It is a legislative requirement for vessels to comply with the EPBC Act and EPBC Regulations.	Yes
Any vessel strike incident to marine mammals will be reported as soon as practicable via the National Vessel Strike Database within 72 hours of the incident.	P = Yes E= Effective	Reporting ship strikes with cetaceans is requested by the DAWE's Australian Antarctic Division and allows the Australian Government and International Whaling Commission (**IWC**) to compile scientific data on vessel strike incidents, locations and trends so that further management can be considered. Good industry practice, environmental benefit outweighs additional cost.	Yes

Control measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Good Industry Practice:			
A communications protocol will be in place between the survey vessels and other relevant persons (e.g. commercial fishers known to utilise the OA, oil and gas operators), to actively manage concurrent activities.	P = Yes E =Effective	A communications protocol will be in place which details the methods used to contact third-party vessels prior to commencement of the Seismic Survey, throughout the survey duration, and following completion of the survey, and those identified only once at sea, to actively manage concurrent activities. Communication with relevant persons allows those potentially affected by the Otway Basin 3D MC MSS to plan activities in a manner that reduces the risk of interactions with the survey vessels and towed equipment (e.g. commercial fishers can avoid deploying gear in the path of the Seismic Vessel). TGS will provide a daily 'look-ahead' plan, which details the proposed operations for the next 48-hour period. Information regarding proposed operations will include, as a minimum, the current positions of the survey vessels and the proposed timing and location of operations for the following 48 hour period. These will be provided daily to those relevant persons who register for the service. Good industry practice, safety benefit outweighs additional cost.	Yes
Notification to the Australian Hydrographic Office (**AHO**) for the publication of a Notice to Mariners of survey presence and towed array, no less than four weeks before operations commence.	P = Yes E = Effective	Under the Navigation Act 2012, AHO can publish and distribute a Notice to Mariners. This Notice outlines potential hazards and restrictions to relevant persons. AHO will be contacted four weeks prior to the commencement of the survey for the publication of related Notices to Mariners. Good industry practice, safety and socio-economic benefit outweighs additional cost.	Yes
Notification to the Joint Rescue Coordination Centre (**JRCC**) for the promulgation of navigational warnings (i.e AUSCOAST warnings)	P = Yes E = Effective	The JRCC will be contacted 24 – 48 hours before operations commence for issuing of radio-navigation warnings. This will ensure that commercial fishers are aware of the Otway Basin 3D MC MSS. Implementation will reduce the likelihood of interactions with commercial fishing vessels. Good industry practice, safety benefit outweighs additional cost.	Yes
At least one Support Vessel will accompany the Seismic Vessel when in operation and when safe to do so (e.g. outside of inclement weather periods), to manage interactions with other marine users.	P = Yes E = Effective	At least one support vessel will be present around the Seismic Vessel to intercept other vessels in the area that are at risk of interacting with the Seismic Vessel and/or equipment and to ensure other marine users in the area are provided with advanced notice of the Otway Basin 3D MC MSS. This is a health and safety requirement and is standard practice for all MSSs. Good industry practice, safety benefit outweighs additional cost.	Yes

Control measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Compensation to fishers and vessel crews (i.e., the claimant) is demonstrated to have occurred for the following circumstances: • Interaction resulting in loss or damage to fishing equipment; • A temporary loss of fish landed catch due to damaged or lost fishing equipment; • Where displacement from fishing grounds results in additional costs incurred due to relocating; or • A temporary reduction in fish landed catch due to the effects of acoustic emissions or displacement from fishing grounds. Claims received from fishers in any circumstances other than those outlined above will not be assessed. Claims will be considered provided the interaction/displacement/loss of catch took place in the Adjustment Area (plus any additional area of avoidance requested around the survey vessels and towed equipment) where the Otway Basin 3D MC MSS took place, and within the project active time frame only.	P = Yes E = Effective	Where impacts of the Otway Basin 3D MC MSS to the commercial fishing industry in Australian waters cannot be avoided or minimised, and commercial fishers experience an economic loss as a result of the Otway Basin 3D MC MSS, financial compensation will be considered as a potential appropriate response to eligible fishery licence holders. Compensation to commercial fishers for loss or damage to fishing equipment, a temporary loss of fish landed catch due to damaged or lost fishing equipment, where displacement from fishing grounds results in additional costs incurred due to relocating, or a temporary reduction in fish landed catch due to effects of acoustic emissions of displacement from fishing grounds that is proven to have occurred as a result of the Otway Basin 3D MC MSS will be considered on a case-by-case basis. Claims received from fishers in any circumstance other than these will not be assessed. Displacement from fishing grounds can be as a result of seismic operational activities and/or as a result of avoiding contaminated waters following a fuel oil spill. For TGS to accept a payment claim, fishers will need to provide suitable documented evidence and data to demonstrate their unavoidable economic loss in accordance with the Commercial Fisheries Compensation Protocol for the Otway Basin 3D MC MSS (**Section 7.2.3.1**). All fishing history and unavoidable economic losses should relate to the Adjustment Area and to the period of Otway MSS operations. The Adjustment Area is defined as an area extending 10 km around the perimeter of the OA. Any consideration of claims (for claims for temporary reduction in catch due to displacement from fishing grounds) beyond the Adjustment Area and outside the operations period will be determined with reference to available and relevant peer reviewed information on the effects of seismic surveys, as well as the impact assessment outlined in the EP as accepted by NOPSEMA. To be eligible for compensation, claimants are required to provide initial notification of their intent to submit a claim to TGS within 30 days of equipment being damaged or lost, and/or being displaced from 'usual fishing grounds' (defined as an area where fishing activity has been recorded by the commercial fishing licence holder on Government statutory fishing returns for at least two of the previous five years). For displacement claims only, licence holders or vessels are to notify TGS at the time of relocation for claims to be valid. A completed Compensation Claim Application Form must be submitted to TGS within 12 months of notifying TGS of the intention to submit a claim. In assessing the merit of the claim, consideration will be given to the circumstances giving rise to the claim, including whether the circumstances could have been reasonably avoided. Subject to a claim being lodged, TGS (at their expense) in consultation with the claimant, will engage a suitably experienced/qualified independent person/organisation as the assessor of the claim, defined as a person or organisation with proven demonstrated experience in data analysis and data auditing processes and procedures within the industry. The assessor will provide TGS with an assessment report, which, upon receiving and considering this report, TGS will provide to the claimant and offer to meet to discuss and address the claim. If a claimant disagrees with the claim assessment outcome and cannot reach agreement with TGS, they may, within 30 days, opt to request a suitably experienced and qualified independent third-party to review and determine the outcome of the claim. This appointment will be mutually agreed between TGS and the claimant. The dispute will be resolved within 60 days of dispute receipt by TGS, with the costs of engaging the independent third-party covered by TGS. Good industry practice, socio-economic benefits outweigh additional cost.	Yes

Control measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Development and implementation of Marine Fauna Mitigation Plan. Where possible and safe to do so, marine fauna entangled within in-water equipment will be extricated and returned to sea following the procedures provided within the Marine Fauna Mitigation Plan.	P = Yes E = Effective	One of the roles of the lead MFO is to develop a Marine Fauna Mitigation Plan, to be submitted to TGS prior to the pre-mobilisation survey and audit commencing. This plan will demonstrate the following, at a minimum: • MFOs are trained, dedicated and experienced (as per the requirements listed in **Section 10.3.5**); • Responsibilities and authorities of MFOs to ensure the plan is communicated and available to those roles that are required to implement the controls; • Communications protocols for relaying marine fauna observations to the Seismic Operator, Vessel Master and vessel crew as required; • Survey Plan – describes the proposed activity including location and timing, acoustic source and streamer configuration, equipment (vessels) and key geographic locations such as BIAs and nominated exclusion zones; • Implementation Plan – details how the marine fauna mitigation controls within the EP will be implemented; and • Handling procedures for the retrieval of marine fauna entangled in towed equipment or seabirds on the vessels' deck. Good industry practice, environmental benefit outweighs additional cost.	Yes
Vessel crew will complete an environmental induction covering the requirements for vessel interactions with marine fauna.	P = Yes E = Effective	Environmental inductions will be included as part of the crew induction package, including requirements for vessel interaction managed with marine fauna, consistent with the controls described within the accepted EP. Good industry practice, environmental benefit outweighs additional cost.	Yes
Streamers will be marked with tail buoys.	P = Yes E = Effective	Under COLREGS and the Navigation Act, all possible measures need to be taken to indicate the presence of a towed object. Tail buoys will be used to mark the ends of the streamers, so that they are visible to other vessels. Markings on the tail buoys will include reflective tape, lights, and radar reflector. An AIS transponder will also be fitted to each tail buoy to allow for the detection of the end of each streamer by other marine users with AIS receiving capabilities. Good industry practice, safety benefit outweighs additional cost.	Yes
Turtle guards will be installed on streamer tail buoys or tail buoys will be of a design that does not represent an entrapment risk to marine turtles.	P = Yes E = Effective	Almost all reported turtle entrapments during MSSs are associated with the 'undercarriage' of tail buoys (Ketos Ecology, 2009). 'Turtle guards' are fitted to the front of the tail buoys and act to physically exclude turtles from the gap at the front of the tail buoy undercarriage. A tail buoy will be fitted to the end of each streamer. If the tail buoys are not of a design that does not represent an entrapment risk to marine turtles, they will be fitted with turtle guards to prevent accidental entrapment. Good industry practice, environmental benefit outweighs additional cost.	Yes
Vessels masters' of the support vessel/s will, when safe to do so, take action to avoid approaching or drifting closer than 50 m to a marine turtle or pinniped.	P = Yes E = Effective	The Australian sea lion, Australian fur seal, and the New Zealand fur seal (**Section 4.5.6.3**), as well as three species of marine turtle (**Section 4.5.5**) have been identified as potentially present within the OA. In addition to implementing the avoidance measures required for cetaceans under the EPBC Regulations 2000 Part 8, Division 8.1, TGS has considered extending avoidance measures to marine turtles and pinnipeds. For safety reasons, the distance requirements are not applied to vessels with limited manoeuvrability, such as the Seismic Vessel. Good industry practice, environmental benefit outweighs any additional cost.	Yes

Control measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Alternatives/Substitutes Controls Considered:			
Use of alternative geological imaging technology that does not require towed equipment.	P = No E = Unknown Effectiveness	To further reduce the potential for entanglement, an alternative to the use of towed streamers is the use of ocean bottom receivers; however, this was considered impractical for the following reasons: • Environmentally, ocean bottom receivers placed on the seabed may reduce the risk of marine fauna becoming entangled in towed streamers, however, ocean bottom receivers can result in unnecessary seabed disturbance particularly in sensitive areas; • Operationally, this alternative would add significantly to the cost and timeframe for the survey. Ocean bottom receivers cover much less acreage per day than towed streamer methods ; • Given that there have been no reported cases of marine fauna being entangled in seismic equipment in the Otway Basin, the risk is already very low and little additional benefit would be gained. Costs would be disproportionate to the benefit that may be gained.	No
Removal of support vessels.	P = No E = Limited	Support vessels are required to avoid interactions with other marine users (i.e. other vessels) as a health and safety requirement as well as implementing the control measures. Increased risks associated with the removal of the support vessels are disproportionately higher than the benefit of removing a vessel.	No
Reduction in the length of the towed equipment.	P = No E = Limited	The length of the streamers planned to be used for the Otway Basin 3D MC MSS is 8 – 10 km. Streamer length has been designed to meet the survey objectives and guarantee data quality. Reducing the length of the towed equipment, or substituting with shorter streamers, will reduce the footprint of the Otway Basin 3D MC MSS; however, as the vessel and towed equipment are continuously moving, the benefit to other marine users would be minimal and costs would be disproportionate to any benefit gained.	No
Additional Control Measures Considered			
Towed equipment will be retrieved when the Seismic Vessel is in transit to and from the OA (e.g. to and from port).	P = No E =Effective	Retrieval of towed equipment would reduce the potential for more coastal species interacting with the towed equipment whilst in transit and will minimise the spatial footprint of the Seismic Vessel when transiting; however, the Seismic Vessel may on occasion be required to exit the OA without retrieving the towed equipment, such as during periods of inclement weather. Not practicable to implement.	No
The acoustic source will only be deployed and retrieved within the bounds of the OA.	P = Yes E = Effective	As outlined above, there may be occasions during the Otway Basin 3D MC MSS whereby the vessel may be required to exit the OA while towed equipment remains deployed. In order to ensure there is no accidental discharge of the acoustic source outside of the boundaries of the OA, the acoustic source will only be deployed and retrieved in the OA.	Yes
Retrieval of any equipment accidentally lost at sea, including streamers, where it is safe and practicable to do so to ensure it does not become a risk to other marine users. Pressure activated streamer recovery devices will be fitted along the streamers.	P = Yes E =Effective	Any in-water equipment that is lost will be recovered when it is safe and practicable to do so. Pressure activated streamer recovery devices will be fitted along the streamers. Where equipment cannot be safely or practicably retrieved, the incident will be reported to AMSA and AHO as soon as the loss/incident is identified. Good industry practice, safety and environmental benefit outweighs additional cost.	Yes
Access to Seismic Vessel tracking information via Google Earth for fisheries relevant persons who have registered for the service.	P = Yes E =Effective	TGS will provide commercial fishers with access to Seismic Vessel tracking information via Google Earth. This will ensure that commercial fishers are aware of the exact location of the Seismic Vessel in real time. Implementation of this control measure will reduce the likelihood of interactions with commercial fishers.	Yes

Control measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Giant Crab Acoustic Exclusion Area within waters 1,000 m or less south of the 2D tie line AA.	P = Yes E = Effective	TGS will adopt an Acoustic Exclusion Area over water depths shallower than 1,000 m to the south of the 2D Tie Line AA. This protects giant crab habitat but also areas where giant crab fishing effort in the TAS Giant Crab Fishery may occur. The control also indirectly reduces overlap with giant crab habitat and fishing grounds in the VIC Giant Crab Fishery.	Yes
Manage impacts to the SBTF through the implementation of a SBT Assessment Area for waters offshore from South Australia, and a joint risk assessment with the SBTF.	P = Yes E = Effective	Following consultation with SBTF representatives (i.e. ASBTIA), in order to provide a mechanism to simultaneous operations with the SBTF, TGS designated all waters in the OA from South Australia as a SBT Assessment Area. This area was proposed to manage the potential risk to both SBT behaviour during SBT fishing and towing operations, and also to divers involved in fishing operations. When seismic acquisition is planned to occur within the SBT Assessment Area, TGS proposed to: • Notify ASBTIA of the proposed survey activities at least four weeks prior to the commencement of survey activities; • Conduct a joint risk assessment with ASBTIA and share vessel contact details prior to commencement of survey activities; • During seismic acquisition, maintain direct communication between the seismic vessel and SBT fishing and tow vessels; • As the vessel approaches areas of SBT fishing or towing activities, stand-off and implement adaptive management measures, as agreed in the joint risk assessment; and • Have MFOs record the locations of any SBT at the surface and communicate co-ordinates to SBT fishing and tow vessels and ASBITA. The above approach was intended to find an amicable approach to managing simultaneous operations that allows both industries to conduct their operations while the seismic vessel approaches; however, following subsequent consultation with relevant persons, the OA was revised and the waters offshore from South Australia that were to be designated as the SBT Assessment Area were removed. The implementation of a SBT Assessment Area is therefore no longer required, however, ASBTIA will still be notified of the proposed survey activities at least four weeks prior to commencement of the survey under the required four-week notification as per the Communications Protocol, all survey vessels will be contactable at all times by other marine users (including SBT fishers) via radio communications (as per the requirements of COLREGS and Chapter 5 of SOLAS as implemented in Commonwealth Waters through the *Navigation Act 2012* and associated Marine Orders 21, 28, 30, 58 and the STCW Convention), and the Seismic Vessel will consider alternative lines, where practicable following receipt of information from commercial fishers (including SBT fishers) on upcoming fishing activities. MFO on the survey vessels and during aerial surveys will be instructed to remain vigilant for SBT at the surface, with observations reported to ASBTIA (see control measure below).	Partially

Control measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Adjustment of sail lines to accommodate commercial fishers' requests.	P = No E = Limited	As discussed in **Section 4.7.3**, there is limited overlap with the Otway Basin 3D MC MSS and heavily targeted areas by commercial fishers on account of the deep water depths throughout the OA. This reduces the likelihood of there being impacts to commercial fishers from the physical presence of the Seismic Vessel and towed equipment. All survey vessels contracted for the Otway Basin 3D MC MSS will be contactable at all times throughout the duration of the survey. Survey lines have been pre-planned to allow accurate data acquisition and to ensure the survey is completed in the most economic way. The planned movements of the Seismic Vessel for the upcoming 48-hour will be provided to relevant persons who opt into the service, therefore allowing fishers to plan their voyages and avoid any interaction with the Seismic Vessel and towed equipment. Furthermore, if a commercial fisher does experience economic loss as a result of the Otway Basin 3D MC MSS, they may submit a compensation claim under the Commercial Fisheries Compensation Protocol, with this claim assessed by an independent third-party assessor. The potentially significant action of adjusting survey lines to accommodate commercial fishers greatly outweighs the limited potential benefit gained.	No
No seismic acquisition during the peak juvenile southern bluefin tuna migration and the timing of most SBTF (purse seine) operations (December to April).	P = No E = Limited	December to March represents a period when weather and sea conditions are likely to be favourable to seismic acquisition. Based on the weather and sea state analysis, seismic acquisition is most likely to be possible from October to March, with December to March the most favourable and periods outside of this potentially having too much weather downtime. The period when pygmy blue whales may be foraging in the region also occurs in the summer months and there is the possibility that controls to avoid disturbing and displacing this species could also indirectly limit acquisition during the same months as the tuna migration. However, the timing of both southern bluefin tuna and pygmy blue whales are seasonally variable and excluding acquisition may unnecessarily exclude months when they are not actually present in the region. Excluding acquisition between December and March could mean that it is not possible to complete a survey phase. Seismic surveys have previously been undertaken near the continental shelf break in the Otway region and the GAB at the same time as fishing for southern bluefin tuna; both activities have been able to proceed noting from TGSs previous experience that they are typically able take place in different locations from one another. Over the last 10 – 11 years, large-scale seismic surveys have been undertaken in these regions at the same time as an upward trend in total allowable catch and steady or increasing catch rates in both the purse seine and east coast long line fisheries, suggesting no apparent disruption to juvenile southern bluefin tuna migration. The potentially significant cost of excluding December to April to the survey greatly outweighs the limited potential benefit gained.	No

Control measure	Practicability/ Effectiveness	Justification	Will it be adopted?
No seismic acquisition from April to December to avoid interactions with fishers in the ETBF.	P = No E = Limited	During stakeholder consultation, the industry association, Tuna Australia, identified the potential future increase in longline effort in the ETBF in waters off VIC and TAS. Southern bluefin tuna are caught by the ETBF under the same quota as the purse seine sector of the fishery that typically operates of South Australia. ETBF boats also target southern bluefin tuna during the winter months when the adult fish become available to the longline method. The amount caught is dependent on the available quota after the purse seine sector has finished its catching season. Tuna Australia requested that the Otway Basin 3D MC MSS avoid the period April to December to avoid impacts to long line fishers in the ETBF. This period is the opposite of the period fished for juveniles by the purse seine sector. It is likely that winter months will already involve significant periods of downtime due to unfavourable weather and sea states. However, exclusion of the period April to December also risks months when conditions are favourable for survey activities. Excluding these months may mean that it is not possible for a survey phase to be completed or even to proceed. Seismic surveys have previously been undertaken near the continental shelf break in the Otway region and the GAB at the same time as fishing for southern bluefin tuna; both activities have been able to proceed noting from TGS previous experience that they are typically able take place in different locations from one another. It is noted that survey and future long lining could target similar areas at the same time of year. TGS will communicate with fishers throughout any survey phase and, where practicable, will avoid areas of fishing activity. However, excluding the period April to December is not considered practicable.	No
Daily contact with relevant persons to update on survey plans.	P = No E = Effective	It would not be possible to contact all relevant persons on a daily basis, particularly recreational users. If requested, relevant persons will be notified every 24 hours with the 48-hour look-ahead of vessel movements, a Notice to Mariners will be in place throughout the duration of the Otway Basin 3D MC MSS, and the survey vessels will be contactable on marine radio.	No
Seismic acquisition will only occur outside of fishing seasons.	P = No E = Effective	As there will be some commercial fishing activities year-round (see **Table 37**), TGS are unable to operate outside of all fishing seasons.	No
Vessel master of the Seismic Vessel will take evasive action to avoid marine fauna and other marine users.	P = No E = Ineffective	The Seismic Vessel has limited ability to manoeuvre. It is unlikely any attempt to avoid a collision will have the desired result. The Seismic Vessel will instead maintain a constant speed and will not deviate from survey lines with the exception of line turns.	No
Seismic acquisition will only occur during daylight hours to allow for visual identification of the Seismic Vessel and towed equipment.	P = No E = Limited	24/7 operations will occur to minimise the duration of the survey. This measure would result in significant extensions to the time required to acquire survey data. Interactions between the Seismic Vessel and other marine users could still potentially occur during daylight hours. The vessels associated with the Otway Basin 3D MC MSS will display the appropriate navigation lights and will use ARPA and AIS for identification to other vessels. Vessels will be contactable through radio-communications at all times. The towed equipment will be visually identifiable through display of lights, radar reflectors and use of AIS transponder on the tail buoys to mark the end of all the streamers. Costs would be disproportionate to the benefit gained.	No
No seismic acquisition within major shipping routes.	P = No E = Limited	Major commercial shipping routes are generally based on a direct line from major ports, and it has been shown that there is some overlap with the OA. Avoiding these shipping routes would result in very large data gaps meaning that the Otway Basin 3D MC MSS would not meet survey objectives. Numerous control measures will be implemented during the Otway Basin 3D MC MSS, such as the use of AIS and radar on the Seismic Vessel and towed equipment, broadcasting of Notices to Mariners, and radio contact with Seismic Vessel will reduce the likelihood of any interactions with commercial vessels. These measures are considered sufficient to manage vessel interactions. Commercial vessels are able to plot courses and manoeuvre themselves to avoid the Seismic Vessel without compromising their overall transit times, especially with the advanced notification they will receive. Costs would be disproportionate to the benefit that may be gained.	No

Control measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Use of additional support vessels to further reduce the potential for collision or interference with other marine users.	P = No E = Limited	The use of additional support vessels may minimise interactions with other marine users as it allows for communication and management of interactions if there is an interaction with more than one approaching vessel. However, the use of additional support vessels adds increased risk to marine mammals as the additional vessels in the water pose a further collision risk. The use of additional support vessels would result in significant costs that would be detrimental to the commerciality of the survey. Costs would be disproportionate to the benefit to other marine users that is gained, and also would increase risk to marine fauna.	No
Residual Risk of Impact (Receptor)	**Consequence**	**Likelihood**	**Residual Risk Ranking**
Marine Reptiles	Minor	Unlikely	Low
Marine Mammals	Minor	Unlikely	Low
Seabirds	Minor	Unlikely	Low
Commercial Fisheries	Minor	Likely	Low
Commercial Shipping	Minor	Likely	Low
Tourism and Recreation	Negligible	Unlikely	Negligible
Petroleum Exploration and Production Operations	Minor	Unlikely	Low
ALARP Statement			
The decision context has been assessed as Type B and the overall residual risk has been determined to be Negligible to Low. TGS considers the adopted control measures minimise the risk of impacts from the presence of the Seismic Vessel and towed equipment and are appropriate to the localised nature and small scale of the predicted environmental impacts associated with the Otway Basin 3D MC MSS. The proposed control measures have been developed in accordance with the legislative requirements, good industry practice, using professional experience and considering the specific environmental, social, economic and cultural characteristics of the OA and predicted impacts to other marine users. Additional control measures were considered as part of the assessment process; however, it was considered that they did not provide any further environmental benefit or were not reasonably practicable to implement. Therefore, the predicted impacts to receptors from the physical presence of the Seismic Vessel and towed equipment are reduced to **ALARP.**			

7.1.6 Impact and Risk Acceptability

Table 58 Demonstration of General Impact and Risk Acceptability for Physical Presence of Seismic Vessel and Towed Equipment

Criteria for Acceptance	Acceptability Summary
Residual Risk Ranking	The residual risk has been determined to range from **Negligible** to **Low**.
Ecologically Sustainable Development	The management of the impacts associated with the presence of the Seismic Vessel and towed equipment proposed by TGS can be carried out in compliance with principles of ESD as defined within the EPBC Act. There is no threat of serious or irreversible environmental damage or significant impact to biological diversity and ecological integrity associated with disruption/interference with other users during the Otway Basin 3D MC MSS. Therefore, the impact is considered to be consistent with the principles of ESD.
TGS Internal Context	The proposed management of the risks associated with the establishment of IMS is consistent with TGSs QHSE Policy commitments of: • Protecting the environment; and • Conducting operations in an environmentally sustainable and responsible manner.
Existing Environmental Context	It is considered that the physical presence of the Seismic Vessel and towed equipment will not result in any significant impact on environmental values or sensitivities within the OA, including protected species such as marine mammals, marine turtles, and seabirds. The OA overlaps BIAs for the following species which may be affected by the physical presence of the survey vessels and towed equipment: pygmy blue whale, southern right whale, wedge-tailed shearwater, short-tailed shearwater, wandering albatross, Antipodean albatross, Australasian gannet, white-faced storm-petrel, common diving-petrel, Bullers albatross, shy albatross, Indian yellow-nosed albatross, black-browed albatross, and Campbell albatross. Other protected species have been identified as potentially present within the OA but do not have a BIA that overlaps with the boundaries of the OA. The potential impacts from the physical presence of the survey vessels and towed equipment will be of similar nature and scale to commercial vessels which traverse or utilise (e.g. commercial fishing vessels). Notably, the OA already experiences a high level of shipping traffic and the Otway region has been subject to previous MSSs. The Seismic Vessel will be transit at a speed of 4.5 knots along predetermined sail lines, meaning that there is the capacity for relevant persons to plan around the activity where consultation has occurred, and notification provided. The predicted impacts to the identified environmental receptors are considered to be minor and short-term, and managed through the implementation of control measures such as temporal and spatial exclusions around marine mammal BIAs and compliance with relevant legislation around vessel approach when in the presence of marine mammals. The impacts to commercial fishers are considered to be managed through the implementation of TGSs Commercial Fisheries Compensation Protocol, and the extensive consultation programme which includes communication with relevant persons for the life of the Otway Basin 3D MC MSS.
External Context – Management Plans, Species Recovery Plans and Conservation Advice	The residual risk of the physical presence of the Seismic Vessel and towed equipment has been determined to range between Low to Moderate and will not have a significant impact on a matter of national environmental significance in accordance with EPBC Act Policy Statement 1.1. **Conservation Management Plan for the Blue Whale;** **Conservation Management Plan for the Southern Right Whale;** **Approved Conservation Advice for *Megaptera novaeangliae* (humpback whale); and** **Conservation Advice for Sei and fin Whales** Minimising vessel collision has been ranked as a high priority action within the Conservation Management Plans for blue whale, southern right whale, humpback whale, fin whale and sei whale. During the development of mitigation measures for the Otway Basin 3D MC MSS, the National Strategy for Reducing Vessel Strike on Cetaceans and other Marine Megafauna has been taken into account, reducing the potential for risks associated with ship strike to **ALARP** and **Acceptable Levels** with regard to marine mammals. **Recovery Plan for Marine Turtles in Australia (Commonwealth of Australia 2017)** The Recovery Plan for Marine Turtles in Australia outlines that the long-term recovery objective for marine turtles is to '*minimise anthropogenic threats*' and to '*allow for the conservation status of marine turtles to improve so that they can be removed from the EPBC Act threatened species list*'. Although the OA does not represent an area of high importance to marine reptiles (i.e. no marine reptile BIAs have been identified within or near the OA), the National Strategy for Reducing Vessel Strike on Cetaceans and Other Marine Megafauna was taken into account during the development of mitigation measures and mitigation measures specific to marine reptiles will be implemented during the Otway Basin 3D MC MSS (e.g. installation of turtle guards on tail buoys). The low speed of the Seismic Vessel and installation of turtle guards on each tail buoy is considered to further reduce the potential for risks associated with vessel disturbance to **ALARP** and **Acceptable Levels** regarding marine turtle populations. **AMP Values, Management Prescriptions and IUCN Reserve Management Principle** The environmental and socio-economic values of the AMPs will not be impacted by the physical presence of the Seismic Vessel and towed equipment. Therefore, the management measures are consistent with the IUCN management prescriptions and permissible use of the AMPs. **Conservation Values and objectives of the South-East Marine Reserves Management Plan** The physical presence of the Seismic Vessel and towed equipment are not expected to impact significantly on the environmental values or sensitivities of the SEMR at a local or regional level.

<table>
<tr><th>Criteria for Acceptance</th><th>Acceptability Summary</th></tr>
<tr><td>Social Acceptance – Relevant persons expectations</td><td>Some relevant persons have noted concerns regarding the potential for the Otway Basin 3D MC MSS to impact on SBTF fishing operations. Control measures have been proposed to manage seismic acquisition with the industry.

One relevant person advised that as quotas for southern bluefin tuna increase, the long lining sub-fishery of the SBTF (associated with long liners in the ETBF) may expand in the coming years from the east coast to include a greater level of fishing and searching for new fishing grounds off TAS and VIC. The quota fished by the long line sub-fishery occurs after the quota by the purse-seine fishery has been caught or the season ended, therefore, long liners tend to fish between April and December (the opposite of the purse seine sub-fishery). Long liners may also access deeper offshore waters than the purse seine sub-fishery. Given limited previous effort by long liners in this area (<5 vessels effort reported for the ETBF in waters offshore from Portland) the potential extent and magnitude of interactions is difficult to predict until such shifts in the fishery occur. Generally, it is considered that a survey phase could limit the ability of long liners to access new fishing grounds in the area. However, given that a survey phase will occupy a discrete area and SBT are highly mobile throughout this region, alternative areas will be accessible outside of the survey phase.

Fishers in the TAS giant crab and rock lobster fisheries raised concerns about impacts to their fisheries. The exclusion of acquisition within water depths less than 1,000 m adjacent to the TAS fisheries was requested. Noting that the TAS giant crab stock is currently assessed as depleted, TGS have adopted the requested exclusion.

Rock lobster fishers acknowledged that that the survey is mostly located offshore in deep waters that avoid most rock lobster fishing effort, but on behalf of its members, noted concerns regarding the effects of seismic on the fisheries. They also explained that some deep-water fishing effort occurs occasionally for white lobster and requested that the survey be modified to avoid these areas. Although no such exclusion has been adopted by TGS for rock lobster, the AA already avoids depths and most areas where any fishing effort has previously occurred. The exclusion zone defined for TAS giant crab also has some indirect benefit in this respect for rock lobster. No significant impacts to rock lobster fishing activities are expected.

All concerns raised by relevant persons were considered as part of the EP process and responses were provided to all submissions with further information or feedback as necessary. Results of the impact assessments have been summarised and provided to all relevant persons, when requested. Engagement with all relevant persons will continue for the duration of the EP. All submissions and associated response are provided in Appendix K. Detailed literature reviews were included in the development of the EP and an extensive set of control measures to reduce the overall impacts from the Otway Basin 3D MC MSS on the marine environment and those relevant persons that use the marine environment for their economic wellbeing, to ALARP and an Acceptable Level</td></tr>
<tr><td>External Context – Commonwealth and State Legislative Criteria</td><td>The control measures for reducing the risk associated with the physical presence of the Seismic Vessel and towed equipment throughout the duration of the Otway Basin 3D MC MSS are consistent with the following relevant standards/documents:
International Maritime Organisation (IMO) conventions including STCW and SOLAS;
Relevant ship safety requirements under the Navigation Act 2012:
COLREGS;
Marine Order 21: (Safety of navigation and emergency procedures), 2012;
Marine Order 28: (Operations standards and procedures), 2012;
Marine Order 30: (Prevention of collisions), 2009; and
Marine Order 58: (Safe management of vessels), 2020
Offshore Petroleum and Greenhouse Gas Storage Act 2006 and associated (Environment) Regulations;
Watch-keeping will occur in accordance with the standards set by the ‘International Convention on Standards of Training, Certification and Watchkeeping for Seafarers’; and
Support vessels will adhere to the EPBC Regulations 2000 with regard to interacting with cetaceans.</td></tr>
<tr><td>Industry Best Practice</td><td>Implemented control measures are based on Industry Best Practice including:
The IAGC Environmental Manual for Worldwide Geophysical Operations. Geophysical vessels must exercise care to reduce risk to aquatic life, including marine fauna and other marine users and, where possible minimise interruption to operations and equipment of other marine users; and
The APPEA Code of Environmental Practice Details within this document relate mainly to offshore operations such as offshore exploration and/or drilling and production facilities where disturbance to marine fauna and other marine users should be reduced to ALARP and Acceptable Levels. It emphasises the importance of maintaining public health and safety during all phases of operations.</td></tr>
<tr><td>ALARP</td><td>The total elimination of survey vessels and towed equipment from the project cannot be achieved due to the offshore location of the OA for the Otway Basin 3D MC MSS, lack of commercially available and proven alternative acquisition methods, and health and safety requirements for a MSS. Following the implementation of the control measures, the potential impacts to the marine environment and other marine users arising from the physical presence of the Seismic Vessel and towed equipment will be short-term and restricted in extent to within the immediate vicinity of the vessels and equipment.

Based on the discussions within the EP, including the potential impacts on the environment and the associated control measures to be implemented, the residual risk of impacts arising from the physical presence of the Seismic Vessel and towed equipment throughout the Seismic Survey is considered to be Negligible to Low. It is envisaged that the control measures, especially the temporal and spatial controls will avoid displacement to the sensitive stages of PBW and SRW, as will the adaptive management measures in the BIA. Compensation to commercial fishers through the development of the Commercial Fisheries Compensation Protocol will ensure that commercial fishing licence holders do not experience increased cost encumbrance or loss of income.

With the control measures in place, it is considered that the Otway Basin 3D MC MSS will be acquired so that the environmental impacts and risk on the marine environment and associated receptors within and surrounding the OA are reduced to ALARP.

Therefore, residual risk from the physical presence of the Seismic Vessel and towed equipment associated with the Seismic Survey is considered to be at an Acceptable Level.</td></tr>
</table>

Table 59 Demonstration of Specific Impact and Risk Acceptability for Physical Presence of the Seismic Vessel and Towed Equipment

Receptor Category	Relevant External Context	Defined Acceptable Level	Comparison with Predicted Levels of Impact	Acceptable
Commercial Fisheries	The peak industry body representative for commercial fishing, raised concerns regarding the potential effects of the Seismic Survey on commercial catch level and displacement from fishing grounds. Commercial fisheries data and publications used to inform the impact assessment include: • ABARES Fishery Status Reports 2021 (Patterson *et al*., 2021); • Commercial fishing catch and effort data for the recent five-year period 2016 – 2020 was obtained from the ABARES, VFA, DNRET and PIRSA which allowed spatial and temporal patterns in fisheries catch and effort distribution to be assessed; and • TGS commissioned the SETFIA to compile an additional review of the level of catch made by Commonwealth and State-managed fisheries within the OA, the proportion of each fisheries' total allowable catch and the annual average catch value that it represents (based upon data from the ten years prior to 2021).	Seismic activities are undertaken in a manner such that: • No interference with other marine users occurs to an extent greater than is necessary for the exercise of right conferred by the titles granted to carry out exploration activities. • There is no change to the sustainability status of the fishery; the Otway Basin 3D MC MSS is undertaken in a manner that does not result in serious, irreversible or long-term impacts to key indicator commercial fish populations and to the extent that sufficient spawning fish biomass and recruitment of the stocks may be maintained such that stocks continue to be assessed by DPIRD as sustainable. • There is no increased costs or loss of income for commercial fishing license holders.	• The predicted level of interference to commercial fisheries is no greater than is necessary to exercise of right conferred by the titles granted to carry out exploration activities; • TGS will be requesting all marine traffic remain 10 km away from the Seismic Vessel and the towed streamers, this will essentially create a moving temporary exclusion zone around the Seismic Vessel. • Displacement to fisheries as a result of the physical presence of the Seismic Vessel and towed equipment are likely to be localised and short-term. • The physical presence of the Seismic Vessel and towed equipment are not predicted to impact key indicator commercial fish populations, thereby having negligible effect on the overall sustainability status of the fishery. • A Giant Crab Acoustic Exclusion area will be implemented during the Otway Basin 3D MC MSS in water depths shallower than 1,000 m on the south-eastern boundary, within which there will be no activation of the acoustic source. This will protect giant crabs fished within the TAS giant crab fishery, and will also by default offer protection to rock lobster habitat. • A Commercial Fishing Compensation Protocol will be implemented to formally manage claims by commercial fishers for loss of catch, displacement and lost or damaged fishing gear as a consequence of the Otway Basin 3D MC MSS.	Yes

Acceptability Statement
Impacts and risks classified as 'Type B' or above are considered acceptable if the requirements in **Table 51** can be demonstrated and it can be determined that the predicted levels of impact and/or residual risk are at or below pre-defined Acceptable Levels for that impact or risk, including those described in **Table 52.** Based on the above evaluation, the potential impacts from the physical presence of the Seismic Vessel and towed equipment meets the requirements of the risk acceptability criteria. The control measures that will be implemented throughout the Otway Basin 3D MC MSS have been developed in accordance with these criteria and are considered appropriate to manage the impacts of the physical presence of the Seismic Vessel and towed equipment on all receptors, including the associated disruption and interference with other marine users to an **Acceptable Level.**

7.1.7 Environmental Performance

Table 60 Environmental Performance Outcomes, Standards and Measurement Criteria for Physical Presence of the Seismic Vessel and Towed Equipment

Number	Environmental Performance Outcome	Environmental Performance Standard(s)
EPO 1	Seismic acquisition is undertaken in a manner such that it does not interfere with other marine users to a greater extent than is necessary for the exercise of right conferred by the titles granted to carry out exploration activities.	**EPS 1** to **EPS 3**, **EPS 10** to **EPS 11**, **EPS 19** to **EPS 27**, **EPS 43**, and **EPS 46** to **EPS 50**
EPO 2	Seismic acquisition is undertaken in a manner that prevents any increased cost encumbrance or loss of income to commercial fishing license holders.	**EPS 1** to **EPS 2**, **EPS 19** to **EPS 39**, **EPS 43**, and **EPS 46** to **EPS 52**
EPO 3	Seismic acquisition is undertaken in a manner that limits impacts due to collision or entanglement with vessels or in-water seismic equipment to individual listed threatened, listed migratory or listed marine fauna protected under the EPBC Act to minor, short-term effects and ensures biologically important behaviours can continue.	**EPS 1** to **EPS 2**, **EPS 12** to **EPS 18**, **EPS 40** to **EPS 42**, and **EPS 44** to **EPS 49**.

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
The Otway Basin 3D MC MSS will be undertaken in accordance with the approved EP.	**EPS 1**: The Otway Basin 3D MC MSS may only commence following acceptance of the EP by NOPSEMA.	Pre-mobilisation audit and inspection are completed prior to operations and confirm an accepted EP has been obtained. Audit records verify compliance with the requirements of the EP.	TGS Vessel Operations Manager (**TGS VOM**) Onshore Environmental Advisor (**EA**)
	EPS 2: The Otway Basin 3D MC MSS will be undertaken in accordance with the accepted EP.	Bridge logs verify compliance with the requirements of the EP. Audit records verify compliance with the requirements of the EP.	TGS VOM Seismic Contractor Vessel Operations Manager (**VOC**) EA Vessel Master Survey Environmental Advisor (**SEA**)
All survey vessels will adhere to the requirements of the national and international legislation, including the International Regulations for Preventing Collisions at Sea 1972 (COLREGS) and Chapter 5 of SOLAS as implemented in Commonwealth Waters through the *Navigation Act 2012* and associated Marine Orders 21, 28, 30, 58 and the STCW Convention. The requirements give effect, but are not limited to, the following: • Appropriate use of lighting, navigation and radio communication at sea; and • 24-hour bridge and radar watch by qualified watch-keepers to monitor for other marine users.	**EPS 3**: At all times the Vessel Masters comply with the requirements of national and international legislation and conventions including (but not limited to) the Navigation Act 2012 (specifically Marine Order Part 21, 27, 30, 58) COLREGS, Chapter IV (Radio communications) and Chapter V (Safety of Navigation) of SOLAS (International Convention on the Safety of Life at Sea 1974) and the STCW Convention.	Vessel Crew Training and Competency records demonstrate that all relevant marine crew are competent to STCW95/Elements of Shipboard Safety Standards. Pre-mobilisation audit and inspection are completed prior to operations and identify no records of survey vessels failing to comply with appropriate navigation and communication requirements under the Navigation Act 2012, associated Orders or conventions. Bridge logs verify this during the Otway Basin 3D MC MSS.	Vessel Master Party Chief SEA
	EPS 4: Lighting and communications equipment onboard all vessels to adhere with COLREGS, the *Navigation Act 2012* and with AMSA Marine Orders Part 30: Prevention of collisions, Part 21: Safety and emergency arrangements and Part 27 (safety of navigation and radio equipment).	Pre-mobilisation audit and inspection are completed prior to operations and identify no records of survey vessels failing to comply. Bridge logs verify this during the Otway Basin 3D MC MSS.	Vessel Master Party Chief

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
	EPS 5: The Seismic Vessel displays day shapes and lights (during hours of darkness/poor visibility) to indicate that the vessel is towing equipment resulting in the Seismic Vessel being restricted in its ability to manoeuvre.	Pre-mobilisation audit and inspection are completed prior to operations and confirm that the relevant equipment is onboard, tested and operational. Bridge logs verify this during the Otway Basin 3D MC MSS.	Vessel Master Party Chief
	EPS 6: The survey vessels are equipped with Radar and AIS systems which will be operating and monitored at all times for both transmitting and receiving vessel positions in the surrounding vicinity.	Pre-mobilisation audit and inspection are completed prior to vessel leaving port and confirm Radar and AIS are present and operational. Bridge logs confirm Radar and AIS are used during the Otway Basin 3D MC MSS.	Vessel Master Party Chief
	EPS 7: The Seismic Vessel will have ARPA onboard for the detection of other vessels. The ARPA system can track other vessels speed and heading and can monitor for the potential of any collisions so the vessels can be contacted prior to any situation occurring.	Pre-mobilisation audit and inspection are completed prior to vessel leaving port and confirm ARPA are present and operational. Bridge Logs confirm ARPA is used during the Otway Basin 3D MC MSS.	Vessel Master Party Chief
	EPS 8: The survey vessels will have the appropriate communication equipment onboard and will be contactable and also able to communicate with other vessels by radio at all times (i.e. VHF and SSB radio).	Bridge logs confirm VHF and SSB radio communications are always available.	Vessel Master Party Chief
	EPS 9: Qualified crew maintain 24/7 watch-keeping during the survey in compliance with the STCW Convention. Watch keeping duties includes monitoring of vessel position (radar and plotter) and water depth at all times during seismic acquisition.	Bridge logs verify watch has been undertaken during the Otway Basin 3D MC MSS.	Vessel Master Party Chief
	EPS 10: Watch keepers are qualified in accordance with STCW95 (or equivalent).	Pre-qualification process includes requirement for Contractor to review/provide qualifications/training of crew members. Induction records outline qualifications/training of all crew members.	VOC Vessel Master
Adherence to the prohibition of entry into established Petroleum Safety Zones surrounding petroleum wells, structures, or equipment.	**EPS 11**: The Seismic Vessel will not enter within any established PSZ. There are no PSZ's within the OA; however, if for any reason the survey vessels did have to enter a PSZ, this would only be by prior arrangement with the installation master and all correct permits are obtained.	Bridge logs records demonstrate compliance.	Vessel Master
Vessel masters' of the support vessel/s will comply, when safe to do so, with the relevant requirements of EPBC Regulations 2000 Part 8, Division 8.1, including: • Taking action to avoid approaching or drifting closer than 50 m to an adult dolphin or 100 m to an adult whale; • Taking action to avoid approaching or drifting closer than 150 m to a dolphin calf or 300 m to a whale calf; • Making all efforts not to let a calf enter the caution zone; and • Not exceeding a speed of six knots within the caution zone of a cetacean (300 m).	**EPS 12**: The Support Vessel/Chase Vessel will not intentionally approach or allow their vessel to drift closer than 100 m to any adult whale.	Bridge logs records demonstrate compliance. MFO daily and weekly logs verify compliance	Vessel Master MFOs
	EPS 13: The Support Vessel/Chase Vessel Masters will not intentionally approach or allow their vessel to drift closer than 50 m from any dolphin.	Bridge logs records demonstrate compliance. MFO daily and weekly logs verify compliance	Vessel Master MFOs
	EPS 14: The Support Vessel/Chase Vessel will not intentionally approach or allow their vessel to drift closer than 300 m to any whale calf.	Bridge logs records demonstrate compliance. MFO daily and weekly logs verify compliance	Vessel Master MFOs
	EPS 15: If a cetacean approaches closer than the 100 m, the Vessel Master will either disengage gears or allow the whale to approach or reduce speed to less than 6 knots and steer a course away from the cetacean.	Bridge logs records demonstrate compliance. MFO daily and weekly logs verify compliance	Vessel Master MFOs
	EPS 16: If a dolphin approaches closer than the 50 m, the Vessel Master must not change course or speed of the vessel suddenly.	Bridge logs records demonstrate compliance. MFO daily and weekly logs verify compliance	Vessel Master MFOs
	EPS 17: The vessel master will make all efforts not to let a calf enter the caution zone (either whale or dolphin). However, if it occurs, the Vessel Master will immediately stop the vessel, turn off engines, or disengage gears, or withdraw the vessel from the caution zone at a constant speed of less than 6 knots.	Bridge logs records demonstrate compliance. MFO daily and weekly logs verify compliance	Vessel Master MFOs

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
Any vessel strike incident to marine mammals will be reported as soon as practicable via the National Vessel Strike Database within 72 hours of the incident.	**EPS 18:** Any vessel strike incident to marine mammals will be reported via the National Vessel Strike Database as soon as practicable yet no later than 72 hours following the incident.	MFO daily and weekly logs verify any vessel strike incident has been reported via the National Vessel Strike Database	MFOs SEA Client Site Representative (**CSR**)
A communications protocol will be in place between the survey vessels and other relevant persons (e.g. commercial fishers known to utilise the OA, oil and gas operators), to actively manage concurrent activities.	**EPS 19**: Pre-survey consultation with relevant persons, confirming the Otway Basin 3D MC MSS will proceed, no less than four weeks before operations commence.	Documentation of consultation and consultation log demonstrate compliance.	TGS VOM EA
	EPS 20: Onshore personnel (EA) will communicate any updates determined through the continuing consultation process to the Vessel Master, where they have the potential to impact the Otway Basin 3D MC MSS and/or relevant persons.	Documentation of consultation and consultation log demonstrate compliance. Forms part of continuing consultation strategy.	EA Vessel Master
	EPS 21: Relevant persons will be notified following the conclusion of the survey as per the following Post-Activity Notifications: • All relevant persons – relevant time post completion; • AMSA – relevant time post completion; • NOPSEMA – 10 days post completion advising the completion of the Seismic Survey; and • NOPSEMA – As soon as practicable advising that all of the activities and obligations covered under the EP have been completed.	Documentation of consultation and consultation log demonstrate compliance.	TGS VOM EA
	EPS 22: A 48-hour 'look-ahead plan' will be provided to relevant persons (who register for the service) identified throughout the relevant persons consultation process, detailing the survey activities over the next 48 hours. The 48-hour look-ahead plans will be updated and issued every 24 hours and distributed to relevant persons via email.	Documentation of consultation, consultation log and issuing of weekly and 48-hour look-ahead plans demonstrate compliance. Forms part of continuing consultation strategy.	TGS VOM EA CSR Vessel Master
Notification to AHO for the publication of a Notice to Mariners of survey presence and towed array, no less than four weeks before operations commence.	**EPS 23**: A Notice to Mariners will be published and distributed by the AHO under the Navigation Act 2012, informing other marine users of the Otway Basin 3D MC MSS, no less than four weeks before operations commence.	Record of Notice to Mariners.	TGS VOM EA
	EPS 24: Should any changes occur the survey acquisition plan throughout the duration of the Otway Basin 3D MC MSS, all Notice to Mariners will be updated as soon as reasonably practicable.	An updated Notice to Mariners will be issued.	TGS VOM EA CSR Vessel Master
Notification to the JRCC for the promulgation of navigational warnings (i.e AUSCOAST warnings).	**EPS 25**: The JRCC will be contacted 24 – 48 hours prior to the commencement of survey operations for issuing of radio navigation warnings.	Record of notification to JRCC.	TGS VOM EA
At least one Support Vessel will accompany the Seismic Vessel when in operation and when safe to do so (e.g., outside of inclement weather periods), to manage interactions with other marine users.	**EPS 26**: The support vessel/s will manage vessel interactions through travelling between and maintaining communications with any third-party vessels in the OA.	Bridge logs verify support vessels have successfully communicated with all third-party vessels encountered in the OA.	Vessel Master
	EPS 27: In case of emergency, at least one support vessel will be capable of taking the Seismic Vessel under tow with all equipment deployed (to keep the vessel and in-water equipment under control and in forward motion).	Pre-qualification process includes assessment of support vessels capacity to take the Seismic Vessel under tow. Contractors QHSE Plan confirms how this will be achieved.	TGS VOM VOC Vessel Master
Compensation to fishers and vessel crews (i.e., the claimant) is demonstrated to have occurred for the following circumstances:	**EPS 28**: A Commercial Fisheries Compensation Protocol is in place for the Otway Basin 3D MC MSS.	Documentation of consultation demonstrates Fisheries Compensation Protocol for the Otway Basin 3D MC MSS is in place for the Otway Basin 3D MC MSS.	TGS VOM

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
• Interaction resulting in loss or damage to fishing equipment; • A temporary loss of fish landed catch due to damaged or lost fishing equipment; • Where displacement from fishing grounds results in additional costs incurred due to relocating; or • A temporary reduction in fish landed catch due to the effects of acoustic emissions or displacement from fishing grounds. Claims received from fishers in any circumstances other than those outlined above will not be assessed. Claims will be considered provided the interaction/displacement/loss of catch took place in the Adjustment Area (plus any additional area of avoidance requested around the survey vessels and towed equipment.) where the Otway Basin 3D MC MSS took place, and within the project active time frame only.	**EPS 29**: Pre-survey consultation with commercial fishers known to utilise the OA, notifying them in writing of the Commercial Fisheries Compensation Protocol in place for the Otway Basin 3D MC MSS, no less than 28 days before operations commence. Notification will be via SETFIA, TSIC, SIV, or AFMA (as relevant to each fishery) and will be provided in the form of a map, showing the OA and associated Adjustment Area, plus digital files in formats such as shapefiles and a copy of the Protocol in full.	Documentation of consultation demonstrates the Commercial Fisheries Compensation Protocol is in place for the Otway Basin 3D MC MSS and was provided to commercial fishers known to utilise the OA no less than 28 days before operations commence. Information provided is demonstrated to include a copy of the Protocol in full, a map showing the OA and Adjustment Area, plus digital files in formats such as shapefiles.	TGS VOM
	EPS 30: Eligible Commercial Fishes have been provided application forms and contact point relevant to commercial fishers relating to lodging a claim or notification regarding loss of catch, displacement, or fishing gear loss of damage.	Documentation of consultation demonstrates Attachment A of the Commercial Fisheries Compensation Protocol was attached to the pre-survey consultation with commercial fishers known to utilise the OA, and that contact point has been provided to commercial fishers.	TGS VOM
	EPS 31: Subject to a claim being lodged, a suitably experienced/qualified independent person/organisation will be engaged as the assessor of the claim, in consultation with the claimant. Suitably experienced and qualified is defined as a person or organisation with proven demonstrated experience in data analysis and data auditing processes and procedures within the industry.	Documentation of consultation with claimant around engagement of independent assessor, appropriate experience/qualifications of independent assessor, and agreements in place between TGS and independent assessor to engage their services for assessing the claim.	TGS VOM
	EPS 32: TGS will provide the assessor with a letter of instruction/project brief, which is to also be provided to the claimant as part of the assessment report.	Documentation of communications with assessor and claimant including provision of letter of instruction/project brief.	TGS VOM
	EPS 33: All compensation claims made by commercial fishing license holders or vessel crews for equipment damage/loss, displacement and loss of catch will be assessed for merit in accordance with the processes outlined in the Commercial Fisheries Compensation, within 30 days of receiving the claim.	Records demonstrate that claims made by commercial fishery license holders and vessel crew were assessed in accordance with the processes outlined in the Commercial Fisheries Compensation Protocol.	TGS VOM
	EPS 34: Where a commercial fishing licence holder has been involved in an interaction leading to loss or damage to the licence holder's equipment or displacement from usual fishing grounds, all interactions between the commercial fishing licence holder and the survey vessels will be recorded by the MSS operator. Details to be recorded should include, but not be limited to the time, date and location coordinates of where the gear interaction occurred or the fishing was aborted and where it recommended, the name of the vessel, the licence holder number on the fishing gear, and any details of communications between the commercial fishing licence holder and the vessel/s.	Records demonstrate documentation of interactions with commercial fishing licence holder leading to loss or damage of the licence holder's equipment or displacement from usual fishing grounds.	Vessel Master
	EPS 35: Where possible and safe to do so, the Vessel Master shall make attempts to recover any fishing equipment. Photos will be provided to TGS by the Vessel Master.	Records demonstrate attempts to retrieved fishing equipment and photos of retrieved equipment.	Vessel Master.

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
	EPS 36: The independent assessor is to provide TGS with an assessment report which is to include the following information: - A copy of the letter of instruction/project brief; - Confirmation (or otherwise) that the information provided in the claim is sufficient to conduct a meaningful assessment; - A summary of the claim details (survey, applicant, vessel, month/s); - For a loss of catch claim, monthly CPUE assessments as outlined in the Commercial Fisheries Compensation Protocol, including an estimation of any loss of catch and its market price; and - Any other information, comments, or views relevant to the assessment that the assessor may wish to include. Upon receiving and considering the assessment report, TGS will provide a copy of the report to the claimant and offer to meet with the claimant to discuss/address the claim.	Records demonstrate receipt of assessment report and consultation with claimant.	TGS VOM
	EPS 37: All claimants will be notified of the outcome of the claim (or request clarification/additional information from the claimant) as soon as practicable and within 30 days after receiving the application, in accordance with the Commercial Fisheries Compensation Protocol.	Records demonstrate claimants were notified of the outcome of the claim or request for clarification/additional information, within 30 days of receiving the claim, in accordance with the Commercial Fisheries Compensation Protocol.	TGS VOM
	EPS 38: All claimants considered to have a claim of merit will receive compensation, in accordance with the Commercial Fisheries Compensation Protocol, within 60 days of the claim determination. Claimants will be contacted via the email addressed provided within the claim application, unless requested otherwise. Compensation value paid will calculated based on the measures provided in the Commercial Fisheries Compensation Protocol.	Records demonstrate all claimants considered to have a claim of merit received compensation in accordance with the Commercial Fisheries Compensation Protocol, within 60 days of the claim determination.	TGS VOM
	EPS 39: In the event that a claimant disagrees with a claim assessment outcome, and an agreement cannot be reached between TGS and the claimant, the claimant may, within 30 days, opt to request that a suitably experienced/qualified independent third-party is engaged to review and determine the outcome of the claim. The appointment of the independent third party will be agreed mutually between TGS and the claimant. The dispute will be resolved within 60 days of dispute received by TGS, with the costs of engaging the independent third-party assessor covered by TGS.	Records demonstrate that a claimant's dispute has been assessed by a suitable experience/qualified independent third-party, where requested, and that costs of engaging the independent third-party assessor have been covered by TGS. Records document outcome of the independent third-party assessor's assessment and that the dispute has been resolved within 60 days of receipt of the dispute.	TGS VOM
Development and implementation of Marine Fauna Mitigation Plan. Where possible and safe to do so, marine fauna entangled within in-water equipment will be extricated and returned to sea following the procedures provided within the Marine Fauna Mitigation Plan.	**EPS 40:** One of the roles of the MFOs onboard the Seismic Vessel is to develop a Marine Fauna Mitigation Plan, to be submitted to TGS prior to the pre-mobilisation survey and audit commencing. This plan will demonstrate the following, at a minimum: • MFOs are trained, dedicated and experienced; • Responsibilities and authorities of MFOs to ensure the plan is communicated and available to those roles that are required to implement the controls; • Communications protocols for relaying marine fauna observations to the Seismic Operator, Vessel Master and vessel crew as required. • Survey Plan – describes the proposed activity including location and timing, acoustic source and streamer configuration, equipment (vessels) and key geographic locations such as BIAs and nominated exclusion zones. • Implementation Plan – details how the marine fauna mitigation controls within the EP will be implemented; • Handling procedures for the retrieval of marine fauna entangled in towed equipment or seabirds on the vessels' deck.	Pre-mobilisation audit and inspection confirms the Marine Fauna Management Plan has been developed. Induction records outline the content of inductions and personnel present. MFOs daily and weekly logs and Bridge logs confirm the Marine Fauna Mitigation Plan is being implemented.	SEA CSR MFOs RA

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
	EPS 41: When safe to do so, efforts will be made to extricate and return to sea, any marine fauna entangled within in-water equipment, as per the handling procedures outlined within the Marine Fauna Mitigation Plan.	MFO daily and weekly logs verify the processes followed in the event of marine fauna entanglements.	MFOs SEA CSR
Vessel crew will complete an environmental induction covering the requirements for vessel interactions with marine fauna.	**EPS 42:** Vessel crew will complete an environmental induction covering the requirements for vessel interactions with marine fauna prior to the commencement of activities associated with the Otway Basin 3D MC MSS.	Induction records outline content of environmental induction and attendees.	EA Party Chief SEA Vessel Master
Streamers will be marked with tail buoys.	**EPS 43**: The tail buoy on each streamer is appropriately marked to enable other marine users to determine the extent of the survey and associated array of towed equipment. Each tail buoy includes a radar reflector, lights and an AIS transponder to identify the end of each streamer to other vessels, especially those capable of receiving AIS data.	Pre-mobilisation audit and inspection are completed prior to vessel leaving port and confirm appropriate tail buoys are fitted to each streamer.	Vessel Master Party Chief SEA
Turtle guards will be installed on streamer tail buoys or tail buoys will be of a design that does not represent an entrapment risk to marine turtles.	**EPS 44:** Each streamer tail buoy will be fitted with protective 'turtle guards' that is appropriate for excluding turtles from entering gaps in the subsurface structure of the tail buoys or will be of a design that does not represent an entrapment risk to marine turtles.	Audit/inspection records verify turtle guards are installed or tail buoys are of a design that does not represent an entrapment risk to marine turtles.	Vessel Master Party Chief SEA
Vessels masters' of the support vessel/s will, when safe to do so, take action to avoid approaching or drifting closer than 50 m to a marine turtle or pinniped.	**EPS 45:** Vessels masters' of the support vessel/s will, when safe to do so, take action to avoid approaching or drifting closer than 50 m to a marine turtle or pinniped.	Bridge logs records demonstrate compliance. MFO daily and weekly logs verify compliance	Vessel Master MFOs
The acoustic source will only be deployed and retrieved within the bounds of the OA.	**EPS 46:** The acoustic source will be retrieved and brought onboard the Seismic Vessel when not required and will only be permitted to be in the water when in the bounds of the OA. The acoustic source will not be deployed or, when safe to do so, retrieved when outside the boundaries of the OA.	Bridge logs verify vessel track records and timing of retrieval events. Pre-mobilisation audit and inspection confirms exclusion polygons on survey vessel's navigation system have been developed and are available for use.	Vessel Master Party Chief CSR SEA
	EPS 47: Shape files will be loaded onto the survey vessels' navigation system outlining the boundary extents of the OA and AA.	Exclusion polygons on survey vessel's navigation system.	Vessel Master CSR SEA
Retrieval of any equipment accidentally lost at sea, including streamers, where it is safe and practicable to do so to ensure it does not become a risk to other marine users. Pressure activated streamer recovery devices will be fitted along the streamers.	**EPS 48:** Where practicable and safe to do so, any equipment accidentally lost at sea, including streamers, is retrieved.	Bridge logs verify vessel track records and timing of retrieval events.	Vessel Master Party Chief CSR SEA
	EPS 49: Pressure activated streamer recovery devices will be fitted along the streamers.	Audit/inspection records verify pressure activated streamer recovery devices are fitted along the streamers.	Vessel Master CSR SEA
Access to Seismic Vessel tracking information via Google Earth for fisheries relevant persons who have registered for the service.	**EPS 50:** Access to Seismic Vessel tracking information provided via Google Earth for fisheries relevant persons who have registered for the service.	Consultation log confirms that stakeholders who registered for the service received link for seismic survey vessel tracking information via Google Earth.	EA Vessel Master
Giant Crab Acoustic Exclusion Area within waters 1,000 m or less south of the 2D tie line AA.	**EPS 51:** No seismic acquisition will occur within the boundaries of the Giant Crab Acoustic Exclusion Area.	Bridge logs verify vessel track records and where activation of the acoustic source has occurred.	Vessel Master Party Chief CSR SEA
	EPS 52: Shape files will be loaded onto the survey vessels' navigation system outlining the boundary extents of the OA and AA and the Giant Crab Acoustic Exclusion Area.	Pre-mobilisation audit and inspection confirms exclusion polygons on survey vessel's navigation system have been developed and are available for use.	Vessel Master CSR SEA

7.1.8 Physical Presence Impact and Risk Summary

Based on the assessment above, including the identification of potential impacts on the environment and the associated control measures to be implemented, the residual risk of impacts arising from the physical presence of the survey vessels and towed equipment throughout the Otway Basin 3D MC MSS is considered to range from **Negligible** to **Low**, for the receptors identified.

The suite of control measures determined to be adopted have been developed in accordance with industry best practice and relevant legislation. In accordance with the Risk Ranking Descriptions in **Table 49**, where risk cannot be reduced to '**Low**', additional control measures must be evaluated to determine whether the risk is reduced to **ALARP**.

Additional controls have also been evaluated to determine whether they are effective and practicable to implement in **Table 57**. Where they are determined to effectively reduce the environmental impact and risk, and are practicable to implement, they have been adopted. Consequently, it is considered that the environmental impacts and risk on the identified receptors arising from the physical presence of the Seismic Vessel and towed equipment throughout the duration of the Otway Basin 3D MC MSS, are reduced to **ALARP**.

In accordance with the acceptability requirements prescribed in **Section 6.4,** the suite of control measures, are considered appropriate to manage the impacts arising from the physical presence of the Seismic Vessel and towed equipment on all receptors, specifically commercial fishers, to an **Acceptable Level.**

7.2 Acoustic Disturbance to the Marine Environment

7.2.1 Description of Source of the Impact and Risk

Noise will be generated from two sources during the Otway Basin 3D MC MSS, including the survey vessels, and the active acoustic source. The active acoustic source generates much higher noise levels than the vessels and would dominate overall underwater noise emissions at times when data acquisition is occurring.

7.2.1.1 Vessel Noise

Vessel noise (i.e. from propellers, machinery, and the passage of the hull through water) is the dominant anthropogenic sound in marine waters, adding to the constant ambient noise level in the marine environment. In general, older vessels produce more noise than more modern vessels, and larger vessels produce more noise than smaller vessels (Gordon and Moscrop, 1996). Commercial vessels produce relatively loud and predominantly low frequency sounds, with the exact characteristic's dependant on the type, size, and operational mode of the vessel (**Table 40**). A study undertaken by MacGillivray and Li (2018) recorded vessel noise in Haro Strait and found underwater noise generated by commercial vessels is significantly reduced at slower vessel speeds. For vessel noise, the strongest energy tends to be at frequencies below several hundred hertz, with source levels generally ranging from 180 – 190 dB re 1 µPa (Southall and Hatch, 2008).

Noise emissions from the survey vessels would be similar in level, frequency range, and character to noise from general shipping traffic already in the Otway Basin and is not considered to represent a significant additional environmental impact above the noise from normal shipping activities.

Table 40 Noise Outputs from a range of Commercial Vessels

Source	Source level (dB re 1 µPa at 1 m)	Reference
Container ship (294 m and 298 m length)	184.2 – 186.6 and 188.1	McKenna *et al.*, 2012
Container ship	183.8 – 199.1	MacGillivray and Li, 2018
Vehicle carrier (173 m and 199 m length)	180.0 and 180.8	McKenna *et al.*, 2012
Vehicle carrier	183.6 – 195.2	MacGillivray and Li, 2018
Bulk carrier (167 m and 229 m length)	187.4 and 185.1	McKenna *et al.*, 2012
Bulk carrier	181.9 – 193.9	MacGillivray and Li, 2018
Open hatch cargo ship (190 m and 213 m length)	183.8 and 181.1	McKenna *et al.*, 2012
Chemical products tanker (148 m and 182 m length)	182.4 and 184.9	McKenna *et al.*, 2012
Crude oil tanker (229 m and 243 m length)	181.3 and 182.1	McKenna *et al.*, 2012
Product tanker (180 m and 228 m length)	181.8 and 182.7	McKenna *et al.*, 2012
Tanker	183.6 – 195.2	MacGillivray and Li, 2018
Super tanker (266 m and 337 m length)	187 and 185	Thiele, 1983
Cruise ship	175.5 – 198.3	MacGillivray and Li, 2018
Fishing trawler	158	Malme *et al.*, 1988

7.2.1.2 Underwater Acoustic Modelling

7.2.1.2.1 Introduction

Underwater Acoustic Modelling (**UAM**) was undertaken to predict received noise levels, or the 'footprint' of acoustic emissions generated from the Otway Basin 3D MC MSS. UAM increases the understanding of the acoustic footprint over a given bathymetric environment with unique environmental parameters (i.e. sound speed profile and geology) and incorporates the characteristics of the specific acoustic source for any proposed seismic survey.

The results generated by the UAM process are used to develop appropriate Precaution Zones as required under Policy Statement 2.1 and to enable an assessment of the potential risk to marine fauna of interest from the OA based on comparisons with known injury and behavioural onset thresholds. Potential risks to the ecological character of sensitive marine areas in the vicinity of the OA are also considered.

For the proposed Otway Basin 3D MC MSS, UAM was undertaken by JASCO. The resulting UAM report (Welch *et al*., 2023) provides a comprehensive description of the methodology and results, and is included as **Appendix B**.

In summary, the UAM approach involved three key components:

- Array source modelling – used to predict acoustic signatures and spectra accounting for individual airgun volumes, airgun bubble interactions, and array geometry. This modelling is used to yield accurate source predictions;
- Underwater acoustic propagation modelling – used to estimate sound levels over a large area around the acoustic source, considering source directivity and range-dependent environmental properties likely to be encountered within the OA. Single-impulse (or per-pulse) and accumulated (24 hour) sound exposure levels (**SELs**) were predicted; and
- Animal movement and exposure modelling (**animat modelling**) – this modelling considers the movement of both the acoustic source and species of interest over time. In this case, the animat modelling involved simulations to predict the distance at which foraging pygmy blue whales (*Balaenoptera musculus brevicauda*) and migrating southern right whales (*Eubalaena australis*) are expected to be exposed above specified thresholds.

In the case of the Otway Basin 3D MC MSS, UAM was conducted specifically for the discharge of the 3,480 in^3 source array. If the final source utilised for the Otway Basin 3D MC MSS differs to that modelled by Welch *et al*. (2023), additional modelling will be undertaken to confirm that the far-field horizontal source level specifications are consistent with those assessed in this EP. As described in **Appendix B**, the sound speed profile for the month of September was selected on account of its slightly upward refracting characteristics that represent the worst-case scenario for noise propagation. This promotes the prediction of worst-case environmental impacts and therefore ensures that controls developed to address these impacts are precautionary.

Geoacoustic parameters used for modelling at all sites were derived from sedimentary grain size measurements from the Australian Government's Marine Sediments (**MARS**) database (Heap, 2009). On average, the surficial grain size on the continental slope indicates silty sand is present. For the deeper sites, the substrate is characterised by clayey sand, but as depth increases past ~200 m the sediment becomes lithified (Feary, 2000).

7.2.1.2.2 Modelling Scenarios

For the purpose of the UAM, the OA was divided into three Assessment Areas with a nominal acquisition scenario defined for each. Sixteen single impulse sites were defined across the three Assessment Areas, as well as five standalone sites, including two sites that were selected to be representative of the 2D tie line. The locations of the modelled sites are illustrated in **Figure 75**. Water depths across all sites ranged from 114 to 4,252 m. Since the original modelling was undertaken, the OA has been reduced in size meaning that Area 3 now lies outside the boundary of the OA. However, Area 3 modelling results are still considered to be relevant for sites with similar seismic source orientation and environmental properties (i.e. bathymetry, sound speed profile and geology of the seabed). Both versions of the OA (original and revised) are shown in **Figure 75**. A speed of 4.5 knots and an inter-pulse interval of 12.5 m was assumed. At the time and location of each seismic pulse, the modelled source location with the closest distance was selected for exposure modelling.

The single impulse sites and accumulated SEL scenarios were determined based on a proposed survey line plan, considering proximity to key features and inclusive of depths that support the greatest sound propagation towards the BIAs near the OA. The acquisition period for each scenario excludes turn duration, as the acoustic source will shut down during line turns. The single impulse sites and accumulated SEL scenarios are considered representative of the range of water depths for locations within the OA where the acoustic source will be active and the potential sound propagation characteristics that may arise during survey acquisition. Seafloor sound levels were assessed at nine different representative depths within the OA. Only seafloor sound levels were assessed at the two sites along the 2D tie line, and the depths were chosen to be representative of relevant densities and distributions for seafloor invertebrates.

Additional sound pressure level (**SPL**) receiver locations were chosen at key BIAs to assess possible impacts to PBWs, SRWs and Australian sea lions.

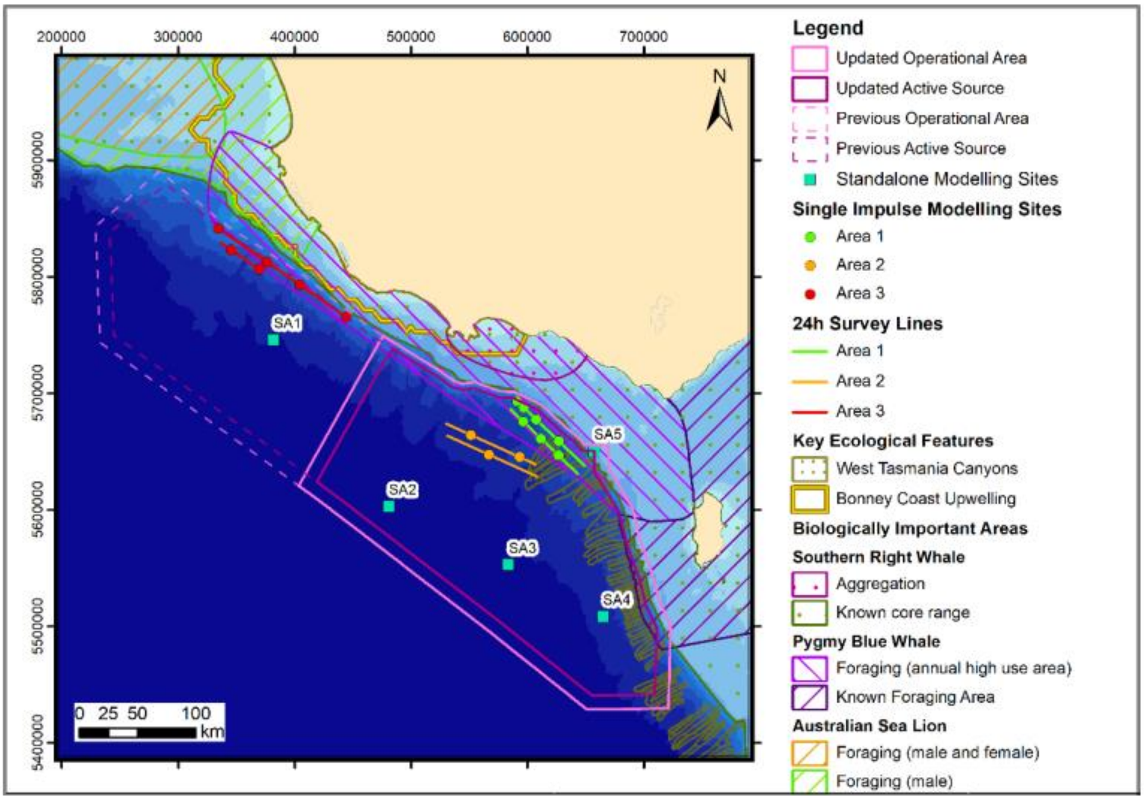

Figure 75 Overview of Modelled Sites and Acquisition Lines

7.2.1.2.3 Noise Effect Criteria

The following discussion is based on, and in some cases an excerpt from, the UAM contained within **Appendix B**, by Welch *et al*. (2023).

The perceived loudness of sound, especially impulsive noise such as from an acoustic source, is not generally proportional to the instantaneous acoustic pressure. Rather, perceived loudness depends on the pulse rise-time and duration, and the frequency content. Several sound level metrics are commonly used to evaluate noise and its effects on marine life. The period of accumulation associated with SEL is defined, referencing either a "per pulse" assessment or over 24 hours (**Appendix B**). The acoustic metrics used reflect the updated ISO standard for acoustic terminology, ISO/DIS 18405:2017 (2017).

Whether acoustic exposure levels might injure or disturb marine mammals is an active research topic. Since 2007, several expert groups have developed SEL-based assessment approaches for evaluating auditory injury, with key works including Southall *et al*. (2007), Finneran and Jenkins (2012), Popper *et al*. (2014), United States National Marine Fisheries Service (NMFS 2018), and Southall *et al*. (2019). The number of studies that have investigated the level of behavioural disturbance to marine fauna by anthropogenic sound has also increased substantially.

For benthic invertebrates, available literature suggests particle motion, rather than sound pressure, is a more important factor for crustacean and bivalve hearing. Particle motion relates to the movement of fluid particles in a sound field. Water depth and acoustic source size are related to the particle motion levels at the seafloor, with larger arrays and shallower water being related to higher particle motion levels, more likely relevant to effects on crustaceans and bivalves. Acoustic particle motion has been reported in terms of acceleration (ms^{-2}) at the seafloor.

The following noise criteria and sound levels for this study were chosen because they include standard thresholds, thresholds suggested by the best available science, and sound levels presented in literature for species with no suggested thresholds:

1. Peak pressure levels (PK; L_{pk}) and frequency-weighted accumulated sound exposure levels (SEL; $L_{E,24h}$) from (Southall *et al*., 2019) for the onset of Permanent Threshold Shift (**PTS**) and Temporary Threshold Shift (**TTS**) in marine mammals;
2. Marine mammal behavioural threshold based on the current US National Oceanic and Atmospheric Administration (NOAA, 2019) criterion for marine mammals of 160 dB re 1 µPa (SPL; L_p) for impulsive sound sources;
3. Sound exposure guidelines for fish, fish eggs and larvae (including plankton) (Popper *et al*., 2014);
4. Peak pressure levels (PK; L_{pk}) and frequency-weighted accumulated sound exposure levels (SEL; $L_{E,24h}$) from Finneran *et al*. (2017) for the onset of PTS and TTS in turtles;
5. Sea turtle behavioural response threshold of 166 dB re 1 µPa (SPL; L_p) (NSF 2011), as applied by the US NMFS, along with a sound level associated with behavioural disturbance 175 dB re 1 µPa (SPL; L_p) (McCauley *et al*.; 2000a; 2000b);
6. Peak-peak pressure levels (PK-PK; $L_{pk\text{-}pk}$) and particle acceleration (ms^{-2}) at the seafloor to help assess effects of noise on crustaceans through comparing to results in Day *et al*. (2016), Day *et al*. (2019), Day *et al*. (2016a), Day *et al*. (2017) and Payne *et al*. (2008);
7. A sound level of 226 dB re 1 µPa (PK; L_{pk}) reported for comparing to Heyward *et al*. (2018) for sponges and corals;

8. An SPL human health assessment threshold of 145 dB re 1 µPa (SPL; L_p) for sound exposure to people swimming and diving derived from Parvin (2005), and considering Ainslie (2008); and
9. A squid/octopus startle (inking) response sound level of 162 dB re 1 µPa2s per-pulse SEL (L_E) (Fewtrell and McCauley 2012).

The modelling methodology considered source directivity and range-dependent environmental properties likely to be encountered in the OA. Estimated underwater acoustic levels are presented as sound pressure levels (SPL, L_p); zero-to-peak pressure levels (PK, L_{pk}); peak-to-peak pressure levels (PK-PK; $L_{pk\text{-}pk}$); and either single-impulse (i.e., per-pulse) or accumulated sound exposure levels (SEL, L_E) as appropriate for different noise effect criteria outlined above. Further details of the relevant noise effect criteria used are presented in **Section 7.2.2.**

7.2.1.2.4 Acoustic Source Levels and Directivity

The source levels and directivity of the acoustic source presented in the UAM report included in **Appendix B** were predicted using JASCO's Airgun Array Source Model (**AASM**). AASM considers array layout including the volume, tow depth and firing pressure of each array component, and interactions between components. The acoustic source was modelled over AASM's full frequency range, up to 25 kHz.

Table 62 presents the peak and per-pulse SEL source levels in the horizontal-plane broadside (perpendicular to the tow direction), end-fire (along the tow direction), and vertical directions for the modelled triple 3,480 in^3 source. The vertical source level that accounts for the "surface ghost" (the out of phase reflected pulse from the water surface) is also presented to make it easier to compare the output of other acoustic source models.

Table 62 Far-field Source Level Specifications for the 3,480 in^3 Source for a 7 metre Tow Depth

Direction	Peak source pressure level ($L_{S,pk}$; dB re 1 µPa m)	Per-pulse source SEL ($L_{S,E}$; dB 1 µPa^{2}m^{2}s)	
		10–2000 Hz	2000–25000 Hz
Broadside	248.9	225.1	185.3
Endfire	247.7	224.9	190.4
Vertical	258.3	231.2	197.6
Vertical (surface affected source level)	258.3	233.8	200.6

Note: Source levels are for a point-like acoustic source with equivalent far-field acoustic output in the specified direction. Sound level metrics are per-pulse and unweighted.

7.2.1.2.5 Single-impulse Sound Fields

Acoustic source and propagation modelling was done at 16 single-impulse sites. The modelling assessed the per-pulse sound fields in terms of maximum-over-depth SPL, SEL, PK, and seafloor PK and PK-PK. These metrics were assessed as they are used for peak thresholds, as inputs into 24-hour SEL scenarios or correspond with the relevant behavioural thresholds.

The following per-pulse results are presented in Section 5.2 of **Appendix B**:

- Maximum and 95% distances to per-pulse SEL and SPL metrics for the water column;
- Threshold for diver human health;
- The SPL sound fields; and
- Maximum distances to maximum-over-depth water column PK thresholds.

Two examples of the SPL sound fields are presented in **Figure 76**. The implications of these results are discussed for the relevant environmental receptors in **Section 7.2.2**.

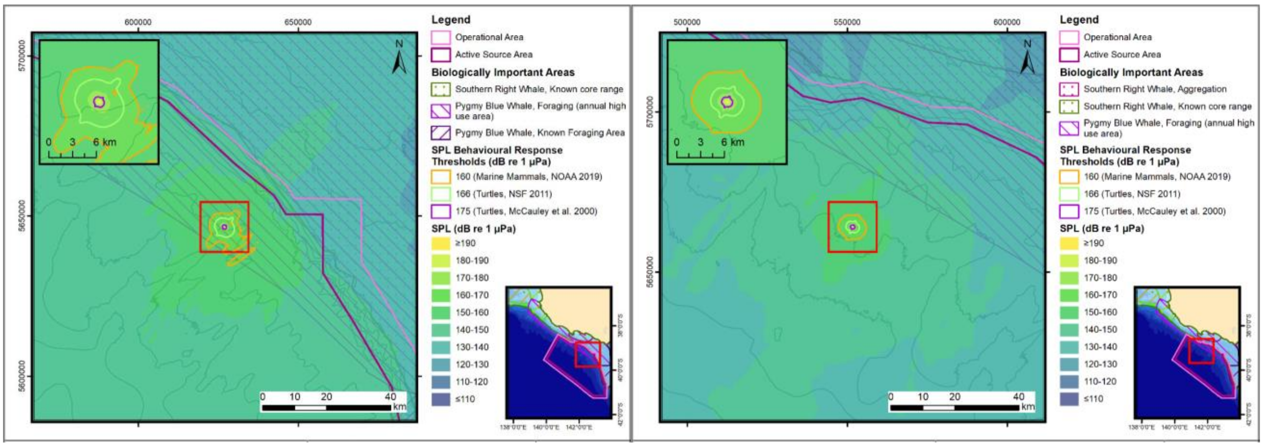

Figure 76 Example Sound Level Contour Maps of Unweighted Maximum-over-depth Water Column SPL Sound Field (Left: Area 1, Site 7; Right: Area 2, Site 2)

Specific modelling was undertaken to assess sound levels at the seafloor; receptor locations at 5 cm and 50 cm above the seafloor interface were assessed as being of relevance to benthic invertebrates, and sponges, corals, and fish respectively. These results are also provided in Section 5.2 of **Appendix B**.

In addition, JASCO modelled particle acceleration for a receiver 5 cm above the seafloor at nine water depths ranging from 114 m to 1,216 m. These were modelled to a maximum distance of 1,000 m from the centre of the acoustic source in the endfire and broadside directions. The results show that the effects are generally greater for the broadside directions than the endfire directions (as shown in **Figure 77** for both the deepest and shallowest sites). The particle acceleration threshold of 37.57 ms^{-2} (derived for scallops by Day *et al*. (2016)) was not predicted to occur at any range for any of the modelled sites.

The maximum predicted received SPL at the edge of each relevant BIA (PBW, SRW and Australian sea lions) are also presented in Table 35 of **Appendix B**.

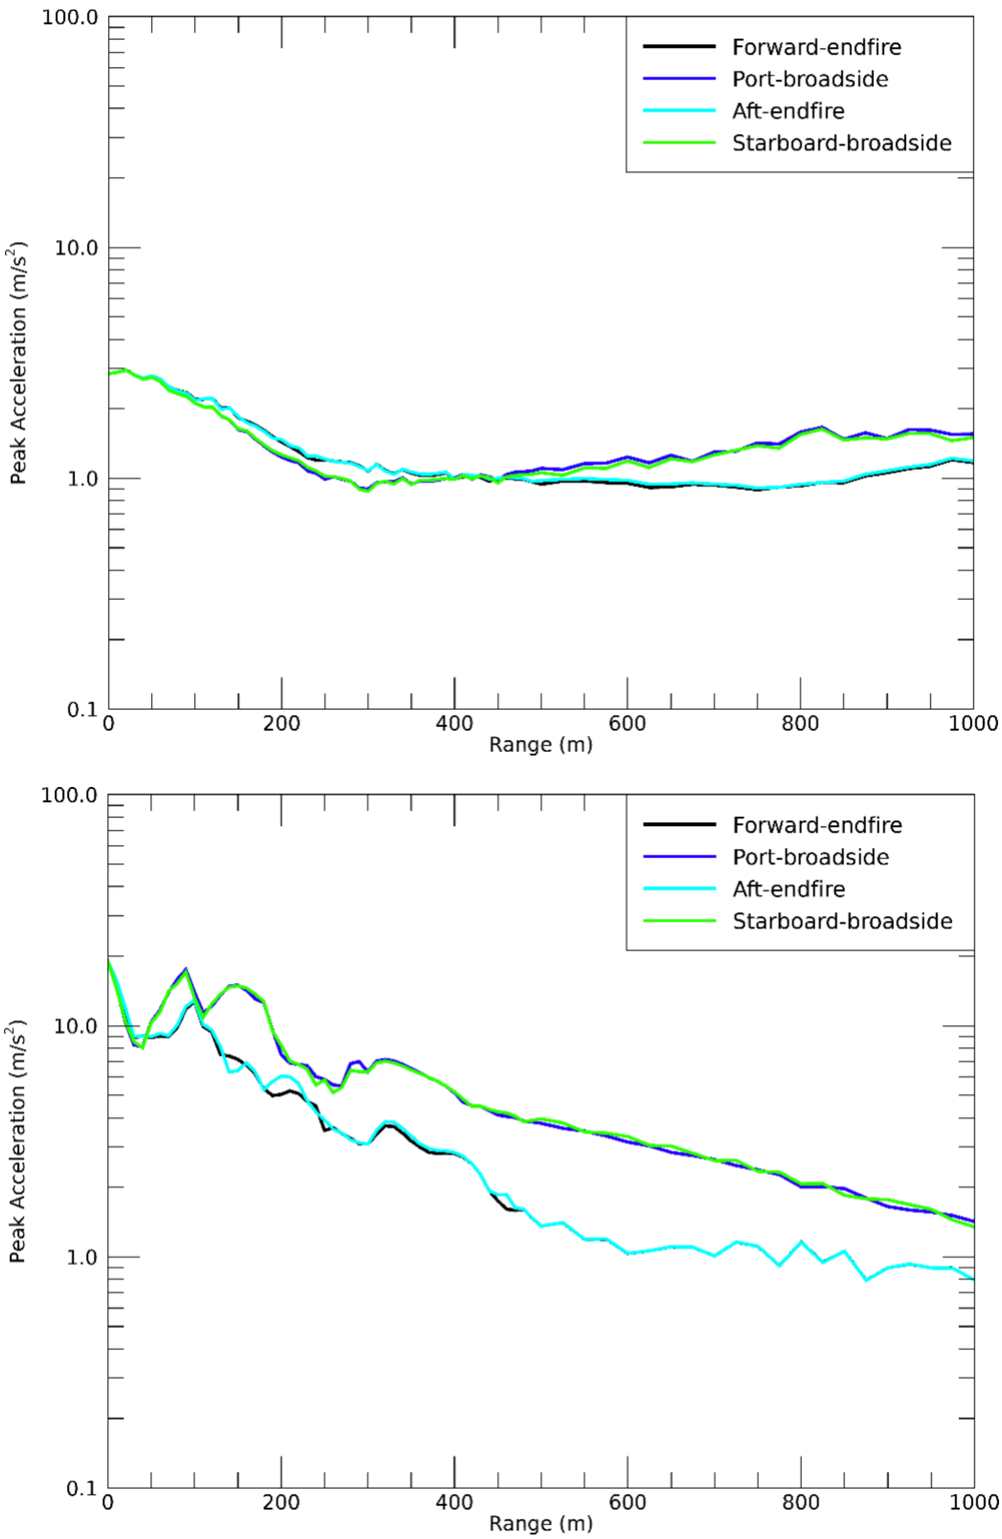

Figure 77 Peak Particle Acceleration at the Seafloor as a Function of Horizontal Range from the Centre of the Acoustic Source along four directions at 1,216 m (top) and 114 m (bottom) Water Depth

7.2.1.2.6 Multiple Source Sound Fields

Sound fields in terms of SEL accumulated over 24-hours of survey within the water column and at the seafloor were determined for the modelled scenarios. Frequency-weighted SEL_{24h} sound fields were used to estimate the maximum horizontal distances (**R_{max}**) to marine mammal and marine turtle PTS and TTS thresholds, and to estimate maximum distance and the area for mortality, injury, and TTS for fish.

The SEL_{24h} sound fields for water column and seafloor are presented as contour maps in Section 5.3 of **Appendix B** and an example of each is presented in **Figure 78**.

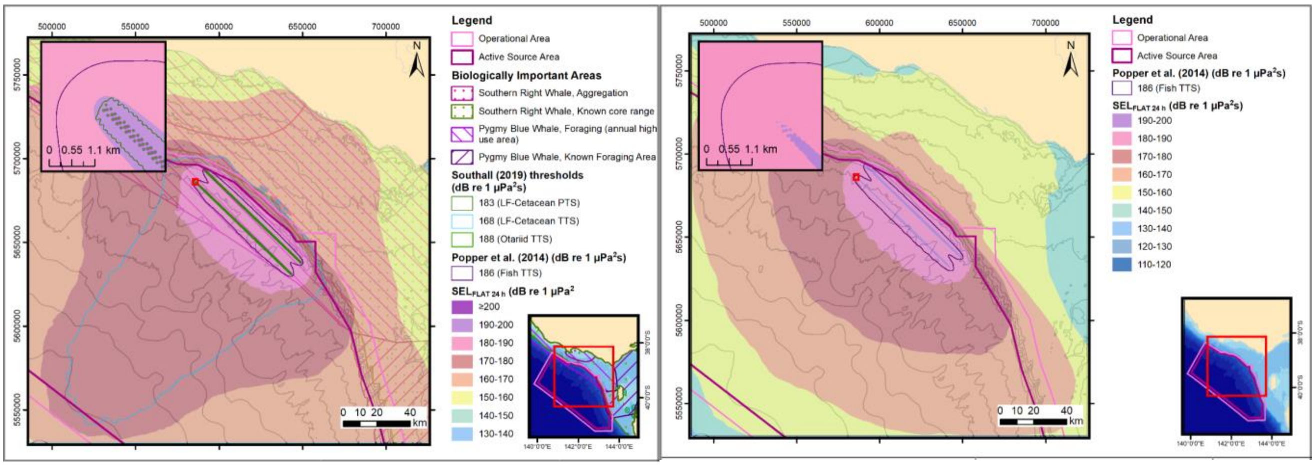

Figure 78 Example Sound Level Contour Maps of Unweighted Maximum-over-depth SEL_{24h} for Area 1: Water Column (left) and Seafloor (right)

7.2.1.2.7 Animal Movement and Exposure Modelling (Animat Modelling)

JASCO's Animal Simulation Model Including Noise Exposure (**JASMINE**) was used to predict the exposure of animats to sound arising from the Otway Basin 3D MC MSS. JASMINE integrates the predicted sound field with biologically meaningful movement rules for each marine mammal species (PBW and SRW in this case) that results in an exposure history for each animat in the model.

Animats are programmed to behave like the marine animals that may be present in an area. The input parameters used for forecasting realistic behaviours (e.g. diving and foraging depth, swim speed, surface times) are determined from marine mammal studies. To evaluate PTS, TTS and behavioural response, exposure results for animats were obtained using the following detailed behavioural information:

- As data on fine-scale foraging behaviour for PBW are not available, data from multi-sensor tags deployed on blue whales off the coast of California were used to inform the feeding behaviours expected in the OA. Data from eight tagged blue whales revealed differences in feeding modes between both shallow and deep feeding and between males and females (Irvine *et al.*, 2019). To account for these differences, female and male pygmy blue whales were modelled separately for the purpose of this EP. Additional data from Goldbogen *et al.* (2011) and Möller *et al.,* (2020) was also used to inform animat behaviour for PBW; and
- For SRWs, separate behavioural profiles were modelled for mother/calf pairs that are expected to spend significantly more time resting at the surface (Cusano *et al.*, 2019; Nielsen *et al.*, 2019) and all other demographics for which migration behaviours were inferred from Double *et al*. (2014), Mackay *et al.* (2020), Baumgartner and Mate (2003), Nousek McGregor (2010), and Dombroski *et al.* (2021).

A depiction of animat movements in a moving sound field is shown in **Figure 79**, with the example animate (red) shown moving with each time step. The acoustic exposure of each animat is determined by where it is in the sound field, and its exposure history is accumulated as the simulation steps through time. For cumulative metrics, an individual animats sound exposure levels are summed over a 24-hour duration to determine its total received energy, and then compared to the relevant threshold criteria.

The sound received by an animat at any given time depends on its location relative to the source. Because the true locations of the animats within the sound fields are unknown, realistic animal movements are simulated using repeated random sampling of various behavioural parameters. Sound exposure distribution estimates were determined by moving large numbers of animats[14] through a modelled time-evolving sound field, computed using specialised sound source and sound propagation models. This approach provides the most realistic prediction of the maximum expected SPL and SEL_{24h} for comparison against the relevant thresholds.

Animat simulations were run for Assessment Area 1 for PBW and SRWs considering four scenarios to predict how exposure levels varied depending on acquisition location relative to the continental shelf. These scenarios and the results generated are discussed in detail in **Section 7.2.2.2.7**.

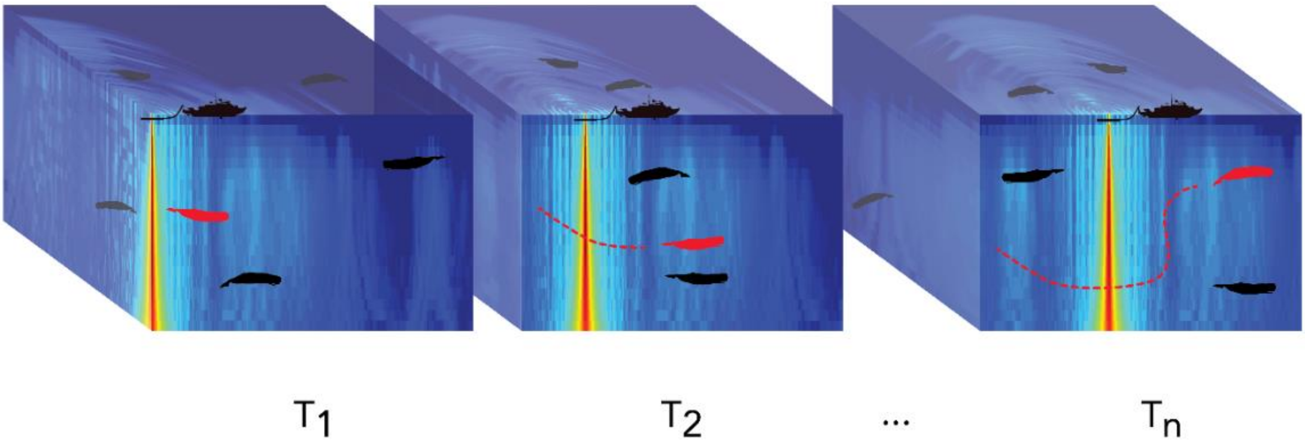

Figure 79 Depiction of Animats in a moving Sound Field

[14] To generate statistically reliable probability density functions, model simulations were run with animat sampling densities of 4 animats/km^2.

7.2.2 Evaluation of Known and Potential Impacts and Risks to Environmental Receptors

Using the information presented in **Section 4** to **Section 5**, the impact and risk assessment has been undertaken for those receptors determined to be relevant to the activity as listed in **Table 63**.

Table 63 Environmental Receptors Assessed

Receptor	Section reference
Plankton	**Section 7.2.2.2**
Benthic Invertebrates	**Section 7.2.2.2.1, Section 7.2.2.3.1**
Fish	**Section 7.2.2.2.3, Section 7.2.2.3.2, Section 7.2.2.4.1**
Cephalopods	**Section 7.2.2.2.5, Section 7.2.2.3.4**
Marine Reptiles	**Section 7.2.2.2.6, Section 7.2.2.3.5**

Biologically Important Areas	**Section 7.2.2.5.2**
Key Ecological Features	**Section 7.2.2.5.3**

7.2.2.1 Noise Effect Criteria

Noise exposure thresholds are indicative noise levels at which there is potential for certain effects (e.g. mortality, temporary hearing impairment, injury, behavioural changes) to occur to marine receptors. When noise exposure thresholds are published, the response of that particular receptor being exposed to that level of noise is generally defined for a single noise exposure or for cumulative exposure to successive events. For the purpose of this EP, threshold criteria for different fauna have been selected to assist in determining and assessing potential physical, physiological, behavioural and, ultimately, ecological impacts. The threshold criteria adopted for this EP are based on current relevant scientific literature, accepted industry and international standards and are considered to be appropriate for this assessment process.

Generally speaking, a high intensity external stimulus such as an acoustic disturbance will elicit a behavioural response in animals; typically, avoidance or a change in behaviour. The duration and intensity of an animal's observed response is impacted by the nature (continuous or pulsed), source (visual, chemical, or auditory) and the intensity of the stimulus, as well as the individual's species, gender, reproductive status, health and age.

Behavioural responses are instinctive survival mechanisms that serve to protect animals from injury. Consequently, animals may suffer temporary or permanent physiological effects in cases when the acoustic disturbance is too high, or the animal is unable to elicit a sufficient behavioural response (e.g. swim away fast enough).

Depending on the exposure level and sensitivity threshold of each species, the effects of acoustic disturbance can include:

- Physiological effects – changes in hearing thresholds – TTS or PTS damage to sensory organs or traumatic injury; (**Section 7.2.2.2**);
- Behavioural effects (and related impacts) – displacement/avoidance, disruption of feeding, breeding, or nursery activities etc. (**Section 7.2.2.3**);
- Perceptual effects (auditory masking) – interference with communication (**Section 7.2.2.4**) and detection of predators/prey; and
- Indirect effects – behavioural changes in prey species that affects other species higher up in the food chain and could lead to ecosystem level effects (discussed throughout **Section 7.2.2** as relevant, in particular see **Section 7.2.2.3.1**, **7.2.2.3.2, 7.2.2.3.3** and **7.2.2.3.7**).

The following subsections go through each of the different marine receptors that are likely to be present in the OA and a risk assessment is undertaken for those species expected to be exposed to the acoustic disturbance arising from the Otway Basin 3D MC MSS. Threshold criteria for behavioural disturbance, TTS, PTS, and other injuries are discussed in the following subsections, alongside the maximum distance from the acoustic source at which these thresholds were reported to occur.

7.2.2.2 Potential Physiological Impacts

Underwater noise, such as that produced during an MSS, has the ability to cause lethal and non-lethal physiological trauma or injury in marine organisms (Gordon *et al*., 2003).

Of particular concern with regard MSSs and marine organisms is the potential for auditory damage from the acoustic release. Tissue damage to sensory organs from MSS acoustic releases have been experimentally studied in captive/captured fish, cephalopods, and invertebrates, while shifts in hearing thresholds have been experimentally observed in some small pinnipeds and small cetaceans and hypothesised based on observed effects in terrestrial animals. To date there is no direct evidence of damage to the ears of marine mammals from MSS acoustic releases (Gordon *et al*., 2003).

The following provides a discussion on the potential physiological effects of MSSs on marine organisms.

7.2.2.2.1 Plankton

The term 'plankton' describes the drifting organisms that inhabit aquatic environments and includes phytoplankton (plants) and zooplankton (animals), as well as fish and invertebrate eggs and larvae, called ichthyoplankton. There is currently no published information regarding the potential for noise-induced effects on phytoplankton and no functional cause-effect relationship has been established; therefore, impacts from acoustic disturbance on phytoplankton is not considered further.

In comparison to fish and mammals, less research has been conducted on the effects of seismic outputs on zooplankton. This is because zooplankton do not have hearing structures although they can detect changes in pressure (Richardson *et al.,* 2017).

Of the few studies of the effects of seismic sound exposure on plankton, some have found that exposure to emitted sound levels from a seismic survey has no significant adverse effects on the abundance or mortality of zooplankton, such as:

- CarbonNet (2018) assessed zooplankton communities in Australia's Gippsland Basin before and after a seismic survey. Ten sites were sampled during the pre-survey period, consisting of six sites occurring within the survey area and four reference sites. During the post-survey period, three sites were sampled near the survey line, as well as three reference sites. Post-survey sampling occurred within three days of acquiring the last survey line. Copepods, cladocerans and salps dominated the pre-survey samples, whereas the dinoflagellate *Noctiluca scintillans* dominated the post-survey samples. There was a high level of variance among samples and no lobster or scallop larvae occurred in any of the samples. Mortality rates were high in both pre- and post-survey samples and the high proportion of dead cladocerans was contributed to their delicate structure being destroyed by the sampling process rather than attributable to any MSS impacts; and
- Sætre and Ona (1996) examined the mortality rates for fish larvae and fry (taken from Booman *et al*., 1996) for five fish species (cod, saithe, herring, turbot, and plaice) to investigate the consequences that seismic-induced mortality may have at the population level. Under a 'worst-case' scenario, the number of larvae killed during a typical seismic survey (>10 days) was 0.45% of the total larvae population. However, when compared with the high natural mortality rates for each species (e.g. cod and herring eggs/larvae have a natural daily mortality of 5 to 15%) the impacts of seismic surveys on these zooplankton at a population level were considered to be negligible.

In studies where seismic impacts have been observed, many have shown them to be limited to within a range of approximately 10 m from an operating seismic array (Richardson *et al*., 2017), with lost individuals quickly being replaced due to rapid generational turnover rates. For example, Kostyuchenko (1973), Booman *et al*., (1996), and Payne *et al.,* (2009) have reported physiological/pathological effects occurring in zooplankton exposed to an acoustic source up to 5 m away, and mortality occurring when exposed to an acoustic source up to 3 m away. Using a 10 m impact range, McCauley (1994) calculated that plankton mortality would be <1% of plankton in the surveyed area assuming total plankton mortality within this range.

In a more recent real-world study, Day *et al.* (2021) examined the potential impacts of an MSS on the larval stages of southern rock lobster to determine whether early development and recruitment of this species might be affected. This study assessed three aspects, the mortality rates following exposure, impairment of the righting reflex, and the development of exposed lobsters through assessment of progression through the moult cycle. The key results from this study on these three aspects are as follows:

- Exposure did not result in any elevated mortality for puerulus or juveniles;
- Righting was significantly impaired for all exposure treatments immediately after exposure compared to their respective controls which indicated that the impact range extended to at least 500 m from the source, which was the maximum range tested in the study; and
- The results provided evidence of a range threshold for recovery, where juvenile lobsters at a nominal distance of 500 m from the source recovered from impairment after the first moult. Increased intermoult duration suggested impacted development and potentially slowed growth, through the proximate cause was not identified.

In contrast to the studies outlined above, McCauley *et al*. (2017) found that after exposure to a single 150 in^3 acoustic source there was a statistically significant lower abundance of zooplankton, with a median 64% decrease one hour after exposure. McCauley *et al*. (2017) observed impacts out to the maximum 1.2 km range sampled, which was more than two orders of magnitude greater than the previously assumed impact range of 10 m. However, this study was compromised by methodological design (small samples sizes, large daily variability in the baseline and experimental data) and the statistical robustness of the data and conclusions (large number of speculative conclusions that appear inconsistent with the data collected over a two-day period).

Richardson *et al*. (2017), through the CSIRO simulated the large-scale impact of a seismic survey on zooplankton in the Northwest Shelf region of Western Australia, based on the mortality rate associated with seismic noise exposure reported by McCauley *et al.* (2017). The mortality rate associated with seismic exposure reported by McCauley *et al*. (2017) was applied alongside other natural/typical variable values. The hypothetical survey area was 80 km by 36 km in water 300 – 800 m deep and the survey was conducted over 35 days. Overall, the model results showed that zooplankton populations were substantially impacted within the seismic survey area out to a distance of 15 km. Predicted impacts were barely discernible within 150 km of the survey area and there was no apparent effect at a regional scale. The simulation showed that, following exposure, there was a rapid recovery of zooplankton populations due to their fast growth rates and the dispersal and mixing of individuals from inside and outside of the impacted region (Richardson *et al*., 2017). The assessment of these results by the IAGC (2017) review was that even if the full effect claimed by McCauley *et al*. (2017) did in fact exist, zooplankton abundance would not be adversely affected due to the extensive movements of water masses carrying zooplankton through survey areas and the rapid reproductive cycle and high reproductive potential characteristics of planktonic organisms. The IAGC (2017) review concluded that the purported findings of McCauley *et al*. (2017) were of no ecological consequence, given the life history parameters of zooplankton.

In addition to Richardson *et al*. (2017), Fields *et al.* (2019) exposed captive zooplankton (copepods) at a variety of distances from a seismic sound source in order to determine the effect of seismic blasts on *Calanus spp.*, which is a key food source for commercially important fish. The results of this study found that immediate mortality of copepods was significantly different from controls at distances of 5 m or less from the airguns, and mortality one week after the airgun blast was significantly higher (9% relative to controls) in the copepods placed 10 m from the airgun blast, but not significantly different for those 20 m from the airgun blast. The increase in mortality (relative to controls) did not exceed 30% at any distance. Fields *et al.* (2019) concluded that these results suggest that seismic blasts have limited effects on *Calanus sp*. within 10 m of the blast and no measurable impact at greater distances. Fields *et al.* (2019) also commented on the results of McCauley *et al*. (2017), stating that it is difficult to reconcile the high mortality reported by McCauley *et al*. (2017) with the low mortalities reported in the body of earlier research and the results in the experiment that Fields *et al.* (2019) undertook.

Most recently, Vereides *et al.* (2023) also assessed the effects of exposure of seismic sound on copepods (*Acartia tonsa*) focussing on close range exposure ~6 m to air guns in the field. They reported similar findings to Fields *et al.* (2019) in that the exposed copepods exhibited low immediate mortality rates of ~14% *cf.* 4% at the control sites. Delayed mortality was also measured and almost all copepods exposed to seismic sound were dead after six days compared to <50% death in copepods after six days at control sites (it is noteworthy that no feed was added to any treatments post-exposure). Effects on growth and development of copepods was also assessed with exposed copepods exhibiting growth rates approximately 60% lower than for copepods at control sites. Hernes Vereides *et al*. (2023) highlighted that their results were in line with many previous studies on zooplankton and provided further evidence that seismic sound has a limited effect on zooplankton and that when effects occur, they tend to arise within approximately 10 m from the seismic sound source. The authors also made reference to the McCauley *et al*. (2017) finding of an immediate mortality rate of 50% at >1 km stating that this was not replicated within their study which reported an immediate mortality of ~14% at 6 m from sound source.

7.2.2.2.1.1 Plankton UAM

As outlined in **Section 7.2.2.2.1**, there are only a few studies in which threshold criteria for plankton can be based on. Popper *et al.* (2014) cites many of the references and studies on potential impacts of noise emissions on fish eggs and larvae prior to 2014, and results in Day *et al.* (2016) for embryonic lobsters and Fields *et al*. (2019) for copepods align with those presented in Popper *et al.* (2014). These studies conclude that mortality and sub-lethal injury are limited to within tens of metres of acoustic sources. It is also worth noting that the criteria defined by Popper *et al.* (2014) have been extrapolated from simulated pile driving signals which have a more rapid rise time, and greater potential for trauma than pulses from an acoustic source. The results of McCauley *et al*. (2017) indicate the potential for effects at a longer range, and at levels of 178 dB PK-PK; however, as outlined above, Fields *et al.* (2019) noted that it was difficult to reconcile the high mortality reported by McCauley *et al*. (2017) with the low mortalities reported in the greater previous body of earlier research and their own experiment.

Based on the above, the threshold values from Popper *et al.* (2014) have been utilised as part of the UAM report (**Appendix B**) and are summarised within **Table 64**.

Table 64 Noise Exposure Criteria and Zones of Impact for Mortality and Potential Injury for Zooplankton, Fish Eggs and Larvae

Zooplankton, Fish Eggs and Larvae	Mortality and potential injury threshold levels	Maximum threshold distance (m)
Based on Popper *et al.*, (2014) for fish eggs and larvae	PK: >207 dB re 1 µPa	200
	SEL_{24hr}: >210 dB re 1 μPa^2.s	80

7.2.2.2.1.2 Duration and Extent of Zooplankton Exposure

Natural mortality estimates for zooplankton are generally high and variable. Tang *et al*. (2014) reviewed available research and reported zooplankton daily mortality rates of 11.6% (average minimum) to 59.8% (average maximum) but in some instances these authors found that 100% of samples died within a day. Predation accounted for some of this mortality; however, non-predatory factors (e.g. inadequate food resources, physical exposure or poor water quality and diseases/parasites) have been estimated to account for approximately 25% - 33% of the total mortality among marine copepods (Fuiman and Werner, 2002; Tang *et al*., 2014; Dubovskaya *et al*., 2015). In other studies, Houde and Zastrow (1993) estimated the mean mortality rate for fish larvae to be 21.3% per day, and Saetre and Ona (1996) estimated zooplankton mortality to be 5 – 15% per day.

Compared to the high (5 - 59.8%) natural mortality rates reported by the above studies, seismic-related reductions in zooplankton abundance associated with the Otway Basin 3D MC MSS are likely to be very low and cumulative effects of natural mortality and seismic-related mortality are likely to be within the range of natural mortality rates observed in other studies. This assessment is consistent with Richardson *et al*. (2017) who reported seismic impacts on zooplankton will only be discernible locally and are expected to be insignificant at a regional scale given the natural spatial and temporal variability in plankton abundance, and the very high rates of natural mortality.

In addition to the inconsequential seismic mortality rates in comparison to natural mortality rates, it is also important to consider the following points when assessing the predicted impact of the Otway Basin 3D MC MSS on zooplankton:

- The simulation by Richardson *et al*. (2017) showed that, following exposure, there was a rapid recovery (on the scale of days) of zooplankton populations due to their fast growth rates and the dispersal and mixing of individuals from inside and outside of the impacted region. The high energy nature of the offshore marine environment in the OA will help promote rapid recovery of zooplankton populations on account of dispersal, mixing and replenishment by currents from non-impacted areas. Due to the short time required for zooplankton populations to replenish following any reductions in biomass that may occur due to the Otway Basin 3D MC MSS, any effects will be temporary and short-lived and are not expected to have any ecological consequences on zooplankton populations;
- In addition to the findings of Richardson *et al.* (2017) which focussed on population and regional level zooplankton responses, the findings of Day *et al.* (2021) showed that there is a recovery threshold for exposed zooplankton and thus significant potential for recovery in sub-lethally affected zooplankton in proximity to the sound source.
- Due to the magnitude of such localised impacts being negligible (based on **Table 64**), it is not expected that these impacts will be discernible at a regional scale, especially when considering the variability and scale of plankton and spawning biomass in the wider region; and
- Zooplankton occurring within the OA will not be evenly distributed. They will move in accordance with the currents and are likely to exhibit considerable spatial patchiness therefore zooplankton are less likely to be impacted multiple times by a seismic gun.

Overall, there is the potential for localised temporary impacts on zooplankton as a result of the Otway Basin 3D MC MSS; however, population recovery is expected within days after the Otway Basin 3D MC MSS has ceased and no lasting ecosystem population impacts are expected based on the findings detailed above. Based on the scientific literature provided above, the Otway Basin 3D MC MSS will not have any temporal or spatial impacts that are serious or irreversible on any areas that are known to have high productivity within the OA at certain times of the year. In addition, any impacts to local zooplankton populations as a result of the emitted sound levels from the Otway Basin 3D MC MSS will be localised, temporary and recoverable in the short-term.

7.2.2.2.1.3 Scallop Larvae

In 2002, ESSO Australia commissioned a study conducted by the Victorian Marine and Freshwater Institute to address, amongst other things, the concerns of Bass Strait scallop fishermen that seismic activities might increase the mortality of larval scallops (Parry *et al*., 2002). This study tested the effects of seismic surveys on plankton, with special attention to the effects on bivalves (including scallop) larvae. A before-after-control-impact (**BACI**) survey design was used whereby plankton samples were collected before and after (immediately behind and 2 km away from) the transit of the seismic survey vessel (maximum source strength was 211 dB re 1 µPa @ 1 m at a frequency of 50 Hz). The results showed that there was no significant difference between the number of bivalve larvae found in samples collected before and after the seismic vessel had passed. There was also no evidence that seismic exposure caused changes to planktonic taxa in the surface waters (up to 20 m depth) in Bass Strait. It is important to note that the number of bivalve larvae detected was low and therefore only a large impact on their abundance would have been detected (Parry *et al.*, 2002). However, other experimental studies suggest that impacts on plankton are unlikely to occur at distances of more than 10 m from an acoustic source (Parry *et al*., 2002; see **Section 7.2.2.2**).

In another study, New Zealand scallop larvae were experimentally exposed to seismic pulses (160 dB re 1 µPa @ 1 m at 3 second intervals) in order to assess the effect of noise on early larval development (Aguilar de Soto *et al*., 2013). Within one hour of fertilisation scallop larvae were suspended at a depth of 1 m within a tank containing seawater. The effects of noise exposure at 24 to 90 hours of development were investigated and compared to a control group (which experienced no anthropogenic noise). Of the experimental larvae, 46% showed abnormalities in the form of malformations, such as localised bulges in soft tissues. No malformations were observed within the control group. This study provided the first evidence that continual sound exposure causes growth abnormalities in larvae.

Despite indicating larval vulnerability, it is important to put the results of the Aguilar de Soto *et al*. (2013) study into context. The experimental study was restricted to newly fertilised larvae that were exposed to sound pulses of 1.5 seconds duration every three seconds (over a period of 24 – 90 hours). In contrast, the Otway Basin 3DMC MSS will have a shot-point interval of 5.4 seconds and exposure time will be much shorter since the source is constantly moving and will pass most acquisition lines only once. This study used pulse duration of 1.5 seconds whereas the pulse duration for a seismic array is typically around 30 milliseconds.

Field-based studies carried out by Pearson *et al*. (1994) and Parry *et al*. (2002) have reported no evidence of delayed development, increased mortality, or reduced abundance in bivalve or decapod larvae when exposed to more realistic noise impulse scenarios.

The most proximal scallop fishery to the OA is the Bass Strait scallop fishery, which has a 3,000 tonne catch limit, and is located approximately 285 km to the east. Although this fishery is a reasonable distance away from the proposed activity, during consultation, it has been reported that the spawn that feed this fishery come from VIC/South Australia waters. Scallops reproduce via broadcast spawning, whereby individuals release sperm first followed by eggs (Minchin, 2022). Once external fertilization has occurred, the larvae stay in the water column for 30 days (Ovenden *et al*., 2016) before settling, assuming the sediment is suitable for their recruitment. Spawning for the Australian commercial scallop (*Pecten fumatus*) occurs in winter/spring (June to November) (Dredge *et al*., 2016; Sause *et al*., 1987) and peak settlement of larvae occurs in mid-late September (Hortle and Cropp, 1987). There is some very limited evidence for a smaller, autumn peak in spawning for scallop populations in Bass Strait (Coleman, 1988). The timing of spawning (winter/spring), and the timing of the proposed survey (most likely October to March) is at the end of the peak spawning season (September) and towards the end of the peak larval settlement period (mid-late September). So, with the 30-day period that the scallop larvae remain in the water column and the commencement of the Otway Basin 3D MC MSS, it is likely that most of the scallop larvae will have settled to the seabed, mostly in the coastal waters, inshore of the OA. As such, and in accordance with Day *et al*. (2016a) and the zooplankton discussions in **Section 7.2.2.2.1,** the residual risk to scallop larvae arising from acoustic disturbance during the Otway Basin 3D MC MSS has been assessed as **Low** (*Minor* x *Possible*).

7.2.2.2.1.4 Rock Lobster Larvae

Due to the logistical and financial difficulties of field-based experiments, most scientific investigations into the impact of seismic outputs on rock lobster (and other marine invertebrate) larvae have been confined to laboratory environments. While these laboratory experiment cannot exactly replicate real-world conditions, they still provide useful information on test species response to seismic sound sources. Field based studies are more likely to be representative of the real-world impacts of MSS. In relation to rock lobster larvae there are some recent field experiments that have provided useful information on the real-world impacts of seismic sound sources.

As already summarised in **Section 7.2.2.2.1**, Day *et al.,* (2021) tested the effects of a commercial MSS on southern rock lobster (*Jasus edwardsii*) larvae (puerulus) and post-larval juveniles at a site off Lakes Entrance, VIC. Puerulus were randomly assigned to either Control (not exposed to air gun signals) or E0 (exposed to air gun signals at a nominal range of 0 m from the vessel sail line) treatments. Juveniles were assigned as above for Puerulus but also to a E500 treatment (exposed to airguns at nominal range of 500 m). All treatments lay at between approximately 50 m and 60 m depth. The seismic vessel towed three 2,820 in^3 seismic sources at 8 m depth, one 435 m astern the vessel on the vessel sail line and one 100 m either side of this source. Behind the air gun array sources, 12 x 7.3 km long seismic streamers were towed spaced across 1.3 km, which carried the hydrophones that recorded the seismic signals. Each seismic source was operated alternatively at a median 5 s rate (mean 5.3 s).

Once the MSS was completed lobsters were recovered and tested for dorsoventral righting reflex which is a complex reflex requiring sensory input to mediate neuromuscular coordination and is tested by quantifying the time taken to return to a dorsum-up position after being placed in a ventral side up position. A subsample of rock lobsters was returned to the laboratory and held until they had moulted twice (juveniles) or three times (puerulus) to calculate intermoult duration for each lobster. The moulting process is physiologically stressful and can be delayed in due to external stressors, thus making intermoult duration an important measurement of physiological condition as well as a marker of growth and development (Day *et al.,* 2017).

Day *et al.,* (2021) found that exposure to a SEL of 227 - 229 re 1µPa^2.s:

- Did not result in any elevated mortality for either puerulus or juveniles;
- Caused significant impairment of righting reflex for all treatments;
- After one moult the effects on righting reflex were largely undetectable for the more distant 500 m treatment, indicating that recovery is possible for sub-lethally exposed individuals at distances greater than 0 m from the sound source; and
- Intermoult time periods increased significantly for the 0 m treatment for puerulus (and observationally for juveniles, though abundances were too small for statistical analyses) indicating potential effects on development and growth but the authors state that that exposure to the sound source was not a definitive cause of this observation.

The specification of the seismic survey carried out in Day *et al.,* (2017) is not dissimilar to that proposed here. Both are triple source with the proposed air guns being 3,480 in^3 (*cf.* 2,820 in^3: Day *et al*., 2017). The proposed seismic sources will be towed at 8 m depth (*cf.* 7m: Day *et al.,* 2017). Behind the air gun array sources, up to 14 7.3 km long seismic streamers will be towed (*cf.* 12 x 7.3 km long seismic streamers spaced across 1.3 km: Day *et al*., 2017), which will carry the hydrophones that recorded the seismic signals. Each seismic source will be operated alternatively at a median 5.4 s rate (*cf* 5.3 s: Day *et al.,* 2017). The similarity in MSS specifications and relative geographic proximity of the proposed Otway Basin 3D MC MSS and Day *et al.* (2017) study mean that the results outlined here are highly relevant. These results broadly align with the bulk of pre-existing literature on the near-field effects of seismic sound exposure to zooplankton further demonstrating that effects of seismic exposure on rock lobster larvae are largely sub-lethal, temporary and localised, occurring in areas proximal to the sound source.

In 2016, Day *et al.* published an in-situ study (Day *et al*., 2016a,b) on the impact of seismic source exposure on the embryonic development of southern rock lobster (*Jasus edwardsii*) larvae. This experiment was conducted in Storm Bay in Southern TAS, over a shallow limestone reef platform with uniform depths of 10 – 12 m. Here, egg-bearing female rock lobsters were exposed to signals from three seismic source configurations at various distances (45 in^3 airgun and 150 in^3 air gun high pressure experiments, and a 150 in^3 low pressure experiment), all of which exceeded SELs of 185 dB re 1 µPa^2·s. The maximum and median cumulative SELs estimated in the three experimental regimes were 192 and 191 for the 45 in^3 experiment, 193 and 192 for the 150 in^3 low pressure experiment and 199 and 197 dB re 1 µPa^2·s for the 150 in^3 high pressure experiment.

Specifically, berried female rock lobsters were randomly allocated into control and exposed treatments and placed in situ in lobster pots. Seismic source runs were made starting at 1 – 1.5 km from the line of pots with the source run towards and over the pots, with total air gun exposures of 24.3, 17.2 and 23.3 minutes, for 126, 112 and 110 shots for the 45 in^3, 150 in^3 low pressure and 150 in^3 high pressure experiments. Control runs emulated the exposure runs with the source deployed and pressurised but not operated. Following the control and exposure runs, the lobster pots were recovered, and the rock lobsters were kept in holding tanks until hatching, which occurred a mean 87±2, 79±2 and 79±3 days post-exposure in the 45 in^3, 150 in^3 low pressure and 150 in^3 high pressure experiments, respectively.

Once hatched, the effects of the exposure treatments on rock lobster embryonic development were assessed by examining the number, morphology, energy content and competency of hatched larvae.

The results showed that:

- There were no mortalities of the adult berried female lobsters in either control or exposed treatments for any of the three experiments;
- All females had successful hatches with no incidence of loss or removal of the egg bundle;
- Lobsters in both treatments over all three experiments hatched over the course of a 5 – 6-day period, with a peak in the number of larvae hatched around days 3 – 4;
- There were no morphological abnormalities in any of the hatches;
- There were some differences in larval body length between control and exposed larvae in the 45 in^3 experiment (exposed larvae were approximately 1.5% longer than control larvae), but not in the other two experiments;
- There were no differences in larval width between treatments for all three experiments;
- There were no differences in length-to-weight and width-to-weight ratios between treatments for all three experiments;
- There were no significant differences between the dry masses of any of the treatments;
- Larval energy content did not differ between treatments in any of the exposure levels; and
- There was no difference in larval competency (i.e. activity test results) between treatments in any of the exposure levels.

The results dismiss concerns that exposure to seismic signals will result in egg bundle loss, decreased fecundity, comprised larvae and/or morphological abnormalities. The concern that exposure will result in abnormal larval morphology, cannot be immediately dismissed, as the exposed larvae from the 45 in^3 experiment were found to be significantly longer than control larvae. However, the larval size falls within the range for Stage I larval length of *J. edwardsii* (Lesser, 1978) so it is likely that the observed length difference is not biologically significant.

Overall, the results of the Day *et al.* (2016a, 2016b) study found no differences in the quantity or quality of hatched rock lobster larvae and these authors concluded that seismic air gun exposure during early-stage embryonic development does not negatively affect rock lobster larvae. However, other life stages were not investigated in this study so concern over the potential effects of seismic outputs on other life stages cannot be dismissed.

The UAM study (Welch *et al.,* 2023) has shown that threshold for cumulative exposure (SEL_{24h}: 210 dB re 1 µPa^2·s) for fish eggs and larvae (a component of zooplankton) will not be reached at the seabed in the area where 3D MSS will be taking place. This means that on the seabed in the majority of the AA any berried female rock lobsters, their eggs and resulting larvae are extremely unlikely to be affected by the Otway Basin 3D MC MSS.

2D acquisition will be carried out in a very small relatively shallow (94 m – 500 m) proportion of the AA (73 km^2, or 0.16% of the AA). The UAM did not assess the potential for cumulative exposure thresholds to be reached at the seabed in this area. It is possible that in shallower parts of the 2D MSS area the cumulative threshold (SEL_{24h}: 210 dB re 1 µPa^2·s) could be reached at the seabed. If cumulative exposure thresholds were reached within the 2D AA it is possible that berried females, eggs and subsequent larvae could be affected. In addition, the results of the Day *et al.* (2021) study have shown that while effects on proximal rock lobster larvae and juveniles are likely (if they are present) they will be sub-lethal, temporary (either based on an individual's ability to recover, or based on the population recovery time of zooplankton more generally (Richardson *et al.,* 2017)) and restricted to within a localised area around the sound source.

Based on the results of Day *et al.* (2016 and 2021) the residual risk to rock lobster larvae arising from acoustic disturbance during the Otway Basin 3DMC MSS has been assessed as **Low** (*Minor* x *Likely*).

7.2.2.2.1.5 Overall Ecological Impacts of Plankton Exposure

Zooplankton are an important food source to many fish species and cetaceans in the ocean, and any significant reductions in zooplankton biomass has the potential to affect the wider food chain due to cascading effects. This is particularly important to consider in sensitive areas like those associated with the West Tasmania Canyons KEF and BIAs, which overlap with the OA (**Section 4.4.3**).

Ecological effects of reduced zooplankton biomass may include changes in the distribution of species which rely on zooplankton as a food source, such as pelagic fish, seabirds, and some marine mammals, where they temporarily have to relocate to another foraging ground to find the food they require for survival.

For example, distributional changes in zooplankton (particularly krill) flow could have effects on taxa that prey on plankton or are reliant on lower food chain predators of zooplankton as a prey source. Catch rates of commercially fished species could also conceivably change in response to flow-on effects associated with changes in the abundance or distribution of zooplankton prey.

Based on the extensive literature reviews, the weight of the scientific literature supports that any potential flow-on effects to marine food webs through impacts on zooplankton are expected to be spatially restricted. For the Otway Basin 3D MC MSS, the UAM (**Table 64**; **Appendix B**) predicts the zone of impact for zooplankton to extend 140 m from the seismic source for fish eggs and larvae (based on Popper *et al*., (2014)). Based on the results of the Day *et al.* (2021) some temporary, sublethal effects could occur for certain components of zooplankton at up to 500 m from the acoustic source. Baseline conditions can be expected to resume relatively quickly after survey completion (see Richardson *et al*., 2017) due to replenishment of zooplankton back into the area.

There are unlikely to be any wider ecosystem-related impacts as a result of cumulative natural and seismic-related mortality effects. Even after they die, zooplankton remain available as a food source for higher organisms as their carcasses remain in the water column for several days. If they are not consumed, they then fall to the seafloor and where they are available as a food source for benthic organisms (Kirillin *et al*. 2012; Tang *et al*. 2014).

Overall, the residual risk to zooplankton physiology on a population level arising from acoustic disturbance during the Otway Basin 3D MC MSS has been assessed as **Negligible** (*Negligible* x *Likely*).

7.2.2.2.2 Benthic Invertebrates

Research into the relationship between sound and its effect on benthic invertebrates is ongoing, including the relevant metrics for both effect and impact. Available literature suggests marine benthic invertebrates are most sensitive to the vibrational component of sound, owing to a lack of anatomical structures involved in detecting the pressure component of sound. Like elasmobranchs, marine invertebrates lack a gas-filled bladder and are thus unable to 'hear' the pressure changes associated with sound waves. Instead, marine invertebrates detect sound by sensing the particle motion component of sound in water and within seabed sediments through physiological structures such as statocysts, sensory hairs and muscles (Carroll *et al*., 2017). McCauley (1994) reported that for many benthic species, these receptors will perceive seismic acoustic outputs, but this will only occur within a few metres from the sound source.

Marine invertebrates can be free-living or sessile, are often localised to particular benthic microhabitats, and generally have lower mobility than pelagic species. Hence, they generally have a reduced ability to avoid acoustic emissions, and any potential associated impacts, by moving away. Studies investigating the physical and physiological impacts of seismic noise on marine invertebrates are relatively limited (Carroll *et al*., 2017). Where such studies exist, the acoustic signature and exposure scenarios applied are often not comparable to those of a typical (i.e. commercial) seismic survey. The findings of such studies are also highly variable and, in some cases, disparate. For example, exposure to noise has resulted in a few reports of immediate (Lagardère, 1982; McCauley *et al*., 2017; Fields *et al.,* 2019) or delayed mortality (Day *et al*., 2017). In addition to mortality effects, a range of physiological impacts have also been observed including damage to sensory systems (Day *et al*., 2019; Day *et al*., 2022), disruption to immune system function (Fitzgibbon *et al*., 2017), stress biochemistry (Payne *et al.*, 2008; Day *et al*., 2021) and changes to metabolic rate. Conversely, several studies have reported no significant effects (Przelawki *et al*., 2018; Day *et al.*, 2016). In summary, the available literature does not clearly define an appropriate metric or identify relevant levels (pressure or particle motion) for assessment. Despite this, current industry practices for investigation and determining impacts and risk associated with acoustic emissions for marine invertebrates have been determined based on pressure levels presented in the literature for three taxonomic groups including crustaceans, bivalves and sponges and corals.

Of particular relevance to the Otway Basin 3D MC MSS are impacts to decapods (crabs and shrimp), octocorals and sponges which inhabit the soft sediment and hard substrate, respectively, that comprise the OA (see **Section 4.5.2**). Whilst polychaete worms were identified as the most predominant invertebrate taxa within soft sediment habitats comprising license area AC/RL7 (ERM, 2012; O2 Marine, 2018), located in the western portion of the OA, the effects of seismic exposures on these organisms have not been studied. Hence, the precautionary principle applies, and it's assumed that polychaetes could experience worst-case effects analogous to those reported for other benthic invertebrate taxa.

Crustaceans

Crustaceans are the most studied marine invertebrate group with respect to impacts associated with low-frequency acoustic disturbance, such as that generated by seismic airguns (Carroll *et al.,* 2017), owing in-part to their economic value. Hence, studies are largely constrained to investigations of physical, behavioural, and physiological effects and their implication upon catch rates of commercially important decapod crustaceans (lobsters, prawns, crabs) (Edmonds *et al*., 2016). Experiments on lobsters indicate that the main vibration receptors are in the statocyst and the walking legs (Day *et al.,* 2019; Aicher *et al*., 1983). The statocyst controls the righting reflex in lobsters, the coordination of which plays a vital role in predator evasion.

The reported impacts of seismic exposure on crustaceans are highly variable, though none have found any evidence of increased mortality of adults or life history stages and no direct impacts to the survivorship of exposed larvae have been reported (Carroll *et al.,* 2017; Day *et al*., 2016; Day *et al*., 2022). Likewise, studies investigating the influence of seismic exposure on commercially important species (e.g., snow crab and southern red lobster) do not appear to support the anecdotal contention that MSSs negatively affect catch rates in the short or long term (Morris *et al*., 2018; Parry and Gason, 2006).

As described in **Section 7.2.2.2.1**, current literature does not clearly define an appropriate metric or identify relevant effects levels for noise assessments. Adopted industry practice effects levels for crustaceans associated with no effects and sub-lethal effects attributable to seismic emissions have been derived based on exposure of a limited number of species to a range of seismic signals of variable representativeness when compared to a commercial MSS. A summary of relevant studies and findings upon which the adopted industry practice effects levels have been derived are provided below.

Payne *et al*. (2008) conducted a pilot study on the effects of seismic sound exposure on various health indicators on American lobster. Adult lobsters were exposed to an acoustic source for 20 or 200 pulses at an average pressure of 202 dB re 1 µPa PK-PK or 50 pulses to 227 dB re 1 µPa PK-PK. Study subjects were located 2 m from the acoustic source. The study investigated potential changes to survival, food consumption, turnover rate, and serum biochemistry. No immediate or delayed mortality was observed, nor damage to mechano-sensory systems and the ability of lobsters to right themselves when turned over. However, there was evidence of a decrease in serum enzymes and increases in food consumption in the weeks to months post exposure, interpreted to indicate potential stress effects or osmo-regulatory disturbance. Whilst no impacts to long-term survival and population ecology were observed, the results indicate the potential for sub-lethal effects. On this basis, a PK-PK sound level of 202 dB re 1 µPa is broadly considered to be associated with no effect and therefore applied in the assessment.

To further understand the interactions between MSS and marine invertebrates, Day *et al*. (2016a, 2016b) investigated the effects of low frequency acoustic signals on adult rock lobsters, including egg carrying females. The study involved exposure of southern rock lobster to (up to four) passes of an active acoustic source, whilst placed in field sites consisting of comparable seabed morphology to the natural habitat of the subject species[15]. The study found that adult southern rock lobsters (*Jasus Edwardsii*) which were exposed to seismic sound levels up to a maximum of 212 dB re 1 µPa PK-PK did not show an increase in mortality and no lethal effects to embryos were observed. Evidence of sub-lethal effects in adult, exposed, lobsters included impairment of reflexes involved with tail control and righting, damage to the sensory hairs of the statocysts (balance organ), a reduction in the number of haemocytes (indicative of reduced immune response function). Though the study reported some improvement to condition and righting reflexes across the monitoring period (120 days post-exposure), the effects to the statocysts appeared somewhat persistent being observable at 365 days post-exposure and post-moult. There was no reported difference in fecundity between the control and exposed lobsters. Likewise, hatched larvae were found to be unaffected. There was no reported difference in the number and condition of hatched larvae between the control and exposed lobsters, suggesting that exposure during early embryonic stage did not impair embryo development.

Uniquely, the study found that control subjects collected from Crayfish Point Reserve, a site which experiences substantial levels of anthropogenic noise, showed a level of statocyst damage equivalent to that of seismic exposed treatments, including 'noise-naïve' subjects. Further, exposure to air gun treatments did not result in additional statocyst damage in the exposed treatment relative to the controls and there were no significant differences in righting time in these lobsters. The author concluded that the damage observed was pre-existing and not exacerbated by seismic exposure as a result of the experiment. Coupled with subsequent comparisons of the soundscape at each site, Day *et al*. (2022) contends that lobsters at Crayfish Point Reserve demonstrated an ability to cope with or adapt to mechanosensory damage arising from noise exposure. Long-term monitoring of lobsters at Crayfish Point Reserve suggests the population has reached carrying capacity (Kordjazi *et al.,* 2015), indicating the observed mechanosensory damage has not resulted in negative ecological impacts. Instead, the population is perceived to be thriving. Day *et al*. (2019) further examined the impacts of MSSs on the physiology of southern rock lobster species. Exposure experiments were carried out at the seabed, in a field setting selected to emulate the natural habitat (seabed type and water depth) of the study species. The study found that adult southern rock lobsters (*Jasus Edwardsii*) which were exposed to seismic sound levels up to a maximum of 209 - 212 dB re 1 µPa PK-PK did not show an increase in mortality, even at close proximities to the sound source. However, there was evidence of sub-lethal effects occurring following seismic sound exposure; specifically, impairment of reflexes involved with tail control and righting, damage to the sensory hairs of the statocysts, and a reduction in numbers of haemocytes. Reflex impairment and statocyst damage persisted up to 365 days post-exposure and did not improve following moulting. Ecological impacts were not evaluated as part of the study.

Life-history stage is a critical factor for considering impacts upon broadcast spawning marine invertebrates which rely on the production of many offspring to maintain recruitment of adult populations and these potential impacts have been covered in Section **7.2.2.2.1**.

[15] Of note, is that field sites were very shallow (10 to 12 m) and are not considered representative of a typical environment in which MSS would be undertaken.

Though marine invertebrates are most sensitive to the vibrational component of sound, rather than sound pressure, it is not clear what level of particle motion relates to an adverse effect. Therefore, where available, sound level thresholds have been used to inform the UAM (Welch *et al*., 2023). Whilst no published threshold criteria currently exist to enable an evaluation of potential mortality or lethal injury effects on crustaceans, a PK-PK sound level of 202 dB re 1 µPa (per pulse) from (Payne *et al*., 2008) is considered to be associated with no effect and therefore adopted for the purpose of the assessment. Results were also compared against PK-PK sound levels ranging from 209 -213 dB re 1 µPa PK-PK determined by Day *et al.* (2016a, b) and Day *et al*. (2019) to result in potential sub-lethal effects (see **Appendix B**).

Bivalves

As is the case for crustaceans, studies undertaken on bivalves are largely constrained to commercially important taxa such as scallops and oysters. Recent Australian studies have focussed on southern scallops, *Pecten fumatus*, and found no evidence of immediate mortality or change in condition following exposure to seismic disturbance. However, sub-lethal effects to scallops were observed, including a compromised capacity for homeostasis and potential immunodeficiency over acute (hours to days) and chronic (months) timescales following exposure (Day *et al*., 2016b; 2017).

Day *et al*. (2016b; 2017) concluded that repeated exposure to seismic disturbance resulted in physiological damage, changes in behaviour and reflexes and increased risk of mortality, though not beyond naturally occurring rates of mortality. Injured scallops did not recover over the four-month period of the experiment. The authors reported that, compared with unexposed scallops, the daily mortality odds were found to be 0.1%, 1.2%, and 1.3% higher in scallops exposed to 1, 2 and 4 acoustic passes, respectively. Though the size of the air gun appeared to have no effect (Day *et al*., 2017). Uniquely, Day *et al*. (2017) measured the response of *Pecten fumatus* to ground roll acceleration associated with different experimental regimes as a proxy for particle acceleration. As particle motion is the more relevant metric to invertebrate sensory systems, the study provides novel insight into bivalve response to seismic disturbance.

In contrast, a study conducted by Przeslawski *et al*. (2018) found no evidence of increased scallop mortality, or effects on scallop shell size, adductor muscle diameter, gonad size, or gonad stage attributable to exposure to seismic disturbance. However, this study did not examine any long-term sub-lethal effects.

No published threshold criteria currently exist to enable an evaluation of potential mortality or lethal injury effects on bivalves. Likewise, the literature does not present a sound level associated with no impact. Consequently, the maximum measured particle acceleration reported within Day *et al*. (2017) of 37.57 ms^{-2} has been adopted to represent the level of acoustic disturbance known to elicit reduction in physiological condition for the purpose of this assessment.

Sponges and Corals

There is limited published literature on the potential impacts of seismic noise on hard and soft corals and sponges. Unlike other faunal groups such as cetaceans, currently there is no peer-reviewed criteria against which potential noise impacts to corals and sponges can be assessed.

The primary forms of physiological damage of corals due to exposure to high amplitude sound are understood to be: (1) breaking of the coral skeleton that could also damage the polyp tissue, and (2) rupture or tearing of polyp tissues (Hastings, 2008). The forces required to cause such damage were predicted by Hastings (2008) to be in excess of 260 dB re 1 µPa PK-PK.

Battershill *et al*. (2008) and Heyward *et al*. (2018) investigated the effects of the Woodside Maxima 3D MSS on hard corals in water depths of approximately 40 – 60 m within south Scott Reef lagoon. Corals received maximum sound pressure levels of 226 dB re 1µPa PK. No mortality, damage to soft tissue or skeletal integrity, visible signs of stress, change in abundance or community structure was detected immediately after, and up to four months following exposure. Soft corals were also examined, with particular notice taken of soft coral morphology and polyp extension immediately after seismic passes. No change on soft coral abundance was detected and there was no evidence of a behavioural response, such as polyp withdrawal or flaccidity (Battershill *et al*., 2008; Heyward *et al*., 2018).

Heyward *et al*. (2018) monitored the condition of Scleractinia corals at South Scott Reef, within the North West Marine Region, before and after a 3D MSS which involved a maximum peak sound level of 226 dB (i.e., 226 dB re 1 µPa PK) at the coral monitoring sites. There were no observable impacts to coral mortality, skeletal damage or visible signs of stress immediately after and up to four months following the acoustic disturbance event. Similarly, there was no evidence of a behavioural response, such as polyp withdrawal or flaccidity in the soft corals assessed. While not included as a test taxa in Heyward *et al.* (2018), for the purposes of this assessment of effects, sponges are considered together with soft corals because they are similar in that both have a similar density to water and do not have solid skeletal structures that could be damaged by pressure changes as a result of high-amplitude noise.

In lieu of published threshold criteria in Heyward *et al*. (2018), a PK sound level of 226 dB re 1 µPa (per pulse) is adopted for the purpose of the assessment in the UAM (Welch *et al.,* 2023). Importantly, this is not a threshold above which impacts are expected to occur, but a level at which no short term or long-term effects were observed.

7.2.2.2.2.1 Benthic Invertebrate UAM

As outlined in **Section 7.2.2.2.1**, there are few studies upon which threshold criteria for benthic invertebrates can be suitably developed. Based on the above, the threshold values used to inform the UAM report (**Appendix B**) and corresponding threshold distances are described in **Table 65**.

Table 65 Noise Exposure Criteria and Zones of Impact for Mortality and Potential Injury for Crustaceans, Bivalves and No Effect Threshold for Corals/Sponges

Benthic Invertebrates	Potential sub-lethal effects threshold levels	Maximum threshold distance (m)
Based on Day *et al*. (2019) and Day *et al*. (2016) for crustaceans	PK-PK: 209 - 212 dB re 1 µPa	421
Based on Day *et al.* (2017) for bivalves	37.75 ms^{-2}	10.5
	No effect threshold level	**Maximum threshold distance (m)**
Based on Payne *et al*. (2008) for crustaceans	PK-PK: >202 dB re 1 µPa	778
Based on Heyward *et al.* (2018) for corals and sponges	PK: >226 dB re 1 µPa	11

The results of the UAM indicate that where 3D MSS activity occurs in the AA:

- The adopted criteria of 202 dB re 1 µPa PK-PK for crustaceans, which is a minimum level that is representative of no effects, was not detected at horizontal distances greater than 489 m (at 674 m depth) and 512 m (at 569 m depth) from the 3,480 in^3 source;
- The adopted criteria of 209 - 213 dB re 1 µPa PK-PK for crustaceans, which is representative of possible sub-lethal effects for crustaceans, was not detected at horizontal distances greater than 105 m (at 674 m depth) and 157 m (at 569 m depth) from the 3,480 in^3 source;

- The adopted criteria for particle motion of 37.57 ms^{-2}, the threshold for potential reduction in physiological condition for bivalves, was not detected at any distance from the 3,480 in³ source acoustic source for the modelled scenarios; and
- The adopted criteria of 226 dB re 1 µPa PK, which is the threshold for no effects for sponges and coral, was not detected at any distance from the 3,480 in³ acoustic source.

The results of the UAM also indicated that where only 2D seismic survey activities occur in the AA:

- The adopted criteria of 202 dB re 1 µPa PK-PK for crustaceans, which is a minimum level that is representative of no effects, was not detected at horizontal distances greater than 676 m (at 220 m depth) from the 3,480 in³ source;
- The adopted criteria of 209 - 213 dB re 1 µPa PK-PK for crustaceans, which is representative of possible sub-lethal effects for crustaceans, was not detected at horizontal distances greater than 238 m (at 220 m depth) from the 3,480 in³ source;
- The adopted criteria of 226 dB re 1 µPa PK, which is the threshold for no effects for sponges and coral, was not detected at any distance from the 3,480 in³ acoustic source.

7.2.2.2.2.2 Sub-lethal Effects and Potential Effects

Given the importance of proximity to the acoustic source in determining potential effects, the depth of the AA is a critical consideration regarding the potential effects of seismic activities on benthic invertebrates. The proportion of the AA in which 3D MSS activities occur is 500 m deep at its shallowest point, with >99% of AA area lying at depths greater than 700 m depth. 2D MSS activities only will be carried out in a small (73 km^2 or 0.16%) shallow proportion of the AA.

The thresholds provided in **Table 65** are a guide to potential distance-based effects thresholds for high amplitude noise for four broad taxon groups from existing literature. As set out above, the thresholds in **Table 65** were compared to the UAM outputs. The following points cover effects of 3D MSS activities based on the consideration of UAM outputs and adopted effects thresholds in the context of seabed depths within the AA:

- The no-effect criteria for crustaceans of 202 dB re 1 µPa PK-PK, was modelled as being detectable at no greater than 512 m from the acoustic source. Given that this threshold represents no observed effects, any crustaceans inhabiting seabed areas at between 512 m and 500 m are considered to exist in areas that are on the outer margins of potential for sub-lethal effects. The area of the AA that lies at between 500 and 520 m is 2.5 km^2 which is 0.0005% of the total AA;
- The sublethal-effect criteria of 209 - 213 dB re 1 µPa PK-PK for crustaceans was modelled as being detectable at no greater than 157 m from the acoustic source. Given that the seabed is no shallower than 500 m in areas where 3D seismic activities will occur, this level of sub-lethal effects is highly unlikely to occur;
- No sub-lethal to fatal effects on molluscs were predicted to occur;
- No effects on corals and sponges were predicted to occur; and
- Given the response of organisms such as polychaete worms to seismic exposure have not been studied, and therefore the precautionary principle applies, it’s considered polychaetes could experience a range of sub-lethal effects.

Although only relevant to a very small proportion, approximately 73 km^2, or 0.16%, of the AA, the following points cover effects of 2D MSS activities based on the consideration of UAM outputs and adopted effects thresholds in the context of seabed depths within the relevant part of the AA:

- The no-effect criteria of 202 dB re 1 µPa PK-PK for crustaceans, was modelled as being detectable at no greater than 676 m from the acoustic source. Although this is a no-effects threshold, given the shallow depths in this area, crustaceans on the seabed have the potential to be being sub-lethally affected. This result should be considered alongside the predicted maximum distance for observed sublethal effects below;
- The sublethal effect criteria of 209 - 213 dB re 1 µPa PK-PK for crustaceans, was modelled as being detectable at no greater than 238 m (at 220 m depth) from the acoustic source. Given that this is an observed effect threshold, crustaceans on the seabed in areas shallower than 238 m are considered to be more likely to be sub-lethally affected than crustacea in deeper areas of the AA. Approximately 40 km^2 or 0.087% of the AA lies within this area of observed effects for crustaceans;
- No effects on corals and sponges were predicted to occur;
- Sub-lethal to fatal effects on molluscs were not predicted to occur; and
- Given the response of organisms such as polychaete worms to seismic exposure have not been studied, and therefore the precautionary principle applies, it's considered polychaetes could experience a range of sub-lethal effects.

The reported zones of potential impact for benthic invertebrates within the OA represent a considerably small portion of the available benthic habitat which is comprised mostly of soft sloping continental shelf edge sediments. There is no evidence that any significant reef structures or other seabed features which could host hotspots of benthic invertebrate diversity fall within any of the zone of potential impact (the area shallower than 512 m).

Despite the potential vulnerability to seismic emissions of benthic invertebrates due to their limited mobility, the studies that produced the effects threshold criteria adopted here concluded that mortality rates observed during exposure to seismic sound were within the natural range of variation which may be expected to occur due to changes in environmental conditions and anthropogenic stressors (Day *et al*., 2017; Payne *et al*., 2007, 2008). Further, populations exposed to anthropogenic acoustic disturbance have demonstrated an ability to cope with or adapt to sub-lethal effects arising from noise exposure, such as statocyst damage, and the capacity to recover from minor impairment to stress biochemistry and righting reflexes following exposure, except where impairment is incurred due to exposure at close range (Day *et al.*, 2021; Day *et al.,* 2016a, 2016b).

This information, in conjunction with the assessment of potential impacts to benthic invertebrate larvae completed in **Section 7.2.2.2** suggests there are no anticipated population level impacts or changes to ecological function and integrity as a result of exposure to the seismic source. Furthermore, available macrofauna survey data obtained through extensive literature reviews indicates that benthic faunal assemblages within the OA and surrounds are consistent with the broader region and do not include any endemic species.

On the basis that any potential sublethal effects to invertebrates in areas shallower than 512 m will be sub-lethal and temporary and that existing literature has found that effect levels at the effect thresholds adopted here potentially fall within the range of existing background variability, the level of consequence is considered minor and the likelihood that minor effects will occur in this area is likely.

Overall, the residual risk to benthic invertebrates arising from acoustic disturbance during the Otway Basin 3D MC MSS has been assessed as **Low** (*Minor x Likely)* and therefore, no impacts on populations or ecological function and integrity to benthic invertebrates are anticipated.

7.2.2.2.3 Bony Fish

All fish tested to date have displayed the ability to detect sound and vibration to some degree (Dale *et al.*, 2015), with sounds used by fish for communication, prey location, predator detection, and as a cue for orientation (McCauley and Cato, 2000). The hearing range and sensitivity of individual species of fish is however highly variable (e.g. Ladich and Fay, 2013) but fish generally hear best at low frequencies below 1 kHz (Ladich, 2000).

The hearing sensitivity of bony fishes varies between families and species. Hearing sensitivity is a function of specialised auditory structures in the inner ear (otoliths surrounded by an epithelium of hair cells) and, if present, the swim bladder (Finneran and Hastings, 2000; Nedwell *et al*., 2004). Otoliths are sensitive only to particle motion, while the swim bladder may provide an indirect route for sound pressure to reach the inner ear. The other main mechano-reception system in fish is the lateral line system, which runs along the side of the body of fishes and is more pronounced in some groups of fishes than others. The lateral line system responds to water displacements (particle motion) produced in the near-field of a sound source, as well as to tiny water currents set up by the fish's own motions (Nedwell *et al.*, 2004). Therefore, all fish are sensitive to the particle motion component of sound at close range from an acoustic source or other sound source, while some more specialised fishes with a swim bladder involved in their hearing are sensitive to sound pressure and are capable of detecting less intense noise and a wider range of frequencies compared to less-specialised groups of fish (Popper *et al*., 2014; Hawkins and Popper, 2016; Carroll *et al*., 2017).

Based on their morphology/hearing sensitivities, Popper *et al.* (2014) classified fishes and eggs and larvae into the following categories:

- Group I: Fishes without a swim bladder (or other gas chamber) that can sink and settle on the substrate when inactive. These fish are less susceptible to barotrauma than fishes with a gas-filled space as they can only detect particle motion at cloase range, not sound pressure changes. However, some tissue barotrauma is possible from exposure to extreme sound pressure changes;
- Group II: Fishes with swim bladders, but without a direct connection between the swim bladder and the inner ear. Hearing primarily involves particle motion at close range, not sound pressure; however, the presence of a gas-filled swim bladder means that some limited indirect detection of sound pressure may be possible, and the swim bladder is susceptible to barotrauma if exposed to rapid and intense pressure changes;
- Group III: Fishes with a swim bladder or other gas volume connected directly to the inner ear. These fishes are able to detect both sound pressure as well as particle motion, and are susceptible to barotrauma; and
- Fish eggs and larvae.

In marine fishes, the connection with the swim bladder and ability to detect sound pressure is understood to be present to some varying degree in the families Clupeidae (e.g. some herrings, sardines, pilchards and shads), Gadidae (e.g. true cods such as Atlantic cod and whiting), and some nearshore/reef species relevant to tropical Australia such as Pomacentridae (e.g. damsel fishes and clown fishes), Holocentridae (soldierfishes and squirrelfishes) and Haemulidae (e.g. grunters and sweetlips) (Nedwell *et al*., 2004; Braun and Grande, 2008; Popper *et al*., 2014; Popper and Hawkins, 2019). However, most marine fish species do not have this hearing specialisation.

A great many fish species possess a swim bladder or other gas-filled cavity but do not have a connection with their hearing. This is true of many demersal species in the region, as well as some tuna and billfish species. Fish species that lack a gas-filled cavity altogether, include elasmobranchs (e.g. sharks and rays), some flat fishes, some gobies, some tunas, mackerels and other pelagic and deep-sea species (Casper *et al*., 2012; Popper *et al*., 2014).

Of the many demersal species that occur on the outer continental shelf and the continental slope in this region, none are known to be sensitive Group III fishes (with a mechanical connection between the swim bladder and the inner ear, such as the Clupeidae or Gadidae families).

The current industry practise for investigating and determining impacts and risks associated with seismic emissions for fish are based on the Popper *et al.* (2014) classifications. At the time of developing the exposure guidelines, no quantified data on injury and mortality from seismic sources on fishes had been reviewed by Popper *et al*. (2014). Therefore, the Popper *et al.* (2014) exposure guidelines for mortality/potential mortal injury and recoverable injury for fishes exposed to acoustic emissions are based solely on data from pile driving conducted on predominantly temperate, freshwater fish species. Although MSSs and pile driving both produce impulsive sound, their sound characteristics are markedly different; pile driving impulses result in a more rapid rise time in sound pressure than seismic pulses and it is this rapid rise time that has the greatest potential for trauma (Hastings and Popper 2005; Popper *et al*., 2006).

7.2.2.2.3.1 Mortality and Mortal Injury

There are very few experimental examples of sound being sufficiently loud to result in death or mortal injury (i.e. delayed mortality) to fishes (Popper and Hawkins, 2018). There is no evidence for permanent hearing loss (PTS) in fishes; Popper and Hawkins (2018) suggest PTS may not occur in fishes since they can repair or replace sensory hair cells of the inner ear that have been lost/damaged.

Some experiments have recorded mortality following exposure to seismic emissions (e.g. Weinhold and Weaver, 1972; Matishov, 1992; Booman *et al*., 1996), however, in each case, mortalities occurred to caged fish at very close proximity (<2 m) to the acoustic source which is not representative of real-life exposure. A range of other experiments have not reported mortality following both realistic and unrealistic exposure to exposure levels (see McCauley *et al*. 2003a; Carroll *et al.*, 2017; Meekan *et al.*, 2021). Outcomes of previous seismic surveys completed along the west Australian coastline have not reported mortality of fish that are site attached or those that are considered pelagic from seismic data acquisition activities that have been undertaken. Similarly, these previous surveys have not recorded any substantial changes or impacts to commercial fisheries in these areas.

In many cases, the potential for physical injury and impairment impacts to occur may be dependent on fishes' abilities to move and avoid very high sound levels, and so the potential for physical trauma to occur is typically limited to situations where fish do not or cannot avoid such exposures (e.g. experiments involving captive fish that may not be representative of free-swimming fish). For example, Wardle *et al*. (2001) exposed free-swimming marine fish (juvenile saithe and Atlantic cod, adult pollock and adult mackerel) inhabiting a small reef system, to seismic airguns with a sound peak pressure of 195 – 218 dB re 1 µPa PK. No mortality was observed at these levels, even though some of these species are members of the Gadidae family and have a connection between the swim bladder and inner ear.

Juvenile fish may have similar hearing sensitivity as adults but are potentially more at risk of tissue damage than adult fishes as their smaller size means they have less inertial resistance to the particle motion effects of a passing sound wave in the water column (Popper and Hastings, 2009; Popper *et al*., 2016). However, to date, research into the effects of sound on fishes has been conducted on both juvenile and adult fish and, overall, the exposure thresholds and available research is considered broadly representative of both juvenile and adult stages.

Despite mortality being a theoretical possibility for fish exposed to seismic sound, Popper *et al*. (2014) and Carroll *et al*. (2017) note that physical injury leading to death from seismic sound exposure is likely to be limited to extreme cases and has not been observed in any free-swimming fishes exposed during an actual MSS.

Adopted industry practice levels associated with mortality or mortal injury attributable to MSSs vary between the four classifications as defined by Popper *et al.* (2014) (**Table 66**). These adopted industry practise levels were derived from the adoption of limits calculated following exposure of a limited number of fish species to pile driving activities that included exposure to 960 sound events at 1.2 sec intervals. As such Popper *et al.* (2014) suggested that these values are not definitive, are conservative, and should be treated as interim. The Canadian Science Advisory Secretariat completed a review of available literature and reported that based on available information, that fish mortality could occur at levels that exceed 220 dB (Worcester 2006), while acknowledging that adult fish mortality is considered unlikely from exposure to typical MSS arrays. Given that the reviewed literature reported that mortality and physical injury has only ever occurred within a few metres of the acoustic source, the sound exposure criteria proposed by Popper *et al.* (2014) for mortality and injury are considered to be highly conservative and provide a precautionary approach in the assessment of potential injury and mortality effects to fishes from exposure to underwater noise from MSSs.

In terms of the noise generated from the Otway Basin 3D MC MSS itself, and as discussed in **Section 7.2.2.3.2**, fish will typically move away from the source of acoustic emissions if they are uncomfortable with the noise, thereby minimising exposure and potential deleterious effects (Vabø *et al*., 2002; Pearson *et al*., 1992; Wardle *et al*., 2001; Hassel *et al*., 2004; Boeger *et al*., 2006). Due to the ability of fish to avoid exposure at various spatial scales (even those species that display site specific behaviours) it is likely that mortality would occur at levels that exceed the Popper *et al.* (2014) interim values and are likely to be >220 dB_{peak} (Worcester, 2006). As such it is considered that exposure to a threshold of > 220 dB_{peak} likely represents a more realistic while still conservative level of exposure to seismic emissions to assess the potential risk of fish mortality and potential mortal injury due to seismic activities associated with the current project. Despite the conservatism of the Popper *et al.* (2014) levels, that are currently considered industry practise and have been adopted for this assessment.

For fish without a swim bladder, the UAM (Welch *et al.,* 2023) indicates that the accepted sound pressure level for mortality and potential mortal injuries of 213 dB_{peak} (Popper et al., 2014) are not predicted at horizontal distances greater than 70 m from the acoustic source in waters ranging in depth between 114 m and 1,216 m. At 50 cm above the seafloor sound pressure levels of 213 dB_{peak} were predicted out to 75 m from the acoustic source (**Table 66**). Threshold levels of 207 dB_{peak} for mortality and potential mortal injuries for Group II (fishes with swim bladders whose hearing does not directly involve the swim bladder or other gas volumes) and Group III fishes (fishes whose hearing does directly involve a swim bladder or other gas volume) as well as fish eggs and larvae are not predicted at horizontal distances greater than 150 m from the acoustic source across all water depths modelled (114 m – 1,216 m). At 50 cm above the seafloor sound pressure levels of 207 dB_{peak} were predicted out to 156 m (**Table 66**).

Table 66 Predicted onset distances (single pulse and SEL_{24h}) for the mortality of fish (Groups I, II, and III) and fish eggs and larvae, both within the water column and at the seafloor

	Mortality and potential mortal injury	
	Per Pulse (peak)	SEL_{cum}
Group I: Fishes without a swim bladder that can sink and settle on the substrate when inactive	>213 dB	>219 dB
Maximum modelled distance (horizontal) (at model scenario depth) (m)	70 (114 – 1,216)	110
Maximum over seafloor modelled distance (at model scenario depth) (m)	75 (114)	-
Group II: Fishes with swim bladders whose hearing does not directly involve the swim bladder or other gas volumes **Group III:** Fishes whose hearing does directly involve a swim bladder or other gas volume **Eggs and larvae**	>207 dB	Group II, fish eggs and larvae: 210 dB Group III: 207 dB
Maximum modelled distance (horizontal) (at model scenario depth) (m)	150 (114)	110 (for both Group II (incl. fish eggs and larvae) and Group III)
Maximum over seafloor modelled distance (at model scenario depth) (m)	156 (114)	-

Site attached fish (those that rely on benthic habitats) may have limited ability to move away from acoustic emissions. Fishes within the OA that are generally considered site attached including a range of commercially targeted species such as flathead, orange roughy, pink ling, eastern school whiting, blue-eye trevalla, ribaldo, gummy shark, and sawshark would be able to undertake movements to avoid acoustic emissions that may cause mortality or mortal injury. Despite the potential vulnerability of site attached fish with limited mobility to acoustic emissions, assemblages that have been exposed to anthropogenic acoustic disturbances have been reported to exhibit high levels of resilience and quick recovery following exposure (Lefèvre and Bellwood, 2015; Syms and Jones, 2000).

The biomass and diversity of site attached fishes is typically greatest in the photic and upper mesophotic zones (<60 m depth) which subsequently decreases with increasing depth (Abdul Wahab *et al.*, 2018). Moreover, deeper areas (up to 60 m depth) that are proximal to reef and shoal habitats typically contain a higher abundance and diversity of fish than areas of similar depth that are not associated with reef and shoal habitats (Abdul Wahab *et al.*, 2018). Although the AA overlaps with the West Tasmania Canyons KEF, this KEF has not been identified as an area of increased fish biomass/diversity but is instead designated a KEF on account of the benthic invertebrate communities present. Due to the water depths involved within the AA, site attached fish are not at increased risk of mortality or mortal injury from the Otway Basin 3D MC MSS.

Pelagic species within the OA including those that are targeted and retained in commercial fisheries (e.g. SESSF, SPF, ETBF, SBTF) include various species of mackerel, tuna and billfish, blue grenadier, and redbait (see **Section 4.7.3**). These species typically do not have a large swim bladder if present at all and as such mortality and mortal injury is based on conservative industry practice levels predicted to occur within a maximum (per pulse) horizontal distance of 70 m from the acoustic source (**Table 66**). Species that inhabit the pelagic environment can avoid areas that exceed current conservative industry practise levels. Moreover, as the acoustic source is moving pelagic fishes would have a period as the source approaches to avoid the area and thus avoid exposure to levels that may cause mortality or mortal injury.

In the 2D Tie Line AA that extends onto the continental shelf and minimum water depths of approximately 115 m, the maximum ranges on the seabed where injury may occur are 75 m for Group I fishes (no swim bladder) and 156 m for Group II and Group III fishes. It is again highlighted that the Popper *et al.* (2014) thresholds for injury and mortality are likely to be highly conservative, and studies have indicated that much higher received sound levels up to 246 dB re 1 µPa PK have not resulted in injury or mortality. The potential for mortality and injury is therefore likely to be limited to within very close proximity of the acoustic source. Importantly, the potential for mortality and injury to occur is dependent on fishes' abilities to move and avoid very high sound levels. The demersal fish assemblages that are expected to be present on the outer continental shelf are generally wide-ranging, free-swimming species. The available studies on the behaviour of both captive and free-swimming fishes exposed at close range to MSSs (see **Section 7.2.2.3.2**) generally indicate an increased level of startle response and increased swimming activity with increased sound levels or in response to exposure at close range. It is highly unlikely that fishes will remain within range of the acoustic source where mortality/injury can occur. Injury or mortality may only occur in the immediate vicinity of the acoustic source in the unlikely event that the acoustic source commences operation suddenly at full power without the opportunity for fishes to avoid increasing sound levels (i.e. no soft-start management measures). However, soft-start measures will be implemented (as detailed in **Section 3.5.3** and **Table 84**). Therefore, demersal fishes in the AA can reasonably be expected to exhibit an avoidance response and swim away from the approaching acoustic source before sound levels approach levels that may result in injury or mortality.

It is considered that based on the results of the UAM (Welch *et al*. 2023), and the limited and at times contradictory evidence to suggest acoustic emissions can result in fish mortality, that the consequence of acoustic emissions on fishes (both site attached and pelagic) including commercially important species is considered to be minor; with no detectable adverse effects on fish populations and rapid recovery from any impact is expected to occur. it is considered that fish mortality associated with exposure to acoustic emissions may occur in exceptional circumstances. As such, the residual risk based on implementation of identified mitigation measures of fish mortality due to exposure to acoustic emissions associated with the Otway Basin 3D MC MSS has been assessed as **Low** (*Minor x Rare*).

7.2.2.2.3.2 Fish Egg and Larvae Mortality

Fish eggs and larvae have been reported to be susceptible to mortality or mortal injury when exposed to seismic emission levels of >207 dB_{peak} and >210 dB_{SEL} (Popper *et al.,* 2014). Throughout the OA there are no known specific spawning aggregation sites critical for the ongoing viability of fish species present including species that are targeted and retained in commercial fisheries that operate within the area. These species are generally widely distributed and have extended spawning seasons (e.g. blue warehou and blue grenadier spawn June to September, striped trumpeter spawn July to October, and snapper spawn August to November (see **Table 37**). Within these spawning periods individuals typically spawn multiple times and generally display broadcast spawning strategies.

Spawning multiple times over an extended spawning period can offset potential risks and high inherent levels of mortality experienced by fish eggs and larvae. Natural rates of mortality experienced by fish eggs and larvae can be very high in some cases greater than 50% per day and often more than 20% per day (Houde and Zastrow 1993; Tang *et al.*, 2014). Spreading reproductive investment and output reduces the potential that an individual batch of eggs and larvae experience adverse environmental conditions, predation, or exposure to deleterious effects at both local and regional scales.

Under a 'worst-case' scenario Sætre and Ona (1996) reported that mortality rates for fish larvae and fry for five fish species (cod, saithe, herring, turbot and plaice) due to exposure to seismic emissions is likely to represent 0.45% of the total larvae population. Sætre and Ona (1996) concluded that mortality rates caused by exposure to acoustic source sounds are so low compared to natural mortality that the impact from MSSs must be regarded as insignificant (Sætre and Ona, 1996). In addition, as both the source of seismic emissions and the water body in which fish eggs and larvae are present are moving, exposure of fish eggs and larvae to industry practise levels that may result in mortality or mortal injury would at worst occur over a very short period for eggs and larvae originating from any particular location. Fish eggs and larvae that are released during subsequent spawning events during the extended spawning period would not be exposed to the same conditions and risk of exposure to seismic emissions. Due to these factors impacts to fish eggs and larvae associated with the Otway Basin 3D MC MSS would be orders of magnitude smaller than regional scale environmental drivers that influence survival and recruitment of fish species to natural environments and into commercial fish stocks that are harvested by commercial fisheries operating in the area.

It is considered that the consequence of acoustic emissions on fish eggs and larvae within the OA (including for commercially important species retained as part of the CTS, SESSF, ETBF, and SBT (long-lining) fishery) is minor; with no detectable adverse effects on fish populations and rapid recovery from any impact is expected to occur. Based on available evidence, it is considered likely that fish egg and larvae mortality associated with exposure to acoustic emissions has occurred at very small scale during other similar seismic data acquisition projects. As such, the residual risk of fish egg and larvae mortality based on exposure to acoustic emissions associated with the Otway Basin 3D MC MSS has been assessed as **Low** (*Minor x Likely*) (**Table 49**).

7.2.2.2.3.3 Recoverable Injury

Exposure to seismic emissions have been reported to cause recoverable injuries to fish. These recoverable injuries have included fin hematomas and capillary dilation (*Popper et al.*, 2014). Temporary reduction in hearing sensitivity (i.e. TTS) due to fatigue and temporary changes to the epithelium (hair cells) of the inner ear and/or damage to auditory nerves innervating the ear (Worcester, 2006; *Popper et al.*, 2014) has the potential to occur in some fishes exposed to intense sound pressures for prolonged periods of time (Smith *et al*., 2006; Popper *et al*., 2014; Liberman, 2015).

TTS has been demonstrated in some fish species and is variable in duration and magnitude (Popper *et al*., 2014). This shift is temporary on account of fish sensory hair cells being constantly added (e.g. Popper and Hoxter, 1984; Lombarte and Popper, 1994) or replaced when damaged (Smith *et al*., 2006; Schuck and Smith, 2009). Following cessation of the damaging sound, normal hearing ability returns over a period that is variable, depending on many factors, including the intensity and duration of sound exposure (e.g. Scholik and Yan, 2001; Amoser and Ladich, 2003; Smith *et al*., 2011). In all cases where TTS occurred, it was only found after multiple exposures to intense sounds (e.g. <190 dB re 1 µPa rms) or as a result of long-term exposure (e.g. tens of minutes or hours) to somewhat less intense sounds (Popper and Hawkins, 2018). While experiencing TTS, affected fishes may have a decrease in fitness in terms of communication, detecting predators or prey, and/or assessing their environment (Popper *et al*., 2014; Popper and Hawkins, 2018).

The impact threshold of 186 dB re 1 µPa2·s proposed by Popper *et al.* (2014) is based on data from Popper *et al.* (2005) where exposure of a freshwater fish species with a connection between the swim bladder and inner ear to an SELcum of 186 dB re 1 µPa2·s resulted in approximately 20 dB difference in hearing threshold. Fish that showed TTS recovered to normal hearing levels within 18 – 24 hours.

Predicted onset distances for recoverable injuries and TTS in each of the three fish classifications derived by Popper *et al.* (2014) are provided in **Table 67.**

Table 67 Predicted onset distances (single pulse and SEL_{24h}) for recoverable injury and temporary threshold shift in fish (Groups I, II, and III), both within the water column and at the seafloor

	Recoverable injury		TTS	
	Per Pulse (peak)	SELcum	Per Pulse (peak)	SELcum
Group I: Fishes without a swim bladder that can sink and settle on the substrate when inactive				
Accepted sound exposure threshold	213 dB PK	216 dB SEL_{24}	-	186 dB SEL_{24}
Maximum modelled distance (horizontal) (water column) (m)	70	110	-	4,800
Maximum over seafloor modelled distance (seafloor) (m)	No exceedance predicted	No exceedance predicted	-	4,500
Group II: Fishes with swim bladders whose hearing does not directly involve the swim bladder or other gas volumes **Group III:** Fishes whose hearing does directly involve a swim bladder or other gas volume				
Accepted sound exposure threshold	207 dB PK	203 dB SEL_{24}	-	186 dB SEL_{24}
Maximum modelled distance (horizontal) (water column) (m)	140	110	-	4,800
Maximum over seafloor modelled distance (seafloor) (m)	No exceedance predicted	No exceedance predicted	-	4,500

The potential for TTS effects to occur as a result of cumulative sound exposures has been evaluated based on the accumulated sound energy over a 24-hour period for different locations within the OA and using the 186 dB re 1 µPa2·s threshold (Popper *et al*., 2014). The UAM (Welch *et al*. 2023) predicts that TTS at the seabed may occur up to 4.5 km from acquisition lines on the upper continental slope in water depths down to approximately 1,500 m, although this range reduces to 1.7 km in water depths of approximately 2,000 m. Although not modelled, the ranges to TTS in deeper waters are expected to reduce further. The maximum modelled distance is measured broadside of the acquisition lines, and the distance to impact for fishes located fore and aft of the approaching seismic vessel will be limited to shorter distances.

The SEL24h cumulative metric reflects the dosimetric impact of noise levels based on the assumption that an animal is consistently exposed to such noise levels at a fixed position during that 24-hour period. The radii that correspond to SEL24hr typically represent an unlikely worst-case scenario for SEL-based exposure since, more realistically, fishes would not stay in the same location or at the same range for 24-hours. Therefore, this method is highly conservative and a reported radius of SEL24hr criteria does not mean that any animal travelling within this radius of the source will suffer hearing impairment. As the Seismic Vessel is constantly moving along each sail line at an average speed of 4 – 5 knots, to exceed industry practice levels it would require a fish to actively follow the course of the vessel for a 24-hr period to be exposed to acoustic emissions that are considered capable of causing TSS.

An expert peer review undertaken by Popper and Hawkins (2019) in relation to the potential for TTS impacts to demersal fishes from a 3D MSS in Australia highlighted the reasons why the 24-hour period is conservative. Each individual fish is exposed to relatively "loud" sounds for only a short period of time and the exposure is only at levels that might lead to potential effects if the fish is relatively close to the sound source for an extended period. The modelled SEL24h scenarios are not weighted to the auditory thresholds of fishes and so account for many seismic pulses over the 24-hour period that are likely too low and distant for fishes to be able to hear (Popper and Hawkins, 2019). With regard to TTS, Popper and Hawkins (2019) concludes:

- TTS is not likely to occur as the signal will not be very much above threshold for the bulk of fishes since they have no hearing specialisations. In the event that there is TTS, the amount of TTS is likely to be limited;
- If TTS occurs, the duration of exposure to the most intense sounds that could result in TTS will be over just a few hours and its level is likely to be sufficiently low that it will not be possible to easily differential it from normal variations in hearing sensitivity;
- Even if fish do show some level of TTS, recovery will begin immediately following the cessation of the most intense sounds, and recovery is likely to occur, to a limited extent, between seismic pulses; and
- Based on very limited data, recovery within 24-hours (or less) is very likely.

As with the mortality and injury impact predictions, the modelled extent over which TTS has the potential to occur in fishes is likely to be highly conservative and the mobile demersal fishes are likely to move away from the approaching acoustic source before sound levels reach those that may result in significant levels of TTS. It is possible that some fishes may not avoid the approaching acoustic source completely and some level of TTS is possible, but as Popper and Hawkins (2019) summarises, recovery is likely to occur within 24-hours and the potential for such effects to have significant implications on the fishes' fitness and survival is low.

The 2D tie line that will extend into the continental shelf has not been modelled in the context of SEL24h exposures given that acquisition in shallower continental waters will be limited to a few hours of active source time (not a full 24-hour period) and the acoustic source will approach shallower waters in the endfire direction (associated with smaller sound propagation and effects ranges). Therefore, accumulated SEL exposures and the range to TTS effects along the 2D tie line on the continental shelf is expected to be localised and not exceed the ranges modelled for the slope region.

Following exposure to seismic emissions no significant changes in the diversity and abundance of fish species on various reef and non-reef habitats in western Australian waters have not been reported (Miller and Cripps, 2013, Meekan *et al*., 2021). These results indicate that even if fish experience TSS, the effect is not detectable at a population level within a short-, medium- and long-term following exposure (Meekan *et al*., 2021).

The presence of tuna in the Otway Basin supports a significant commercial fishery, particularly within South Australian waters (see **Section 4.7.3.2.5**). Song *et al.* (2006) reported on an examination of the inner ear of Atlantic bluefin tuna (*Thunnus thynnus*) and report that the inner ears were structurally adapted to protect the ear during high-speed acceleration and during dives to great depths. Song *et al.* (2006) concluded that the studied species does not have particularly good hearing and that in order for sound to be detected by tuna, it would have to be very loud. Therefore, fish would have to be close to even the loudest anthropogenic sources in order for detection to take place (Song *et al*., 2006). Furthermore, Song *et al*. (2006) stated that "*unless bluefin tuna are exposed to very high intensity sounds from which they cannot swim away, short - and long-term effects may be minimal or non-existent. And, considering that bluefin tuna are powerful swimmers and divers, it is possible that if they encounter a sound that is very loud to them, they will move away from the sound rapidly enough to result in minimal exposure. At the same time, if the tuna are, for some reason, unable to move away from very intense sounds, there is still the possibility that there could be damage to the inner ears*". Furthermore, Popper *et al*. (2013) and Dale *et al*. (2015) reported that the hearing range of Pacific bluefin tuna (*Thunnus orientalis*) is narrower than for other fishes that do not have specializations for sound detection and therefore have poorer hearing abilities than other fishes. Based on the findings of Song *et al*. (2006), Popper *et al.* (2013), and Dale *et al.* (2015) on closely related tuna species (i.e. of the genus *Thunnus*), it is assumed that SBT also have low hearing abilities and are unlikely to suffer TTS from acoustic emissions during the Otway Basin 3D MC MSS.

It is considered that based on the results of the UAM (Welch *et al*., 2023), the fast recovery speeds and the implausibility of how cumulative exposure resulting in TTS that the consequence of acoustic emissions resulting in recoverable injury for fishes, both site attached and pelagic (including commercially important species retained as part of the CTS, SESSF, ETBF, and SBT (long-lining) fishery) is considered to be minor; with no detectable adverse effects on fish populations and rapid recovery from any impact is expected to occur. As stated in Halvorsen *et al.* (2013), although TTS can arise from prolonged exposure to sound, it is not likely to be of great significance for fishes that are only briefly exposed to a source. Based on available evidence, it is considered that recoverable injuries to fish associated with exposure to acoustic emissions may occur in exceptional circumstances. As such, the residual risk of recoverable and TTS injury to fish due to exposure to acoustic emissions associated with the Otway Basin 3D MC MSS has been assessed as **Low** (*Minor x Rare*).

7.2.2.2.4 Elasmobranchs

Very little research has been undertaken on the effects of acoustic noise or MSSs on elasmobranchs. Sharks differ to bony fish in that they have no swim bladder or other gas filled chambers that can act as secondary hearing organs in the body, so are unlikely to respond to changes in pressure like bony fish may be due to the physiological differences (Myrberg, 2001; Casper *et al*., 2012). As a result, sharks cannot detect pressure changes associated with sound waves (Carrol *et al*., 2017). The lateral line system of shark also does not respond to normal acoustic stimulus and is not able to detect sound-induced water displacements beyond a few body lengths, even with large sound intensities (Myrberg, 2001). There have been reports of sharks approaching and biting active acoustic source in both New Zealand and Australia while sharks including blue sharks and mako sharks have been sighted close to seismic vessels while the source is active. These interactions may be influenced by changes to electromagnetic field associated with the use of data acquisition equipment.

No sound exposure thresholds currently exist for acoustic impacts from seismic sources to sharks and rays, which are sensitive only to particle motion. However, as a conservative approach the Popper *et al.* (2014) guidelines for fish with no swim bladder have been used for this assessment (**Table 66**). The maximum Rmax distances predicted by the UAM (Welch *et al*., 2023) for recoverable injury, potential mortal injury or mortality in Group I fishes (no swim bladder) within the water column is 70 m. The maximum predicted distance to TTS is 4.8 km within the water column, based on the cumulative SEL24h threshold. However, given the free-swimming and highly vagrant nature of sharks, as well as their lack of sensitivity to sound pressure, injury and significant levels of TTS are not expected to occur.

The elasmobranch species potentially present within the AA will be limited to a narrow margin on the upper continental shelf and slope within the northern and eastern extents of the AA and so only subject to exposure if a limited number of seismic lines are acquired along these narrow margins or within the 2D Tie Line AA. White sharks are an exception to this with their known distribution extending across both shelf and oceanic areas. Shark species are highly vagrant and naturally cover large distances, and as such, short-term exposures from the transient acoustic source is expected to result in only localised behavioural responses and movements of sharks (**Section 7.2.2.3.3**).

It is considered that based on the available evidence that the consequence of acoustic emissions on elasmobranchs is minor; with no detectable adverse effects on populations and rapid recovery from any impact is expected to occur. Based on available evidence, it is considered that physiological effects to elasmobranchs associated with exposure to seismic emissions may occur in exceptional circumstances. As such, the residual risk of physiological impacts to elasmobranchs due to acoustic emissions associated with the Otway Basin 3D MC MSS has been assessed as **Low** (*Minor x Rare*) and considered to be acceptable (**Table 49**).

7.2.2.2.5 Cephalopods

As described in **Section 4.5.4**, there are 17 species of cephalopod (including various species of squid, octopus, and cuttlefish) that may be present within the OA, none of which are listed as EPBC threatened fauna. Given their pelagic lifestyle, where they spend the daytime near the seabed and then rise to the surface waters to feed at night, there is the potential for squid and cuttlefish to come near the acoustic source during the Otway Basin 3D MC MSS. Octopus, on the other hand, are primarily reef dwelling benthic species so are less likely to be encountered in concentrations of significance in the OA.

Cephalopods have been found to respond to sound between 30 and 600 Hz, being most sensitive between 100 and 200 Hz, suggesting that they detect sound similarly to most fish, with the statocyst acting as an accelerometer through which they detect the particle motion component of a sound field (Kaifu *et al.*, 2008; Mooney *et al*., 2010).

Acoustic trauma has been observed in captive cephalopods. Laboratory studies that exposed two species of squid to seismic noise showed that *Alloteuthis sublata* was tolerant to a sound level up to 260 dB, yet *Loglio vulgaris* was fatally injured at levels of 246 – 252 re 1 µPa within 3 – 11 minutes of exposure (Norris and Mohl, 1983). Andre *et al*. (2011) exposed four cephalopod species (two squid, one octopus and one cuttlefish species) to low frequency sounds with SELs of 157 ± 5 dB re 1 µPa (peak levels at 175 re 1 µPa). All exposed animals exhibited changes to the sensory hair cells (statocysts) responsible for balance, with damage becoming more pronounced in animals continuously exposed for up to 96 hours. This study estimated that trauma effects could occur out to 1.5 – 2 km from an operating acoustic source (Andre *et al*., 2011). However, the exposure experiments in both studies are difficult to relate to real life MSSs due to either the exposure levels or the duration of the exposure event.

Fewtrell (2003) found that southern calamari squid (*Sepioteuthis australis*) were able to detect acoustic noise at approximately 158 dB re 1 µ Pa, or at 2.1 km from a 2,678 in^3 acoustic source, although no trauma examination was conducted. However, Fewtrell (2003) did conclude that MSS noise of up to 192.4 dB re 1 µ Pa (0.2 km from a 2,678 in^3 acoustic source) is not lethal for *S. australis*.

Carroll *et al*. (2017) undertook a literature review on the physiological and physical effects of MSSs on fish and invertebrates, including cephalopods (**Table 68**). Studies were categorised into presence or absence of a response depending on the level of exposure. The level of exposure was determined to be either "*realistic*" for MSSs (i.e. few short bursts of low frequency sound at >1 – 2 m), or "*unrealistic/unknown*" (i.e. continuous sound exposure, >100 bursts of near-field sound exposure in aquaria). The authors found no studies that had used "*realistic*" exposure levels and five that had used "*unrealistic/unknown"* exposure levels, including the Andre *et al*. (2011) study described above. Three had found damage to the statocyst (i.e. Andre *et al*., 2011, Solé *et al*., 2013a; 2013b), one found respiratory suppression (i.e. Kaifu *et al*., 2007), and another found wider ecosystem consequences/stress bio-indicators (i.e. Solan *et al*., 2016).

Table 68 A Summary of the Potential Impacts of Low Frequency Sound on Cephalopods

Effect	Cephalopod
Physical	
Otolith/statocyst damage	3
Organ/tissue damage	1
Mortality/abnormality	1
Physiological	
Metabolic rates*	1
Stress bio-indicators	1
Immune response	
Energy stores	
Behavioural	
Startle response	5
Sound avoidance	1
Predator avoidance	
Foraging	
Reproduction	
Bioturbation	
Key	
(green)	No response at either realistic or unrealistic exposure levels
(red)	Response at realistic exposure levels
(yellow)	Response at unrealistic/unknown exposure levels
(blue)	Possible response (conflicting results)
(grey)	No data, has not been tested

Notes: *Includes proxies for metabolic rate such as food consumption, growth, respiration, developmental rate.
Numbers represent the number of studies reporting the result (as reported by Carroll *et al*., 2017).
Impacts are classified according to the sound exposure treatments as realistic (i.e. short bursts of low-frequency sound at a distance of >1 – 2 m) or unknown/unrealistic (i.e. long duration and/or short distance of <2 m to sound source, nearfield sound exposure in aquaria).
Source: Table adapted from Carroll *et al.*, (2017)

Squid are generally short-lived, fast growing species with high fecundity rates and studies have shown that squid can produce eggs year-round. So, if there was any potential for loss in recruitment over a three-month period, then the squid's life history traits mean they are well adapted to disturbance and the populations would not be at the same risk as those species which only spawn once a year.

Given the ability of cephalopods to move and avoid exposure to some degree and the behavioural responses in studies, exposure to injurious levels is unlikely. This, combined with the finding that a relatively high SEL, was found to be non-fatal to squid, and that larvae and juveniles are most often found in shallow coastal waters, suggests that there is no anticipated long-term risk to squid populations presented by the Otway Basin 3D MC MSS. There is no evidence to suggest that other cephalopod species are more prone to physiological impacts from underwater noise than squid, consequently, the residual risk to cephalopod physiology arising from acoustic emissions during the Otway Basin 3D MC MSS has been assessed as **Low** (*Minor* x *Unlikely*).

7.2.2.2.6 Marine Reptiles

As described in **Section 4.5.5**, there are three species of threatened marine turtle that are known, likely, or may be present in the OA. Only leatherback turtles typically have a temperate distribution and are regularly seen in TAS and VIC waters during the summer months, although sightings are mainly of foraging individuals in coastal and continental shelf waters, not deep offshore waters such as those of the OA.

Marine turtles do not have an external ear but detect sound through bone-conducted vibration in the skill, and by using their shell as a receiving surface (Lenhardt *et al*., 1985). Nelms *et al*. (2016) conducted a thorough literature review of studies that investigate the behavioural and physical impacts of seismic surveys on turtles. Nelms *et al*. (2016) reported that for those marine turtle species for which hearing sensitivities are known (loggerhead, green, leatherback and Kemp's ridley turtles – of which all but Kemp's ridley turtles have a potential presence in the OA), all can detect frequencies between 50 and 1600 Hz, and that this range overlaps with the peak amplitude low frequency sound produced during seismic surveys (10 – 500 Hz). This suggests that turtle hearing will detect seismic operations, although hearing sensitivity is relatively poor compared to marine mammals (Finneran *et al*., 2017) and no studies have assessed physical (tissue) damage to hearing structures. One study (Gurjao *et al.*, 2005), looked for evidence of turtle mortality during 2D seismic surveys off the coast of Brazil. Of the eight dead turtles found in the vicinity, five appeared to have been recently caught and damaged by fishing activity and had subsequently died. The authors do not speculate as to the cause of death for the other three dead turtles, and it is unclear whether any post-mortems were conducted on these individuals.

TTS has been induced in captive playback experiments where loggerhead turtles were exposed to a few hundred seismic pulses at a distance of 65 m (Moein *et al.,* 1994, cited in National Science Foundation, 2011). Although this demonstrates that hearing damage is theoretically possible, the results of captive experiments are of questionable relevance when assessing effects of seismic surveys in an open ocean setting as unlike wild animals, captive animals are unable to move away from the sound source. Instead, the impact of underwater noise on marine turtles is likely to be influenced by the exposure duration, where acute noise from seismic surveys is most likely associated with behavioural effects (see **Section 7.2.2.3.5**) rather than physiological effects (Commonwealth of Australia, 2017a). Physiological effects for marine turtles are probably limited to situations when animals might be exposed at close range for unusually long periods (National Science Foundation, 2011), such situations are unlikely during the Otway Basin 3D MC MSS as the vessel will be moving continuously along pre-determined sail lines; hence exposure to high levels of underwater noise will be transitory for any turtles in the OA.

The underwater noise exposure criteria for physiological effects on marine turtles are presented in **Table 69**. The criteria are based on the recommendations of the US Navy (Finneran *et al*., 2017) which, on account of there being no published data regarding TTS and PTS in marine turtles from impulsive noise sources, base threshold values on extrapolations from other animal groups. UAM results for the Otway Basin 3D MC MSS do not predict PTS or TTS for marine turtles from exposure to a single pulse, but PTS could occur if a turtle was to remain within 110 m of the active source for 24-hours or TTS is possible for turtles that remain within 310 m of the active source for 24-hours. Noting that the likelihood of cumulative exposure is dramatically reduced on account of the movement of the Seismic Vessel, where at a speed of 4.5 knots the Seismic Vessel will travel up to 200 km in 24 hours, and the ability for turtles to spend time with their heads above the water surface to avoid exposure.

Table 69 Noise Exposure Criteria (Finneran *et al.,* 2017) and Modelled Zones of Impact (Maximum Distances from Source to Impact Threshold) for PTS and TTS in Marine Turtles

	PTS		TTS	
	Criteria	Maximum Threshold Distance (m)	Criteria	Maximum Threshold Distance (m)
Single pulse PK	232 L_{pk}; dB re 1 µPa	-	226 L_{pk}; dB re 1 µPa	-
Cumulative Weighted SEL_{24hr}	204 $L_{E,24h}$; dB re 1 µPa²·s	110	189 $L_{E,24h}$; dB re 1µPa²·s	310

Notes: A dash indicates the threshold is not reached within the limits of the modelling resolution (20 m).

Acute noise from seismic surveys is considered in the Recovery Plan for Marine Turtles in Australia 2017 – 2027 (Commonwealth of Australia, 2017a). This report acknowledges that loggerhead turtles are known to be sensitive to sounds of between 100 – 400 Hz, and that green, leatherback and hawksbill turtles can detect frequencies up to 1600 Hz, but despite this very little is known of the impact of noise on marine turtles. The report also states that "*Given that the impacts of noise are unknown, a precautionary approach should be applied to seismic work, such that surveys planned to occur inside important inter-nesting habitat should be scheduled outside the nesting season*."

As identified in **Section 4.5.5**, there are no areas for marine turtles within either the OA or EMBA that have been identified as BIAs for any stage (e.g. breeding, nesting, feeding, etc), therefore the OA is not considered to be important habitat and although some marine turtles may be present within the OA, they are not expected to be present in high numbers. The UAM (Welch *et al.,* 2023) modelling predicts that 24-hour cumulative TTS effects for marine turtles could occur out to 310 m from the active source and the zone of impact for 24-hour cumulative PTS is restricted to 110 m around the active source; hence, the risk of PTS or TTS for individual marine turtles is very low, and no anticipated population level effects are predicted. Individual turtles could occur within the highly restricted zone (<20 m) in which PTS or TTS from single pulse exposure is expected; however, individual turtles would presumably be displaced from this area by the hull of the Seismic Vessel (which precedes the acoustic source). Furthermore, a 100 m precautionary Shut-down Zone from the operating source will be applied to marine turtles. The acoustic source will be shut-down, or start-up will be delayed for 15 minutes if a marine turtle is observed within the 100 m Shut-down Zone. Operation of the acoustic source using soft-starts may only resume when the turtle has been observed to move outside the 100 m Shut-down Zone, or when 15 minutes have lapsed since the last turtle sighting.

Consequently, the residual risk to marine turtle physiology arising from acoustic disturbance during the Otway Basin 3D MC MSS has been assessed as **Negligible** (*Negligible* x *Rare*).

7.2.2.2.7 Marine Mammals

Marine mammals are dependent on sound for their survival. They use sound during foraging, reproduction, communication, detection of threats, and navigation, and as a result, are particularly sensitive to anthropogenic noise (Weilgart, 2007; Williams *et al*., 2015; Erbe *et al*., 2018). Both lethal and sub-lethal physiological effects are possible when marine mammals are exposed to high intensity underwater noises at close range. Potential effects include damage to body tissues (resembling decompression sickness in humans), damage to hearing, and chronic stress (Gordon *et al*., 2003). Amplitudes that would result in such effects are unknown for most species, but onset thresholds have been developed for some captive species to predict physiological effects, and these thresholds have been extrapolated for all marine mammals (Southall *et al*., 2019). All thresholds for permanent hearing injury are inferred for ethical reasons (Southall *et al*., 2019).

Shipping noise is highly unlikely to cause permanent hearing damage to marine mammals (Southall and Hatch, 2008); however, long-term exposure may induce a stress response similar to that found in humans that live near busy roads or airports (Wright *et al*., 2007). Chronic stress in response to vessel noise was first hypothesised by Rolland *et al.* (2012) for North Atlantic right whales. These authors reported that following a significant reduction in background noise levels in the Bay of Fundy, California following the events of September 11, 2001, baseline levels of stress-related faecal hormone metabolites in right whales decreased significantly. Lemos *et al.* (2022) have recently documented a similar response in gray whales off the west coast of the US. It is well recognised that chronic stress can supress the immune system, compromising the health of an animal (Weilgart, 2013). Increases in stress hormones have been observed in captive beluga whales and bottlenose dolphins exposed to sound emissions from an acoustic source (Romano *et al*., 2004; Yang *et al*., 2021).

While tissue damage from explosives shock waves has been demonstrated for marine mammals (Finneran and Jenkins, 2012; Koschinski and Kock, 2009) pressure changes from acoustic sources associated with seismic surveys have longer rise times and are less likely to cause tissue damage than explosives. To date there is no definitive evidence of acute physical damage or mortality to marine mammals from seismic surveys (Gordon *et al*., 2003; Broker, 2019); however, Gray and van Waerebeek (2011) reported a single pantropical spotted dolphin showing severe behavioural distress followed by ataxia near a seismic array. Mann *et al*. (2010) reported several incidences of permanent hearing loss in stranded odontocetes for which exposure to high levels of anthropogenic noise cannot be dismissed.

Exposure to high intensity noises can result in a 'threshold shift'; that is a change in the ability of an animal to hear, usually at a certain frequency, whereby sensitivity to one of more frequencies is lost (Southall *et al*., 2007; Southall *et al*., 2019). Threshold shifts can be temporary (i.e. TTS), with recovery after minutes or hours, or be permanent (i.e. PTS). Threshold shifts in marine mammals are more commonly temporary on account of their mobile, free-ranging nature which means they are usually able to avoid dangerously high SELs that could cause PTS. However, exposure to sounds that cause TTS can potentially cause PTS if an animal is repeatedly exposed over a sustained period (Kastelein *et al*., 2016). To cause immediate PTS to marine mammals, levels of acoustic exposure would need to be very high (Richardson *et al*., 1995; Southall *et al*., 2019).

Many factors influence the magnitude of any TTS effect, including the species impacted, the sound frequency, bandwidth, amplitude, exposure duration, recovery period, and whether the noise is continuous or intermittent (Popov *et al.,* 2013). Most TTS studies to date have been conducted on odontocetes as these are the species typically held in captivity on which controlled exposure experiments can occur (e.g. Finneran *et al*., 2015). No TTS studies to date have been conducted on baleen whales; hence, all estimates of TTS onset thresholds for these species are based on extrapolation from species for which data does exist (Southall *et al*., 2019).

The duration of TTS recovery depends on the magnitude of the TTS (i.e. how much hearing sensitivity has changed). For example, bottlenose dolphins exposed to 30 minutes of continuous 160 dB re.1µPa tonal noise exhibited a TTS of 8 dB five minutes after exposure, and full recovery occurred within an hour (Nachtigall *et al*., 2004), whereas dolphins exposed to continuous tonal noise of 186-194 dB re.1µPa exhibited a TTS of 45 dB with almost no recovery in the first hour post-exposure and complete recovery requiring up to four days (Finneran *et al*., 2007). Comparisons between intermittent and continuous sound exposures have been made and reveal that intermittent exposure resulted in a lower TTS than continuous exposure indicating a partial recovery during the pauses of intermittent exposure (Finneran *et al.*, 2010). This is of high relevance to seismic surveys which use intermittent or impulsive noise during operations.

Finneran *et al*. (2015) measured TTS in bottlenose dolphins exposed to impulsive acoustic sources and found much lower magnitude threshold shifts than those caused by continuous tones. In this study a 150 cubic inch (2,000 PSI) acoustic source at a range of c. 4 m to the subject dolphins exposed the animals to SPLs of 200 – 212 dB re.1µPa; however, the maximum TTS recorded was only 9 dB. This study also documented an intriguing anticipatory behaviour whereby two of the three individual dolphins tested independently learnt to turn their heads away from the noise just before each impulse was generated, by doing so, these animals could 'self-mitigate' against exposure. While Finneran *et al*. (2015) did not comment on TTS recovery duration, given the relatively low TTS responses observed, the recovery durations would nearly certainly be short (i.e. less than one hour: cf. Nachtigall *et al*., 2004). Most TTS studies on marine mammals to date document full recovery within 24 hours of exposure (NMFS, 2018). Popov *et al*. (2013) demonstrated that regardless of frequency, an increase in exposure duration resulted in increases to both the magnitude of the TTS and the time to recovery. It is noteworthy that individuals of the same species exposed to the exact same noise under identical experimental conditions can exhibit considerably different TTS responses, indicating significant inter-individual variability in susceptibility to hearing impairment (Popov *et al*., 2013).

Establishing the distance at which threshold shifts are predicted to occur from a given sound source in the marine environment is facilitated by UAM and is dependent on the characteristics of the acoustic source (i.e. frequency, sound speed profile within the water column, seabed composition, water depth and exposure duration: David, 2011). For intermittent noise exposures in the marine environment, cumulative SEL, defined as the total SEL calculated over the time the noise source is active, is often used to characterise exposure (Finneran, 2015). The cumulative SEL considers the received level of sound and the duration of exposure (NMFS, 2018), typically over a 24-hour period, for anthropogenic underwater noise.

To assess the effects of underwater noise on marine mammal auditory function, marine mammals are characterised by 'hearing groups' (**Table 70**) based on their functional hearing range (Southall *et al*., 2019). The low-frequency (**LF**) cetaceans are defined as the baleen whales. These species can hear sound within a frequency range of a few Hz to a few tens of kHz, which coincides with the frequency range of impulsive seismic signals. Odontocetes are considered to have their peak hearing sensitivity at frequencies greater than this, they are grouped as either high-frequency (**HF**) or very high-frequency cetaceans (**VHF**). These species are less sensitive to the low frequency seismic signals, although some of the sound produced is still audible to them. For each hearing group thresholds for the onset of TTS and PTS in marine mammals were determined by Southall *et al*. (2019) and are presented in **Table 70.**

UAM was undertaken by Welch *et al.* (2023) for the purpose of quantifying the potential effects on marine mammals of underwater survey noise (as described in **Section 7.2.1.2**). The predicted zones of impact from a single pulse of the acoustic source are presented alongside the predicted zones of cumulative impact over a 24-hour period (during which c. 12,000 – 14,000 pulses would occur) in **Table 70**. For this EP, both the single pulse and the cumulative modelling results are used to assess the potential zones of impact on marine mammals; however, the larger threshold distance generated by the cumulative results is generally regarded as being of greatest relevance when assessing ecological impacts. In reality, both scenarios are imperfect as the length of time that free-ranging wild animals would spend near the active source would inevitably be longer than a single pulse, but shorter than the 24-hour cumulative metric. Additional animal movement modelling has been undertaken for PBW and SRW to more realistically represent the time that they might be present around the Seismic Vessel on account of the relative proximity of the OA to the blue whale Foraging BIA and the SRW Aggregation BIA.

Whales, as defined by Policy Statement 2.1 include baleen whales and larger toothed whales (e.g. sperm whales, killer whales, false killer whales, pilot whales and beaked whales). For the purpose of interpreting the UAM results it is important to note that baleen whales are LF cetaceans, while the larger toothed whales are typically HF cetaceans. The only VHF cetacean species with a potential presence in the OA are the pygmy sperm whale and dwarf sperm whale and the spectacled porpoise.

Table 70 PTS and TTS Onset Thresholds for Marine Mammals Exposed to Impulsive Noise (Southall *et al.*, 2019) and Maximum Predicted Zones of Impact (Maximum Horizontal Distances) from Source to Onset Threshold.

Hearing group	PTS and TTS onset thresholds – impulsive noise events							
	PTS onset				TTS onset			
	Single pulse PK		Cumulative Weighted SEL24hr		Single pulse PK		Cumulative Weighted SEL24hr	
	PK (dB re 1µPa)	Maximum predicted distance (m)	Weighted SEL24hr (dB re 1µPa2.s)	Maximum predicted distance (m)	PK (dB re 1µPa)	Maximum predicted distance (m)	Weighted SEL24hr (dB re 1µPa2.s)	Maximum predicted distance (m)
Low frequency (LF) cetaceans	219	-	183	500	213	70	168	156,000
High-frequency (HF) cetaceans	230	-	185	-	224	-	170	100
Very-high-frequency (VHF) cetaceans	202	360	155	110	196	680	140	850
Otariid seals	232	-	203	-	226	-	188	100

Note: LF cetaceans = all baleen whales,
HF cetaceans = most dolphins, beaked whales, sperm whales and killer whales
VHF cetaceans = true porpoises, most river dolphins, pygmy/dwarf sperm whales, *Cephalorhynchus spp*, hourglass and Peale's dolphins.
A dash indicates that the threshold is not reached within the limits of the modelling resolution (20 m)

In addition to acoustic propagation modelling results (i.e. UAM, as presented in **Table 70**), animal movement modelling ('Animat' modelling) was also undertaken using movement simulations for PBWs and SRWs, being the cetacean species for which biologically important habitat occurs in the vicinity of the OA. This modelling allowed estimations of the distance within which 95% of the TTS and PTS threshold exceedances would occur ($ER_{95\%}$), along with the probability that individuals within that distance would be exposed above the relevant threshold (P_{exp}). Exposure ranges from animat modelling for PTS and TTS thresholds are typically shorter than those predicted using acoustic propagation modelling because of the shorter dwell time of moving animals which represents a more realistic approach for free-ranging pelagic marine mammals.

Pygmy Blue Whale Animat Results

The results of the animat modelling for PBWs are presented in **Table 71**. The animat scenarios modelled for PBWs were:

- Scenario 1a – Unrestricted animat movements to ascertain exposure ranges to animats in all directions from the survey lines (with maximum exposure ranges associated with offshore, downslope propagation); and
- Scenario 1b – Animat movements restricted to the continental shelf to ascertain exposure ranges inshore towards the continental shelf.

In all scenarios PTS and TTS exposure ranges were substantially less than those estimated by UAM (**Table 70**). Based on the animat results, potential for PTS effects is limited to within 130 m of the seismic source. $ER_{95\%}$ ranges to TTS in the offshore downslope direction are approximately 27.9 – 31.7 km and in the inshore, upslope direction, the ranges to TTS are approximately 15.3 – 15.4 km. The probability of exposure within $ER_{95\%}$ varied between 32 and 53%, indicating that some, but not all, animats exposed within the 95th percentile range were exposed above threshold. This is because simulated whales can move in and out of the modelling range and change their vertical position in the water column. Hence the length of time they are within the exposure radius is moderated by their movements. For example, a whale within the predicted exposure range that is traveling quickly will not accumulate as much exposure as a whale that is travelling slower. Likewise, individual whales may spend more time at depths with quieter sound levels.

Table 71 Animat Modelling Results for the Two Different Scenarios relative to Pygmy Blue Whales

Threshold		Scenario 1a				Scenario 1b			
		Female		Male		Female		Male	
	dB	$ER_{95\%}$ (m)	P_{exp} (%)	$ER_{95\%}$ (m)	P_{exp} (%)	$ER_{95\%}$ (m)	P_{exp} (%)	$ER_{95\%}$ (m)	P_{exp} (%)
PTS (SEL_{24hr})	183	120	52	130	53	-	-	-	-
TTS (SEL_{24hr})	168	31,700	46	27,900	50	15,400	32	15,300	33

Dashes indicate no simulated whales were exposed above threshold.

Southern Right Whale Animat Results

The results of the animat modelling for SRWs are presented in **Table 72**. The animat scenarios modelled for SRWs were:

- Scenario 2a – Animat movements restricted to the known core range area to ascertain exposure ranges to animats on the continental shelf inshore from the survey lines; and
- Scenario 2b – Animat movements restricted to the continental shelf to ascertain exposure ranges to animats on the continental shelf inshore from (and including) the survey lines.

Both scenarios provide an indication of the potential zone of effects from seismic acquisition offshore towards sensitive migration, resting, aggregation, calving and breeding habitats (BIAs) in continental shelf waters.

Table 72 Animat Modelling Results for the Two Different Scenarios relative to Southern Right Whales

Threshold		Scenario 2a				Scenario 2b			
		Mother & Calf		No Calf		Mother & Calf		No Calf	
	dB	$ER_{95\%}$ (m)	P_{exp} (%)	$ER_{95\%}$ (m)	P_{exp} (%)	$ER_{95\%}$ (m)	P_{exp} (%)	$ER_{95\%}$ (m)	P_{exp} (%)
PTS (SEL_{24hr})	183	-	-	-	-	40	98	40	97
TTS (SEL_{24hr})	168	-	-	8,510	33	10,800	61	11,000	67

Dashes indicate no simulated whales were exposed above threshold.

Based on the animat results, potential for PTS effects is limited to within 40 m of the seismic source. $ER_{95\%}$ ranges to TTS inshore of the survey lines is not predicted to occur (Scenario 2a), although when accounting for animals moving within the survey lines (Scenario 2b), the $ER_{95\%}$ range to TTS is 11 km. Based on these results, it can confidently be predicted that TTS effects will not extend from the OA to the Aggregation BIA (which occurs 14 km north of the OA) or any of the connecting habitat, migration and resting on migration BIAs in coastal waters.

Little is known about the movement of SRWs between aggregation areas and in offshore waters. The Conservation Management Plan for the Southern Right Whale 2011 – 2021 states that as migratory movements to and from calving grounds remain unknown, whales may be exposed to noise interference from seismic surveys during these movements (CoA, 2012). There remains the potential for TTS effects in SRWs offshore as they approach or disperse from shelf waters, however, given that these animals will be migrating/transient and some level of behavioural avoidance is likely, the potential for this to occur is limited.

Summary of modelling results relevant to physiological thresholds for marine mammals

The key results for physiological effects as predicted from both the UAM and the animat modelling can be summarised as follows:

- The UAM predicts that if baleen whales are present within 500 m of the active source over a 24-hour period they could experience PTS due to cumulative exposure. The animat modelling results, however, predict that the onset distance for cumulative PTS reduces to a maximum of approximately 130 m for PBWs and 40 m for SRWs when animal movement is accounted for;
- Temporary hearing damage (i.e. a TTS) is predicted by the UAM results for baleen whales should they remain within a 156 km radius of the active source for 24 hours. However, the animat modelling results predict that the maximum onset distance for 24-hour cumulative TTS for PBWs is approximately 32 km, and for SRWs is approximately 11 km;
- Exceedance of the onset threshold for PTS in high-frequency cetaceans is not predicted within the resolution limits of the acoustic propagation model. This means that even if high-frequency cetaceans are within 20 m of the active source for extended periods, no permanent hearing damage is expected. A TTS could occur if high-frequency cetaceans are within 100 m of the active source for 24-hours. However, the likelihood of this occurring is virtually nil as free-ranging pelagic animals would only be expected to remain in proximity of the active source for a short time (minutes) even if they were curious enough to investigate the towed seismic equipment at close range;

- Very-high-frequency cetaceans within 110 m of the active source could suffer cumulative PTS over a 24-hour period and TTS could occur due to cumulative exposure if very high-frequency cetaceans remain within 850 m of the active source for 24-hours. However, the UAM results suggested that exposure to a single pulse could elicit PTS beyond the predicted cumulative distance, with PTS out to 360 m. Because of this discrepancy the EP has assessed the effects of underwater noise of these species using the maximum onset distances of 360 m and 850 m respectively for PTS and TTS; and
- Exceedance of the onset threshold for PTS in otariid pinnipeds is not predicted within the resolution limits of the acoustic propagation model. This means that even if fur seals or sea lions are within 20 m of the active source for extended periods, no permanent hearing damage is expected. A TTS could occur if any individuals are within 100 m of the active source for 24-hours. However, the likelihood of this occurring is virtually nil as free-ranging pelagic animals would only be expected to remain in proximity of the active source for a short time (minutes) even if they were curious enough to investigate the towed seismic equipment at close range. In addition, seals are also able to avoid loud underwater noise by swimming with their heads above water when necessary (Mikkelsen *et al*., 2017). On this basis, no specific controls are warranted or proposed to protect pinnipeds from physiological effects of underwater noise.

General Controls to Address Potential Physiological Effects

All Australian marine mammals are fully protected under the EPBC Act, so the potential for causing physiological damage during any MSS is taken extremely seriously. This is particularly important for those species that have a threat classification; of which the following have been identified as having a 'known or likely' presence in the OA during the Otway Basin 3D MC MSS (see **Table 25**): blue whales (*endangered*), southern right whales (*endangered*), fin whales (*vulnerable*), and sei whales (*vulnerable*).

Based on the modelling results for cumulative TTS and PTS onset distances, the standard Shut-down Zones recommended in Policy Statement 2.1[16] are insufficient to manage the risk of auditory impairment to baleen whales during the Otway Basin 3D MC MSS. This coupled with the high likelihood of encountering PBWs in and around the blue whale foraging BIA for most months of the year (see **Table 26**) and the close proximity of the OA to the SRW Aggregation BIA, mean that additional management procedures are necessary to address the risk that the Otway Basin 3D MC MSS poses to baleen whales. The proposed control measures that will be implemented to protect marine mammals from physiological effects are discussed below, and are collated in **Appendix M**.

Animat modelling was undertaken to better understand the risk that the Otway Basin 3D MC MSS poses to PBWs and SRWs. This modelling incorporated species-specific ecological parameters to understand how animal movement (vertically and horizontally) will affect risk of exposure to these species during relevant life stages. Animat modelling therefore provides exposure ranges that are significantly more realistic than those produced by UAM; hence Animat modelling results have been used to underpin the control measures for these species in an effort to avoid potential physiological effects as outlined for PBWs and SRWs presently. In addition to the species-specific controls, the general Management Procedures (**MP**) listed below will be implemented and will afford protection to all marine mammal species. In addition, while standard management procedures outlined in Policy Statement 2.1 will be adopted for the Otway Basin 3D MC MSS, TGS has adapted some of these measures to provide increased protection to marine mammals. These are marked with an 'AC' superscript to denote an 'additional control'.

[16] A 3+ km observation zone, a 2 km low power zone and a 500 m shutdown zone.

- MP 1: During daylight hours at least one marine fauna observer (**MFO**) will be on duty at all times from the Seismic Vessel and one MFO will be on duty at all times from the Attending Support Vessel[17] to undertake continuous visual observations for marine mammals[AC].
- MP 2: MFOs will implement a 5+ km Observation Zone[AC] from the acoustic source[18]. In practise this means that MFOs will be required to scan as far as possible towards the horizon given the prevailing sightings conditions. In those circumstances when monitoring of the Observation Zone is a pre-requisite to certain operations (see **AMP 1**), the minimum radius permissible will be 5 km. Note that the implementation of this Observation Zone does not prohibit Low Visibility or Night-time Operations (see **MP 9**) but whenever conditions allow, this zone will be monitored.
- MP 3: During daylight hours, Pre Start-up Visual Observations for the presence of whales within the 5+ km Observation Zone will be undertaken for at least 30 minutes before the commencement of the Soft Start Procedure.
- MP 4: If no whales have been sighted within the relevant Shut-down Zones, Soft Start Procedures will commence over a 30-minute period.
- MP 5: A 2 km Shut-down Zone[AC] for all whales will be implemented throughout the entire OA at all times[19]. On this basis a Low Power Zone is unnecessary.
- MP 6: A Start-up Delay will occur if a whale enters or is detected in any relevant Shut-down Zone during the soft start. Whale presence within the Shut-down Zone will trigger an immediate and complete shut-down. Soft Start Procedures may only resume after the whale has been observed to move outside the Shut-down Zone, or when 30 minutes have lapsed since the last whale sighting.
- MP 7: If a whale is detected within any nominated Observation Zone during the Otway Basin 3D MC MS, an additional MFO will be stationed on the bridge of the vessel from which the detection was made to assist with observations. The only permissible exception to this is when the off-duty MFO is on a meal or toilet break or is standing-down having reached maximum shift duration for that particular working day. In these instances, a trained crew member will assist with marine mammal observations.
- MP 8: Stop Work Procedures will be implemented for the entire duration in which operations are underway as follows: the acoustic source will shut-down immediately whenever a whale is detected in, or about to enter, any relevant Shut-down Zone. Soft Start Procedures may only resume after the whale has been observed to move outside the Shut-down Zone, or when 30 minutes have lapsed since the last whale sighting.
- MP 9: Low Visibility[20] or Night-time[21] Operations may occur provided that there have not been three or more whale instigated shut-down situations during the preceding 24-hour period[22].
- MP 10: When species identification is uncertain, a precautionary approach will be taken, and the most conservative option in accordance with the additional management procedures for BW/PBW or SRWs will be followed until identification is otherwise confirmed.

[17] Where 'Attending Support Vessel' means the vessel that is accompanying the Seismic Vessel at close range at any one time. Noting that it could be the support, chase, or supply vessel; but at least one of these vessels is required to be in attendance at any one time.
[18] This distance has been selected on the basis that blue whale detection can be reasonably expected to 5 km over a range of sighting conditions.
[19] This measure is superseded by Additional Management Procedures applicable to BW/PBW and SRW.
[20] When observations cannot extend to 5 km from the acoustic source, e.g. during fog or periods of high winds.
[21] The hours between sunset and sunrise at any given location.
[22] This measure is superseded by Additional Management Procedures applicable to BW/PBW and SRW.

Specific Controls for Blue Whales

Animat modelling has been used to inform the development of the following control measures for blue whales. As the two subspecies of blue whales are difficult to distinguish at sea, these controls will be applied to both subspecies (denoted as **BW/PBW**). This modelling predicts the maximum onset distances for 24-hour cumulative PTS and TTS as 130 m and 32 km respectively. Cumulative TTS effects from acquisition on the continental slope are however only expected to occur to 15.4 km inshore of the active acoustic source on account of reduced sound propagation in the upslope direction. Therefore, acquisition within c. 16 km of the PBW foraging BIAs or within the BIAs themselves has the potential to result in injury or displacement of a BW/PBW from a foraging area[23].

The maximum predicted onset distance for behavioural effects for BW/PBW is 7 km. This distance underpins the Shut-down Zone for BW/PBW. In addition, the 32 km maximum predicted onset distance for TTS has also been utilised in defining several control measures for BW/PBW.

It is noteworthy that the modelling undertaken was conservative, where 1) the worst-case scenarios for noise propagation were modelled to produce maximum estimates of onset distances for TTS and PTS, and 2) the modelled source locations and seasons were those expected to exhibit noise propagation over the greatest distances.

The c. 16 km onset distance for cumulative TTS in the onshore direction has been used to define a buffer zone around the blue whale foraging BIAs (referred to as **BW BIAs** herein). No acquisition will occur within the BW BIAs or the 16 km buffer during the 'peak feeding season' from January to June (inclusive) based on the expected consistent and widespread presence of whales in the foraging areas during these months (Gill *et al*., 2011; 2015; McCauley *et al*., 2018). The only exception allowed is the acquisition of the 2D tie line which will be subject to additional operational restrictions (see **AMP 2** in **Appendix M**) and will only take approximately 12 hours to acquire.

This spatio-temporal measure has been designed to eliminate any physical or behavioural effects on foraging BW/PBW in the designated BW BIAs during the foraging season; hence, to comply with the requirement of the Blue Whale Conservation Management Plan that blue whales can continue to use biologically important areas without injury and no blue whale will be displaced from a foraging area. On this basis, the protection afforded to BW/PBW in the BW BIAs is very strong during the peak months of foraging area use.

Operations inside the BW BIAs and the 16 km buffer (referred collectively as **BW BIAs/buffer** herein and depicted in **Figure 80**) will be permitted outside these months including during the 'foraging shoulder season' months of September to December and July when whales may be present, but densities are expected to be substantially lower and presence is less consistent. All operations inside the BW BIAs/buffer during the foraging shoulder season will be subject to the use of aerial surveys to assist with BW/PBW detection.

Throughout the survey an Extended Observation Zone (as described in **BMP 4** below) will be implemented and will serve the dual purpose of detecting BW/PBWs at extended distances in order to implement the 7 km Extended Shut-down Zone and to assist with survey planning in order to facilitate operational avoidance of areas where BW/PBWs are present. Several adaptive management measures are also proposed.

[23] Defined in the 'Guidance on key terms within the Blue Whale Conservation Management Plan' (published by DAWE in September 2021) as a designated foraging BIA.

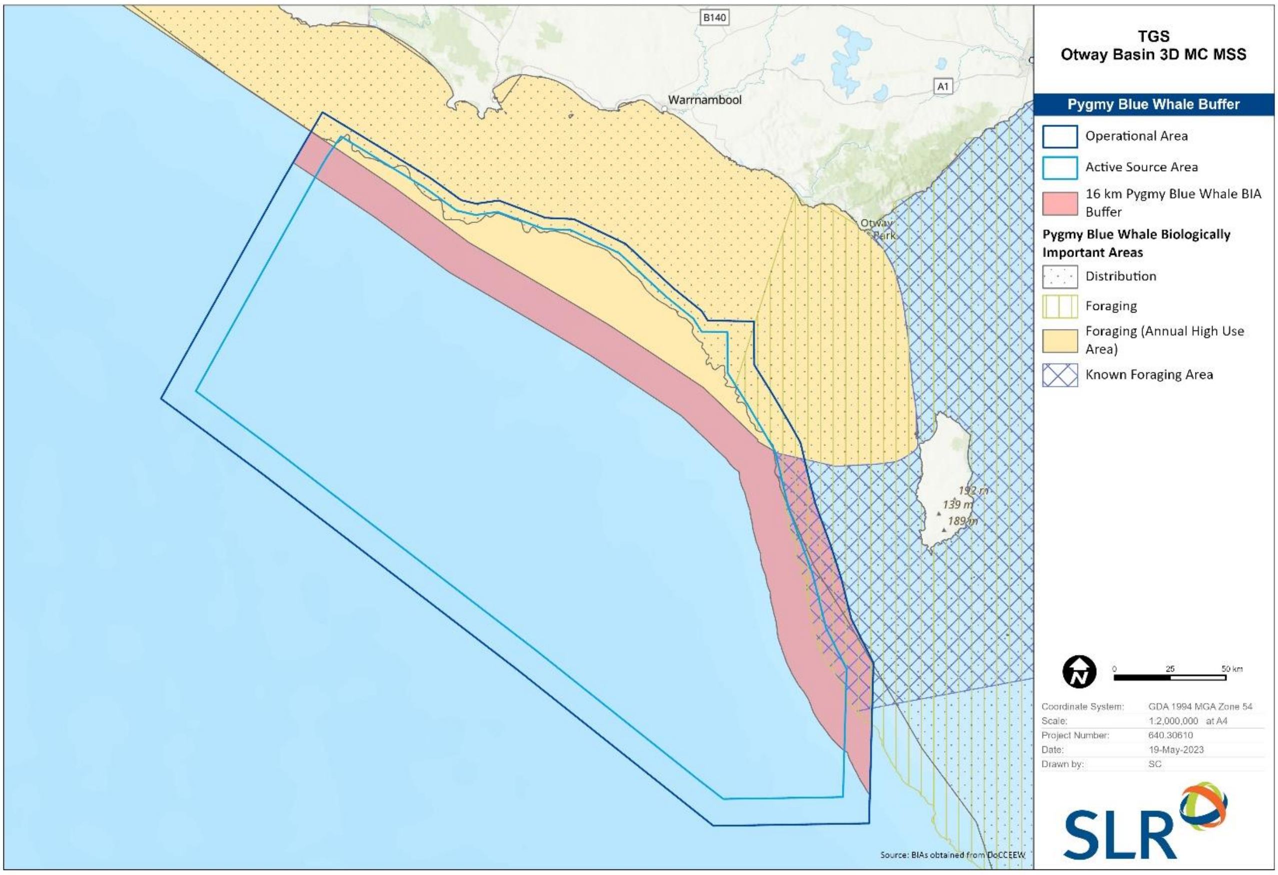

Figure 80   Blue Whale/Pygmy Blue Whale BIAs and 16 km Buffer Zone

In light of the conservative approach taken by the modelling, the proposed controls (as summarised above and detailed below) demonstrate consistency with the objective of the Blue Whale Conservation Management Plan (that "*anthropogenic threats are demonstrably minimised*") and the purpose of the Australian Whale Sanctuary (that cetaceans are not killed, injured, or interfered). On this basis, acoustic injury to BW/PBW can be managed to an acceptable level throughout the OA; hence, anthropogenic threats (as they relate to physiological impacts from underwater noise) are avoided through robust and adaptive management measures.

The following additional and adaptive management procedures for BW/PBW (denoted with **BMP**) will be implemented during the Otway Basin 3D MC MSS:

- BMP 1: A 16 km buffer will be established around all BW BIAs where they overlap or approach the OA.
- BMP 2: The Seismic Vessel will not activate the acoustic source(s) within any BW BIAs/buffer from January to June (inclusive) which represents the peak foraging season during which BW/PBW are expected to consistently be present at foraging areas in and around the OA at elevated densities. The only exception allowed relates to the acquisition of the 2D tie line in accordance with the criteria outlined in **AMP 2** in **Appendix M**.
- BMP 3: A 7 km Extended Shut-down Zone will be implemented for BW/PBW throughout the OA (including the BW BIAs/buffer). On this basis a Low Power Zone is deemed unnecessary.

- BMP 4: An 'Extended Observation Zone' will be adopted such that vessel based MFOs observe for BW/PBWs as far as practicable, and to a minimum of 7 km during daylight hours. During periods when visibility is < 7 km, the Extended Observation Zone will be monitored by the combined efforts of the MFOs on both the Seismic Vessel and at least one Support Vessel travelling approximately 5 – 7 km ahead of the Seismic Vessel. This Support Vessel will focus monitoring efforts on the 90° quadrant that lies directly ahead of the Seismic Vessel, and in reference to these specific duties, is herein referred to as the EOZ Support Vessel. When visibility is > 7 km, this Extended Observation Zone may be monitored solely by MFOs on the seismic vessel. At these times the EOZ Support Vessel will be available to assist with vessel operations and port calls; however, whenever possible the intention is that the EOZ Support Vessel shall maintain its position 5 – 7 km ahead of the seismic vessel to assist with BW/PBW detections. The only permissible exceptions to the specified EOZ Support Vessel duties will be issues of safety that require relocation of the EOZ Support Vessel or in the event of incidents involving significant risk to in-sea equipment when the EOZ Support Vessel will be permitted to temporarily assist providing the following criteria are met:
    a. The MFO onboard the EOZ Support Vessel continues observations for BW/PBWs;
    b. There have been no BW/PBW instigated shut-downs in the preceding 6 hours; and
    c. No more than 4 hours elapse before the EOZ Support Vessel resumes its position ahead of the Seismic Vessel.
- BMP 5: Low Visibility or Night-time Operations may occur provided that no BW/PBW shut-downs have been instigated during the preceding 24 hours within 32 km of the planned acquisition (i.e. the survey lines that will occur during the hours of darkness or the period of low visibility).
- BMP 6: During the 'foraging shoulder season' months of September to December and July the seismic vessel is permitted to operate in the BW BIAs/buffer in accordance with the following protocols:
    a. All reasonable efforts[24] will be made to ensure that aerial surveys will be conducted to assist with the detection of BW/PBW in the BW BIAs/buffer during the 'foraging shoulder season'. Within the seven days prior to commencement of any acquisition in the BW BIAs/buffer aerial surveys will be flown, if possible, to identify any BW/PBWs that may be present. Any such detections will result in acquisition within the BW BIAs/buffers being redirected away from areas in which such detections have been made. The intent of this control is to allow TGS to respond adaptively to detections of BW/PBWs in the BW BIAs/buffer by relocating to parts of the BW BIAs/buffer where potential impacts on BW/PBWs are less likely.
    b. If the requirement for aerial surveys as outlined in (a) above cannot be achieved, no low visibility or night-time operations may occur inside the BW BIAs/buffer until such time as the aerial survey requirement is met.
    c. Aerial survey efforts will concentrate on the area of the BW BIAs/buffer nearest to the proposed start up location and/or those waters that will be subject to acquisition in the first 24 hours of planned seismic operations. Throughout the period in which acquisition is underway, aerial surveys will be flown periodically as weather permits to support the detection of BW/PBW and to redirect seismic survey efforts in order to avoid BW/PBW that are present.
    d. Aerial surveys must be undertaken by two experienced observers from a suitable aircraft. At least one of these observers must demonstrate previous experience in the detection and identification of BW/PBW from the air.
    e. Start-up (via soft start) can only commence in the BW BIAs/buffer during the 'foraging shoulder season' if the following criteria are met:

[24] Noting that in some circumstances aerial surveys may not be possible due to weather or aircraft availability constraints.

i. A minimum of two hours of daylight remain before nightfall;

ii. Good sightings conditions prevail that allow visual observations of the Extended Observation Zone;

iii. MFOs on board the Seismic Vessel and the EOZ Support Vessel have completed at least 30 minutes of pre-start observation procedures and confirmed no BW/PBW have been sighted; and

iv. The start-up location does not occur within 32 km of an area where a BW/PBW detection has been made in the last four days.

- BMP 7: If a BW/PBW is detected in the 7 km Extended Shut-down Zone during the Otway Basin 3D MC MSS the acoustic source will be immediately shut-down and the seismic vessel will relocate to another area at least 32 km away from the last PBW sighting before commencing Pre Start-up Visual Observations and Soft Start Procedures. If relocation of the seismic vessel is not possible[25], then acquisition will cease and will not recommence until 24 hours have elapsed and no BW/PBW has been detected in the 7 km Extended Shut-down Zone.
- BMP 8: A Start-up Delay will occur if a BW/PBW enters or is detected in the 7 km Extended Shut-down Zone during the soft start, and soft start procedures may only resume once the BW/PBW is observed to move outside this Shut-down Zone or when 30 minutes have lapsed since the last BW/PBW sighting.
- BMP 9: If higher than anticipated numbers of BW/PBW are observed (three or more BW/PBW instigated shut-downs are made during the preceding 48 hour period[26]) at any time or location during the Otway Basin 3D MC MSS, the following adaptive management controls will apply:

  a. Acquisition in the BW BIAs/buffer must cease;

  b. Low Visibility or Night-time Operations must cease; and

  c. Normal operations may only resume after 24 hours of no BW/PBW instigated shut-downs.

Specific Controls for Southern Right Whales

Animat modelling has been used to inform the development of control measures for SRW. This modelling predicts the maximum onset distances for 24-hour cumulative PTS and TTS as 40 m and 11 km respectively. Based on these results, TTS effects are not predicted to extend from the OA into the Aggregation BIA (which occurs 14 km north of the OA) or any of the connecting habitat, migration and resting on migration BIAs that occur further afield in coastal waters. The predicted onset distances for behavioural effects for SRWs are significantly larger than those predicted for hearing injury. On this basis, the proposed controls for this species are comprehensively discussed in **Section 7.2.2.3.6** - Potential Behavioural Effects. However, the key controls that will contribute to managing potential physiological effects on SRWs are summarised below:

- A 42 km buffer will be established around the SRW Aggregation BIA where it approaches the OA.
- A spatio-temporal closure will be implemented that prohibits acquisition within 42 km of the SRW Aggregation BIA (**Figure 81**) during the core aggregation months of May to September (inclusive);

[25] For instance, towards the end of the survey when few survey lines remain to be acquired.
[26] Note that any unidentified whale/s will contribute to this count.

- Extended Shut-down Zones will be implemented for SRWs, whereby 1) shut-downs will be triggered by a SRW sighting out to 7 km inside the SRW Aggregation BIA and 42 km buffer during the aggregation shoulder season (April and October); and 2) shut-downs will be triggered by a SRW sighting out to 3 km throughout the remainder of the OA and inside the SRW Aggregation BIA and 42 km from November to March;
- Additional restrictions on acquisition during the shoulder aggregation months of April and October will be required, including the use of aerial surveys to assist with SRW detection, the implementation of extended observation zones, limitations on the timing of soft-starts, and limitations on low visibility and night-time operations; and
- Strong adaptive management measures (including relocation of the Seismic Vessel following any SRW detection) have also been developed to minimise potential noise effects on SRWs throughout the OA.

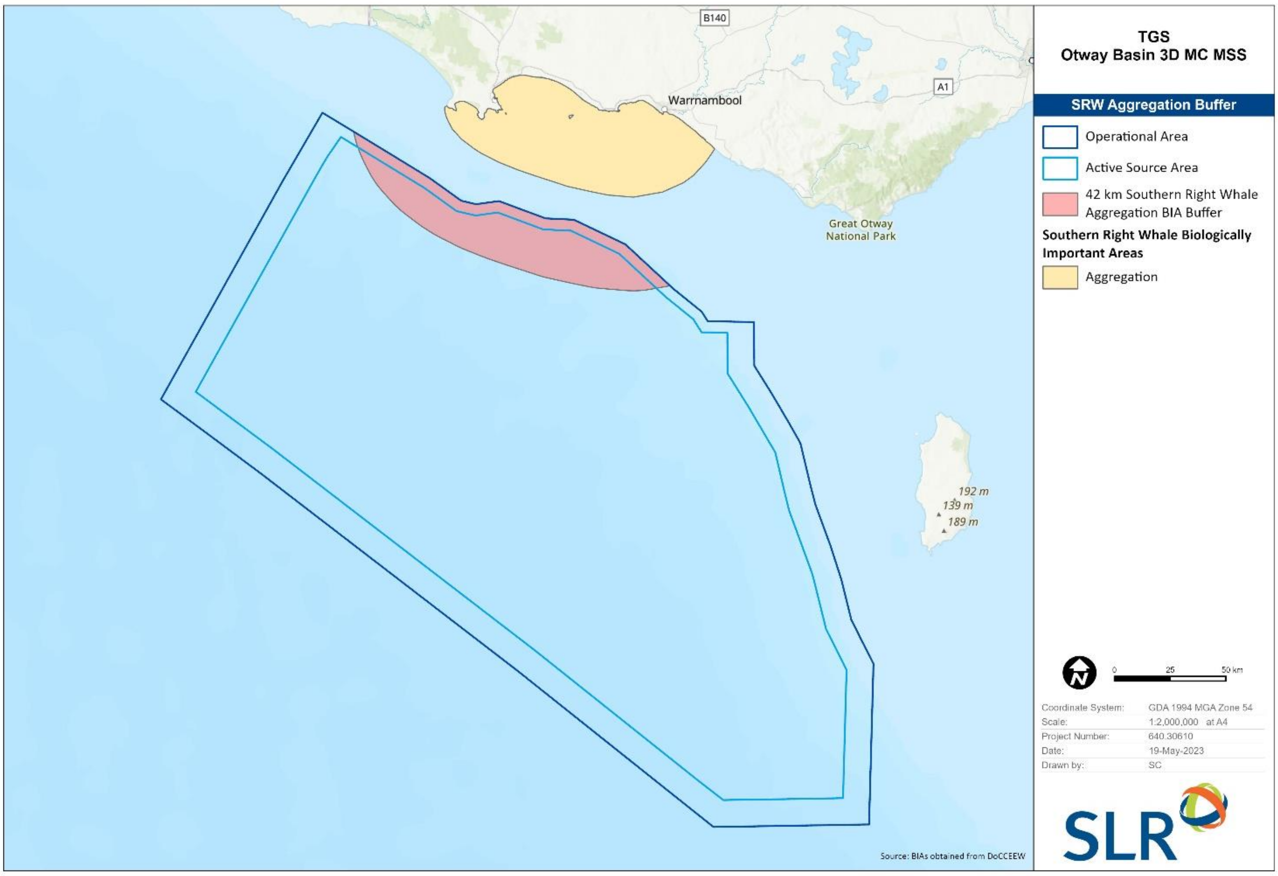

Figure 81 SRW Aggregation BIA and 42 km Buffer Zone

Specific Controls for Other Whales

In accordance with Policy Statement 2.1, the term 'whale' refers to baleen whales and other large, toothed whales such as, sperm whales, killer whales, false killer whales, pilot whales and beaked whales.

For clarity, all whale species other than BW/PBW and SRW are herein referred to as 'other whales', meaning:

- All baleen whales excepting BW/PBW and SRW; e.g. humpback, fin, sei, Bryde's, pygmy right, and minke whales; and

- All large, toothed whales; e.g. sperm whales, killer whales, false killer whales, pilot whales, pygmy sperm whale, dwarf sperm whale, and beaked whales; and
- The spectacled porpoise.

The measures that are specific to 'other whales' have been developed on the basis that free-ranging pelagic animals are not expected to remain in the vicinity of the Seismic Vessel for extended periods and the movement of the Seismic Vessel means that any potential exposure will be transitory in nature.

For 'other' baleen whale species (i.e. all other species of baleen whale, excluding blue whales and SRWs), the UAM results (**Table 70**) predict that 24-hour cumulative PTS could occur out to a maximum of 500 m, but that exposure to a single pulse from the active acoustic source would not elicit PTS even if an animal was very close to the source (< 20 m). The maximum onset distance for 24-hour cumulative TTS is predicted to be 156 km while the single pulse onset distance for TTS is 70 m. It is noteworthy that UAM results show a high degree of variance between modelling scenarios, and, unlike the animat modelling, they do not account for animal movement. While the onset distance for cumulative TTS is large (156 km), the likelihood of this occurring is considered to be low on account of both Seismic Vessel movement and the free-ranging nature of any exposed animals.

While the following other baleen whale species could have a potential presence in the OA (see **Section 4.5.6**): humpback, fin, sei, Antarctic minke, and pygmy right whales, these species are generally expected to be migrating or transient, and no designated BIAs for aggregations of these species exist within the OA. A summary of distribution and density for these species in relation to the OA is provided in **Table 73**.

Table 73 Other Baleen Whales and their Distribution and Density in the OA

Species	EPBC Protected Matters Database; presence ranking in OA	Distribution and Density Considerations
Humpback whale	Known	The OA does not overlap with the well-defined migration routes that occur along the west and east coasts of Australia; hence, densities in and around the OA are expected to be comparatively low. Humpback whales do however occur as frequent visitors to VIC waters including Bass Strait and beyond into SA. Feeding has been observed in the Bonney Upwelling and off Portland particularly during the south-bound migration period of September-October (Gill *et al.,* 2015; SWIFFT, 2021c
Fin whale	Known	Distributional information is limited, but this species has been observed feeding in the Bonney Upwelling between November and May (Gill *et al*., 2015). While a seasonal presence (July to October; Aulich *et al*., 2019) is assumed for in and around the OA, Aulich *et al*., (2022) presented data to suggest presence here is inconsistent and irregular and densities off the south coast of Australia are very low.
Sei whale	Known	Distributional information is very limited but a small number of sightings have been reported from VIC waters and those off TAS (Kato *et al.,* 1996; Gill, 2002), mainly during summer and early autumn months (Gill, 2002). Feeding in the Bonney Upwelling has been observed, but based on the relatively low incidence of sightings, densities of this species are likely to be low..

Species	EPBC Protected Matters Database; presence ranking in OA	Distribution and Density Considerations
Antarctic Minke Whale	Likely	Distributional information is very limited but one possible sighting was made in the vicinity of the OA during an aerial survey (Gill *et al*., 2015). Abundances of this species in Australian waters are though to peak in July and August (Arnold *et al*., 1987), but densities in and around the OA are assumed to be very low based on the rarity of sightings.
Pygmy right whale	Likely	This species is known to occur in the Bonney Upwelling region, although almost all sightings occur within 2 km of the shore (Kemper *et al.,* 2013). Sightings were most frequent from September to February and included feeding behaviours. An additional peak in occurrence was apparent in June (Kemper *et al*., 2013, Gill *et al.,* 2008). No information is available on which to assess densities, but the available data suggests that offshore densities are likely to be lower than inshore waters

On the basis that other baleen whales are 1) probably only present in the OA at relatively low densities and are likely to swim away from the approaching seismic source and 2) UAM does not account for animal movement, it is considered that the 24-hour cumulative UAM results are unrealistic and excessively conservative for defining the extent of observation or shut-down zones for other baleen whales. Although animat modelling has not been undertaken for the species listed in **Table 73**, it is likely that the actual PTS and TTS ranges for these species would be of a similar magnitude to those calculated for PBWs e.g. accumulated exposures may result in PTS effects within tens or a few hundreds of metres from the acoustic source, while TTS effects may extend up to a few tens of kilometres. On this basis, PTS and TTS as a result of cumulative exposures are unlikely to occur and even if TTS were to occur for other baleen whale species, it would be temporary and recoverable. Despite this, the controls as outlined earlier (**MP 1 – 10**) will apply to other whales, including a 2 km Shut-down Zone that will provide excellent protection to baleen whales from all potential PTS effects. In addition, 'Adaptive Management Procedures' and 'Additional Management Procedures for Other Whales' have also been proposed. These are fully described in **Appendix M** and include limitations on start-up procedures at night and during periods of low visibility, and the requirements for MFO use. Further to this controls to address potential behavioural effects to baleen whales are discussed in **Section 7.2.2.3.6**.

Odontocetes (toothed whales and dolphins) mostly belong to the HF hearing group, and as noted in **Table 25** numerous species could potentially occur in the OA, with those species 'known' or 'likely' to be present in the OA and EMBA being sperm whales, killer whales, false killer whales, long-finned pilot whales, dusky dolphins, common dolphins and bottlenose dolphins. Hearing of HF cetaceans is less sensitive to low frequency seismic sound than baleen whales. Effects ranges are therefore significantly reduced for HF cetaceans compared with LF cetaceans (**Table 70**). For HF cetaceans, PTS thresholds are not exceeded and the maximum predicted distance to the 24-hour cumulative TTS effects threshold is only 100 m. This is not a credible scenario, as a dolphin would not remain within 100 m of the seismic source or for a 24-hour period; hence physiological injury is not predicted for HF cetaceans and no specific controls are proposed.

Three species of VHF cetacean have been identified as having a potential presence in and around the OA - the pygmy sperm whale and dwarf sperm whale and the spectacled porpoise. Overall, the risk to VHF cetaceans is limited given their reduced sensitivity to low-frequency seismic sound. The maximum horizontal ranges predicted by modelling (**Table 70**) to exceedance of PTS and TTS thresholds for VHFC are 360 m and 680 m respectively for single impulses. Based on the SEL_{24h} thresholds, the potential for PTS is predicted to be limited to within 110 m from the source, and TTS within 850 m of the source. While a cetacean won't realistically remain within 850 m of the source for long enough to experience TTS from accumulated sound exposures, the results highlight that hearing impairment could occur as a result of exposure to a single impulse in some circumstances.

Implementation of management procedures (**MP 1 – MP 10**) listed earlier in the section will minimise the likelihood of hearing injury impacts occurring. In addition, all VHF cetacean species expected in the OA (pygmy sperm whale, dwarf sperm whale and spectacled porpoise) are included in the definition that has been adopted for 'other whales'. In particular, the inclusion of the spectacled porpoise in this definition ensures that all VHF cetaceans that could be present in the OA are afforded additional protection over that which would have been offered by the standard requirements of the EPBC Act Policy Statement 2.1. This approach aligns with the precautionary approach and has been adopted to protect these species from the potential for permanent hearing damage which the modelling results indicated was possible from a single impulse out to 360 m. This approach also ensures consistency with the requirements of the Australian Whale Sanctuary. Further to this, a passive acoustic monitoring (**PAM**) system will run 24-hours per day on the Seismic Vessel during the Otway Basin 3D MC MSS, with dedicated, trained, and experienced PAM Operators conducting acoustic monitoring for the presence of cetaceans while the acoustic source is active and during the 30 minutes before the commencement of any Soft Start Procedure.

A comprehensive list of controls to address all potential effects of underwater noise on marine mammals are presented in **Appendix M** and **Table 84.**

Assessment Summary – Physiological Effects on Blue Whales

The BW Conservation Management Plan includes the following action: "*Anthropogenic noise in biologically important areas will be managed such that any blue whale continues to utilise the area without injury and is not displaced from a foraging area*" (see Action Area A.2). In addition, one of the recovery plan interim objectives (Interim Objective 4) is that "anthropogenic threats are demonstrably minimised" and in particular "*Robust and adaptive management regimes leading to a reduction in anthropogenic threats to Australian blue whale are in place*" (Target 4-1). Associated Guidance on key terms within the BW Conservation Management Plan (published by DAWE in September 2021) clarifies that:

- "Injury": For the purpose of interpreting and applying Action Area A.2 of the BW Conservation Management Plan, injury includes both PTS and TTS.
- "Foraging Area": Designated foraging BIAs
- "Displaced from a Foraging Area": A whale is considered to be 'displaced' from a "Foraging Area" if foraging behaviour is disrupted, regardless of whether the whale can continue to forage elsewhere within that Foraging Area. I.e. noise should not:
  - Stop or prevent any blue whale from foraging;
  - Cause any blue whale to move on when foraging; or
  - Stop or prevent any blue whale from entering a Foraging Area
- Mitigation measures must be implemented to reduce the risk of displacement occurring during operations where modelling indicates that behavioural disturbance within a Foraging Area may occur.
- A precautionary approach should be taken to the management of industry activities proposed to occur in or adjacent to designated BIAs (Foraging Areas) due to the increased likelihood of whales foraging in those locations at critically important times.
- Activities proposed to occur outside designated BIA (Foraging Areas) must adopt best practice adaptive management approaches in the event that indicators of whale foraging (such as aggregating in a particular area) are evident to ensure that impacts to whales are not unacceptable e.g. injury or displacement.

- Noting the potential for whale foraging and feeding to occur in areas of high primary productivity outside of designated Foraging Areas, consideration also needs to be given to management of industry activities and underwater anthropogenic noise where opportunistic foraging potential exists. In areas other than designated BIAs (Foraging Areas), where it can be reasonably predicted that blue whale foraging is probable, known or whale presence is detected, adaptive management should be used during industry activities to prevent unacceptable impacts (i.e. no injury or biologically significant behavioural disturbance) to blue whales from underwater anthropogenic noise. In-field observations of actual whale feeding are difficult to detect, so indicators of probable foraging should be used as a proxy.

Therefore, the requirements of the BW Conservation Management Plan provide a precautionary approach, whereby potential injury or displacement of individual animals should be avoided, not just impacts at a population level.

Based on the animat modelling results, it is apparent that un-mitigated acquisition in the Bonney Upwelling region during the PBW foraging season would present a high likelihood of TTS effects and disruption to foraging behaviours (both inside and outside designated BIAs). On this basis, un-mitigated acquisition in the OA between September and July would be inconsistent with the BW Conservation Management Plan, which sets precautionary requirements based on the critically endangered status of the species. Instead, and to ensure consistency with the BW Conservation Management Plan, a comprehensive suite of control measures (as described earlier by **BMP 1 – 9**) are proposed to reduce the potential of such impacts occurring.

By implementing these controls, the potential for physiological effects (i.e. hearing injury) to endangered blue whales is significantly reduced throughout the OA. In particular, the spatio-temporal measures that will largely preclude operations in the BIAs during biologically important times have been designed to eliminate potential physiological effects on foraging BW/PBW in the designated BW BIAs during the peak foraging season; hence, to comply with the requirement of the BW Conservation Management Plan that individual whales can continue to use biologically important areas without injury. The spatio-temporal controls that will be implemented in and around the BW BIAs represent best international practise for minimising underwater noise disturbance in areas of high density and biological importance during key periods (following Chou *et al*., 2021). Further to this, the proposed control measures for BW/PBWs are in accordance with the DAWE Guidelines (2021) which define injury as both permanent and temporary hearing impairment.

In addition to the controls proposed for acquisition within the BW BIAs/buffer, a 7 km Extended Shut-down Zone will be implemented for BW/PBW throughout the OA; hence no PTS is expected as this shutdown distance significantly exceeds the predicted PTS onset distance of 130 m. The potential for any BW/PBW to experience cumulative TTS is also limited given that the movement of the Seismic Vessel (7.4 – 9.3 km/hr) will mean that continuous exposure to injurious operational noise for 24-hours is unrealistic as the seismic vessel will be well beyond the 32 km TTS onset distance within c. 4 hours. Strong adaptive management control measures are also proposed for BW/PBWs throughout the entire OA; hence physiological effects on blue whales can be managed to an acceptable level at all times and locations during the Otway Basin 3D MC MSS.

Assessment Summary – Physiological Effects on Southern Right Whales

As described earlier in this section and based on the Animat modelling results (maximum onset distances for 24-hour cumulative PTS and TTS of 40 m and 11 km respectively), physiological effects for this species are not predicted to extend into the SRW Aggregation BIA (which occurs 14 km north of the OA) or any other inshore connecting habitat, or migration and resting on migration BIAs that occur further afield in coastal waters. Indeed, the predicted onset distances for behavioural effects for SRWs are significantly larger than those predicted for hearing injury, hence these larger onset distances have been used to inform the development of control measures for this species (see **Section 7.2.2.3.6**).

While it is acknowledged that another designated ‘known core range’ BIA for SRWs occurs in the area, the OA only marginally overlaps with this BIA and individual SRWs are expected to traverse this area on their way to and from the more coastal aggregation areas and connecting habitat in which periods of semi-residency and less directional movements are expected. In this context it is noteworthy that throughout the OA, a 7 km Extended Shut-down Zone will be implemented; hence no PTS is expected as this shut-down distance significantly exceeds the predicted PTS onset distance of 40 m. Further to this, the potential for any SRW to experience cumulative TTS is limited given that the collective movement of any individual whale (1.1 km/hr; Burnell, 2001) and the Seismic Vessel (7.4 – 9.3 km/hr) will mean that continuous exposure to injurious operational noise for 24-hours is unrealistic as the seismic vessel will be well beyond the TTS onset distance within 1 – 2 hours. As described in **Section 7.2.2.3.6** no acquisition will be permitted within 42 km of the SRW Aggregation BIA from May to September. In addition, the implementation of strong adaptive management measures throughout the entire OA will significantly minimise the potential for any physiological effects on this species.

The proposed control measures support the recovery objective of the SRW Conservation Management Plan that “*The long-term recovery objective is to minimise anthropogenic threats to allow the conservation status of the southern right whale to improve so that it can be removed from the threatened species list under the EPBC Act*” and Interim Recovery Objective 5 that “*Anthropogenic threats are demonstrably minimised*”.

Assessment Summary – Physiological Effects on Other Whales

While the additional management procedures for other whales eliminate the risk of PTS, they do not eliminate the risk of baleen whales being subject to cumulative TTS during the Otway Basin 3D MC MSS. However, the extended 2 km Shut-down Zone provides strong protection from short-term exposure to high levels of underwater noise and both vessel and animal movement will ensure that the likelihood of physiological impacts on other whales remains low. While the potential for temporary hearing damage to individual whales cannot be dismissed, this would only occur if a whale went undetected inside the proposed precaution zones or if they remained in the general vicinity of the active source for 24-hours.

In accordance with the precautionary approach and to ensure compliance with the purpose of the Australian Whale Sanctuary that cetaceans are not killed, injured, or interfered, the proposed control measures for ‘other whales’ will also apply to the spectacled porpoise for the purpose of this survey. Despite exceeding the requirements of Policy Statement 2.1, this provision addresses the potential for hearing injury to VHF cetacean species even from a single seismic impulse.

7.2.2.2.7.1 Conclusion – Physiological Effects on Marine Mammals

Given their sensitivity to low frequency sound, the risk of physiological effects associated with underwater noise exposure from seismic operations is greatest for baleen whales (LF cetaceans). In general, the potential for TTS effects extends over significant distances for baleen whales but the transient nature of many of these species mean that significant levels of TTS are unlikely to occur, or if it does the effects are recoverable and unlikely to impede the individual's survival. Long term impacts to populations are not predicted. However, it is acknowledged that the potential risk to endangered PBWs and SRWs, which both aggregate in the region to forage or to rest and calf, is greater. On this basis a comprehensive suite of control measures has been developed for these species to reduce the potential of such impacts occurring.

Based on the information outlined in this section, the residual risk to whale physiology (both LF cetaceans and VHF cetaceans) from underwater noise generated by the proposed Otway Basin 3D MC MSS has been assessed as **Low** (*Minor* x *Unlikely*) as no detectable adverse effects to whale populations or significant physiological effects to individuals from any endangered species are predicted.

The risk to odontocetes (toothed whales, which are largely categorised as HF cetaceans) and otariid seals (fur seals and sea lions) is substantially lower. Policy Statement 2.1 does not require any shut-downs for dolphins or seals, so theoretically, these species could be subject to physiological effects under some circumstances, but the UAM results for HF cetaceans and otariids (**Table 70**) indicate that no PTS is expected and TTS would only occur after prolonged exposure within 100 m of the active source. The likelihood of such prolonged exposure is however virtually nil in free-ranging pelagic animals, and seals have the added advantage of being able to swim with their heads above water to avoid loud underwater noise (Mikkelsen *et al*., 2017). Consequently, the residual risk to the physiology of HF cetaceans and otariids from underwater noise during the Otway Basin 3D MC MSS has been assessed as **Negligible** (*Negligible* x *Rare*) and no specific control measures are warranted.

7.2.2.2.8 Seabirds

Since high intensity acoustic disturbances such as those from an MSS have the potential to cause physiological harm to marine mammals and fish, it is reasonable to assume that seabirds could also suffer physiological damage. Seabirds resting on the sea surface are typically startled by an approaching Seismic Vessel and would therefore be displaced from the immediate vicinity of the acoustic source, limiting their exposure to seismic emissions. Birds on the sea surface are unlikely to suffer physiological effects as the Lloyd Mirror effect means that noise levels at the surface are lower than those deeper in the water column (Carey, 2009).

Physiological damage might only occur to those seabirds within the OA that exhibit diving behaviours, and which are in extremely close proximity to the acoustic source. Due to their largely aquatic existence and lack of flight ability, seabirds such as little penguins are expected to be more susceptible to effects from MSSs than other seabirds though they are not anticipated to occur within the OA (Pichegru *et al*., 2017).

Seabirds chase small bait fish as their prey, and it is likely that these small fish would be displaced from the immediate vicinity of the active acoustic source (see **Section 7.2.2.3.2**). Seabirds are expected to detect this change in fish distribution and cease any foraging, which would in turn reduce their exposure to any potential physiological effects.

To date there is limited evidence of physiological effects of MSSs on seabirds, with all documented effects limited to behavioural effects (see **Section 7.2.2.3.7**).

Consequently, the residual risk to seabird physiology arising from acoustic disturbance during the Otway Basin 3D C MSS has been assessed as **Low** (*Minor* x *Rare*).

7.2.2.3 Potential Behavioural Impacts

Behavioural responses are a demonstrable change in the activity of an animal in response to a disturbance (Nowacek *et al.,* 2007) and include movement away from an area to avoid a disturbance, or a change in normal behaviours such as diving, respiration, and swimming speed. In addition to avoidance responses, some animals may be attracted to areas of disturbance. The most commonly observed behavioural response to active MSS operations is avoidance, which has been widely documented for marine mammals (e.g. Goold, 1996; Stone and Tasker, 2006; Thompson *et al*., 2013) and fish (e.g. Engas *et al*., 1996; Slotte *et al*., 2004), and which can lead to the displacement of animals from preferred habitat.

Displacement from an area can lead to relocation into sub-optimal or high-risk habitats, resulting in negative consequences such as increased exposure to predators, decreased foraging or mating opportunities, alterations to migration routes etc. Displacement could also have indirect effects, for instance feeding activities of predators could be disrupted by the displacement of prey species which could lead to energetic consequences.

Discussions on the behavioural impacts from vessel noise and the acoustic source on marine fauna are provided in the subsections below for each environmental receptor. Where possible, discussions have paid particular focus to species that have been identified to be potentially present within the OA/AA through the development of this EP. Perceptual impacts (i.e. changes in vocalisations and masking) are discussed in **Section 7.2.2.4** while physiological impacts have been addressed in **Section 7.2.2.2**.

7.2.2.3.1 Benthic Invertebrates

Benthic invertebrates, particularly fixed or sessile benthic organisms, generally have far lower mobility than pelagic vertebrates, and are often associated with particular habitats. As such, they generally have less ability to avoid an approaching acoustic source. However, invertebrates are generally considered to have limited sensitivity to sound. Marine invertebrates lack a gas-filled bladder and are unable to detect the pressure component of sound waves (Parry and Gason, 2006; Carroll *et al*., 2017) or "hear" sound in the way that mammals and fish can. Instead, invertebrates detect sound by sensing the particle motion component of sound in water and seabed sediments through physiological structures such as sensory hairs, statocysts and muscles, and therefore detect sound at close range (McCauley, 1994; Parry and Gason 2006; André *et al*., 2016; Roberts *et al*., 2016; Edmonds *et al*., 2016; Carroll *et al*., 2017; Popper and Hawkins, 2018). Statocysts are utilised by many invertebrates to maintain their orientation, direct their movements through the water, and may play a key role in controlling the behavioural responses of invertebrates to stimuli.

Exposure to seismic sound can elicit various behavioural responses in benthic invertebrates. Hawkins *et al*. (2015) reports that, at lower sound levels, behavioural responses are more likely to occur than physical and/or physiological responses. Behavioural responses are, however, the most difficult to monitor *in situ* and consequently, many studies investigating the effects of seismic operations on the behaviour of benthic invertebrates are conducted under laboratory conditions or by deploying caged individuals in the field (Carroll *et al*., 2017).

Behavioural responses have the potential to adversely affect a population by, for example, reducing foraging and/or predator avoidance rates. Conversely, they may elicit responses that are brief and pose no overall risk (e.g. a startle response). Research has shown that avoidance behaviours to sound have longer-lasting effects on populations than startle responses. For example, in the former, individuals may move away from an area where MSSs have occurred.

Carroll *et al*. (2017) provided a summary of the potential impacts of low frequency sound on the behavioural responses of marine invertebrates based on a review of the relevant literature. For decapods, foraging, reproduction, and bioturbation response at unrealistic or unknown exposure levels were each reported by one study; three studies reported a possible response, conflicting or anecdotal results with respect to predator avoidance; two studies reported a possible response, conflicting or anecdotal results for startle response; and one study reported no response to sound avoidance.

A range of different habitat/substrate types, and consequently benthic communities will be present in the AA. The seabed of the shelf edge and slope (180 m - >500 m) is expected to consist of muddy carbonate sands and rocky reefs, which disappear with depth (Williams *et al*., 2009). The shelf edge is intersected by canyons and gullies consisting of unconsolidated sediments. The hard substrates and rocky reliefs provide attachment points for a broad range of sessile epifauna, whereas infauna can be found within the sediments. The continental shelf is likely to be sparsely covered by macroalgae, sessile filter feeders (e.g. sponges, bryozoans, bivalves, scallops, stalk crinoids, soft corals), mobile macro-invertebrates (e.g. echinoderms, crustacean) and bioturbating infauna (e.g. annelids) (Hosack and Dambacher, 2012; Williams *et al*., 2009). There are infrequent accounts of octocorals on the continental shelf and deep-water corals in water depths less than 1,000 m. Benthic communities found within the Zeehan AMP include large sponges, lace corals and other sessile filter feeders.

The topography and bathymetry of the West Tasmania Canyons KEF support a high biodiversity of benthic invertebrates. The canyon heads are associated with a high cover of sponges and bryozoans, with the greatest diversity between 200 m and 350 m depth (Schlacher *et al*., 2010). Mobile epifauna (e.g. decapods) are found at rock terraces within the canyons at 300 m to 500 m depth, and bioturbating infauna found below 500 m in muddy sediments (Williams *et al*., 2009).

The particular values and sensitivities with the potential to be impacted by underwater noise are:

- Benthic invertebrate communities of the continental shelf edge, slope and abyssal plane, including sponge communities associated with the West Tasmania Canyons KEF;
- Commercially significant southern rock lobster (*Jasus edwardsii*); and
- Commercially significant giant grab (*Pseudocarcinus gigas*).

Crustaceans

Crustaceans (including lobsters and crabs) detect sound vibrations at close range through their statocysts. Several studies have been undertaken on decapod crustaceans (lobsters, crabs, prawns), both in Australia and internationally, with a range of effects to no effects identified, though none have found any evidence of increased mortality due to acoustic impacts from seismic exposure. Robert and Elliot (2017) reviewed research on particle motion effects to invertebrates, specifically vibration in the seabed, noting studies on particle motion reception in crustaceans, including Goodall *et al*. (1990) who studied the response threshold of Norwegian scampi to acoustic stimuli. It was found that the source of the vibration had to be <1 m away (in the acoustic near field) to initiate a response, confirming that the subjects were detecting particle motion, greater in the near field, rather than pressure. Distinct and reliable responses were exhibited in both the laboratory and the field in response to certain stimuli at low frequencies of 20–200 Hz and ground accelerations of 0.01 – 1.4 m/s2. The sensitivity of the receptor systems in crustaceans has been noted to be much less compared to fish (up to 105 times lower in terms of particle velocity) (Goodall *et al.,* 1990; Fay and Simmons, 1998).

A pilot study on snow crabs (the most commercially valuable fishery off Newfoundland and Labrador) exposed captive adult male crabs and egg-bearing female crabs to approximately 197–237 dB re 1 µPa PK-PK and SELs of <130–187 dB re 1 µPa².s (Christian *et al*., 2003). Caged animals on the ocean bottom at a depth of 50 m were monitored with a remote video camera during exposure to seismic sound and did not exhibit any overt startle response during the exposure period. None of the animals left the immediate area after exposure to the seismic survey sound. Five animals were captured in the snow crab commercial fishery the following year, one at the release location, one 35 km from the release location, and three at intermediate distances from the release location.

Cote *et al.* (2020) investigated the effects of 2D seismic acoustic emissions on the behaviour of free-ranging adult male snow crabs using a multi-year Before-After-Control-Impact approach. Cote *et al.* (2020) found the magnitude of effects on the behaviour of exposed snow crabs were at most small or not statistically relevant.

Payne *et al.* (2007) conducted a pilot study of the effects of exposure to seismic sound on various health indicators of American lobster. Adult lobsters were exposed at approximately 2 m range from a seismic source for either 20 or 200 times to average pressures of 202 dB re 1µPa PK-PK or 50 times to 227 dB re 1µPa PK-PK, and then monitored over several months for changes to survival, food consumption, turnover rate, and serum biochemistry. There were no observations of limited ability of lobsters to right themselves when turned over following exposure. There was evidence of a decrease in serum enzymes and increases in food consumption in the weeks to months post exposure, which may indicate stress effects or potential osmo-regulatory disturbance. Payne *et al*. (2008) did not observe any startle responses in aquarium experiments with lobsters and shrimp exposed to approximately 200 dB re 1µPa PK-PK.

Christian *et al*. (2003) examined the behaviour of snow crabs before, during and after exposure to seismic outputs and observed that, in the laboratory, they reacted slightly when sharp sounds were made near them. However, in the field, caged crab showed no readily visible reactions to the 200 in^3 acoustic source 50 m above them. Tagged crabs did not undergo any large-scale movements out of the area.

For decapods, alarm response to sound have been shown to be highly localised, with alarm behaviour occurring only when they were <10 cm away from the sound source (Goodall *et al*., 1990) and they have shown no such behaviour in response to seismic sound at distances of 1 m or more (Goodall *et al*., 1990; Christian *et al*., 2003).

TAS Giant Crab representatives engaged with during the preparation of this EP state that fishing for giant crab sometimes occurs at depths greater than 400 m. Following feedback during the relevant persons engagement process, in order to protect giant crab within deeper habitats within the OA and AA, TGS will implement a Giant Crab Acoustic Exclusion Area (**Figure 74**), within which there will be no activation of the acoustic source. This area covers the waters along the eastern boundary of the OA and AA that are 1,000 m or less and will protect giant crab habitat from the highest acoustic emissions.

Molluscs and Echinoderms

Molluscs include marine bivalves (e.g. scallops, oysters, mussels, and clams) and gastropods (e.g. sea snails, and abalone). Echinoderms include star fish, sea urchins and sea cucumbers. Like crustaceans, the mechanism of impacts for molluscs and echinoderms are unlikely to be from sound pressure, but rather from particle motion. The physiology and sensory structures of different bivalves and echinoderms is similar and so results of studies on the effects of seismic are broadly representative for species other than those studied.

Wardle *et al*. (2001) monitored molluscs and echinoderms on a shallow water reef exposed to seismic sound with peak sound pressure levels of 218, 210 and 195 dB re 1 µPa at distances of 5 m, 16 m and 109 m respectively. Video observations made over two weeks indicated that the sound did not result in invertebrates moving away from the reef and there was little effect on their day-to-day behaviour.

There is a lack of information with regards to the behavioural effects of MSSs on shellfish. As reported by Carroll *et al*. (2017), two studies have shown evidence of a startle response in bivalves at realistic sound exposure levels (Day *et al*., 2016a; Roberts *et al*., 2015), although only one of these studies used seismic outputs as the sound source. Day *et al*. (2016a) reported that scallops exposed to seismic outputs display a distinctive flinching response, an increase in burial rate and were slower at righting themselves than control scallops. It is possible that the slowed righting response could lead to higher predation rates; however, the ecological implications of this are not clear. No energetically costly responses, such as swimming, have been observed in scallops as a result of exposure to an acoustic source.

It is acknowledged that other invertebrate species are also of significance to commercial fisheries in the broader region, including scallops (*Pecten fumatus*) and various species of abalone. However, no impacts to these species are expected. Commercial scallops are targeted by the BSCZSF, primarily over scallop beds near King Island and Flinders Island. Commercial scallops are mainly found at depths of 10 – 20 m but may also occur down to 120 m. Abalone are targeted by divers in the State abalone fisheries. Greenlip abalone are found at depths ranging from 5 – 40 m and blacklip abalone are generally found in waters ranging between 5 – 20 m (PIRSA, 2012). Abalone larval dispersal and adult movements are generally limited to spatial scales of less than one kilometre with the larvae tending to settle near their parental reefs (Prince, 2005; Morgan and Shepherd, 2006; Miller *et al*., 2008; Mayfield *et al*., 2014; Daume *et al*., 2016). Based on the depth distribution of commercial scallops and abalone, the localised effects of seismic emissions on the behaviour of benthic invertebrates are not expected to impact areas where these species occur.

Sponges, Corals and Soft Filter-feeders

Hastings *et al*. (2008), and Battershill *et al*. (2008) investigated the effects of the Woodside Maxima 3D MSS on hard corals in water depths of approximately 40 – 60 m within south Scott Reef lagoon. Corals received maximum sound pressure levels of 226 dB re 1µPa PK. No change on soft coral abundance was detected and there was no evidence of a behavioural response, such as polyp withdrawal or flaccidity (Battershill *et al*., 2008; Heyward *et al*., 2018).

The 226 dB re 1µPa PK is adopted in this assessment as an indication of no effects to benthic filter feeders, such as sponges and temperate corals.

Summary of Behavioural Impacts on Benthic Invertebrates from Acoustic Emissions

Although formal 'no impact' threshold criteria do not currently exist for benthic invertebrates exposed to seismic sound emissions, the research detailed above provides an indication of the types of impacts that may occur and the associated sound pressures. The majority of research indicates that impacts to marine invertebrates (if any) are limited to within a few metres or a few tens of metres of the seismic source, at most.

TAS Giant Crab Fishery representatives engaged with during the preparation of this EP state that fishing for giant crab sometimes occurs at depths greater than 400 m. Following feedback during the relevant persons engagement process, in order to protect giant crab within deeper habitats within the OA and AA, TGS will implement a Giant Crab Acoustic Exclusion Area (**Figure 74**), within which there will be no activation of the acoustic source. This area covers the waters along the eastern boundary of the OA and AA that are 1,000 m or less and will protect giant crab habitat from the highest acoustic emissions.

It is acknowledged that other invertebrate species are also of significance to commercial fisheries in the broader region, including scallops (*Pecten fumatus*) and various species of abalone. However, based on the depth distribution of commercial scallops and abalone, the localised effects of seismic emissions on the behaviour of benthic invertebrates are not expected to impact areas where these species occur.

The AA has relatively deep waters throughout, where the majority of the water depths of the AA are greater than 700 m. This water depth not only determines what benthic invertebrate species are living within the AA, but it also provides a large separation distance between the acoustic source and the seabed. The typical distances between the acoustic source and the seabed within the OA are far greater than most of the scientific experiments conducted in the literature to assess potential effects of seismic on marine receptors. As such, the residual risk for behavioural impacts to benthic invertebrate species from exposure to acoustic emissions during the Otway Basin 3D MC MSS has been assessed as **Low** (*Minor* x *Unlikely*).

The effects of acoustic surveys on catch rates and fisheries which may manifest as a result of behavioural responses discussed in this section are assessed in **Section 7.2.3**.

7.2.2.3.2 Bony Fish

Behavioural effects of noise on fish will vary depending on the circumstances of the fish, hearing sensitivity, the activities in which it is engaged, its motivation, and the context in which it is exposed to sounds (Hawkins and Popper, 2016). The behavioural responses of fish to acoustic disturbance vary depending on species traits, particularly sensory systems and the presence or absence of a swim bladder (Worchester, 2006; Carroll *et al*., 2017). Species which have swim bladders (or other gas-filled chambers) are considered more sensitive and likely to have a behavioural response to sound exposure compared to species with small or no swim bladders (Popper *et al.,* 2014). Responses may include avoidance behaviours, startle reactions, increased swimming speed, change in orientation, change in position in the water column, changes to schooling behaviour (e.g. tightening of school structure), seeking refuge in reefs, and temporary avoidance of an area (Simmonds and MacLennan, 2005; McCauley *et al*., 2000; Fewtrell and McCauley, 2012; Popper *et al*., 2014; Carroll *et al*., 2017). Changes in movement patterns may also temporarily divert efforts away from feeding, egg production and spawning success (Hawkins and Popper 2016). If observed, studies generally report short-term and localised impacts of acoustic disturbance on fish behaviour, with normal behaviour returning within approximately one hour after the removal of the acoustic source (McCauley *et al*., 2000; Pearson *et al*., 1992; Wardle *et al*., 2001).

Pearson *et al*. (1992) exposed captive rockfish to multiple ten-minute periods of seismic emissions from a seismic acoustic source. Schools of rockfish were observed to exhibit a 'startle' response (shudders, flexions of the body followed by rapid swimming) at sound levels above 200 – 205 dB re 1µPa SPL. An 'alarm' response (change in vertical position in the water column to be closer to the seabed, short-term post-exposure behavioural changes) was found to occur above approximately 180 dB re 1µPa SPL, although it was suggested that some individuals begin to exhibit subtle changes in behaviour and position in the water column at sound levels above 161 dB re 1µPa SPL. Changes in behaviour were found to return to normal before the end of the sound exposure or within minutes of the sound ceasing, indicating only very short-term, transient effects and potential habituation to the disturbance (Pearson *et al*., 1992).

Santulli *et al.* (1999) exposed caged European sea bass (a demersal species) to a 2,500 in^3 acoustic source. Limited response was observed at 2.5 km distance. A startle response was observed when the array was at approximately 800 m, but after passing within 180 m, fish behaviour appeared to return to normal within one hour. Increased biochemical stress levels were measured in some fish following exposure, returning to normal levels within 72 hours of exposure. It is noted that exposures of fish in the wild would likely result in avoidance of high sound levels prior to the acoustic source approaching to as close a range and to as high sound levels as those used in the experiment (Santulli *et al.,* 1999).

Wardle *et al.* (2001) exposed tagged, free-swimming marine fish (i.e. juvenile cod and saithe, adult pollock from the sound pressure-sensitive family Gadidae, and adult mackerel from the relatively insensitive family Scombridae) on an inshore reef to sounds from a seismic source (195 – 218 dB re 1 µPa PK). The authors observed the following responses:

- Fish exhibited a startle response (i.e. momentarily performed "C-turns") to all received levels, but no avoidance behaviour or any other longer lasting effects were observed;
- Fish showed no signs of moving away from the reef;
- Slight changes were recorded to the long-term day-to-night movements of two tagged pollock, particularly when located within 10 m of their normal living positions; and
- Exposure to the seismic noise did not interrupt a diurnal rhythm of fish gathering at dusk and had little effect on the day-to-day behaviour of resident fish.

Sivle *et al*. (2016) undertook a pilot study to explore sound source characteristics and experimental design options for evaluating behavioural reactions in mackerel. The authors exposed caged mackerel to a range of playback sounds at close range (2 – 7 m), including filtered playback of seismic pulses recorded at a distance of 8 km with an SEL of 144 dB re 1 µPa2·s. In most tests, mackerels did not react to the seismic sound stimulus. Minor startle responses were observed from a small number of individuals in schools in 20% of tests. A weak or moderate increase in swimming speed was observed in some individuals in schools in 45% of tests, and a weak change in schooling behaviour was observed in a small number of individuals in schools in 10% of tests. In all cases, reactions lasted for the duration of the exposure and returned to normal as soon as the exposure ceased, indicating that some mackerels may show an awareness of seismic sounds at these levels. However, Sivle *et al*. (2016) noted that mackerel are not sensitive to sound pressure, but to particle acceleration, which is likely a key stimulus in this close-range experiment. Sivle *et al*. (2016) also noted that the sound playback technique used had limitations and was not representative of a real seismic signal, suggesting that future experiments should instead use a real acoustic source to obtain more conclusive results. The observations made by Sivle *et al*. (2016) should be interpreted with caution and may not be representative of mackerels' ability to detect propagating sound pressure signals at long distances (i.e. kilometres) from a real MSS.

McCauley *et al*. (2000, 2003) reported that trials involving captive fishes (of various species) exposed to seismic sound showed a common 'startle' response (C-turns), 'alarm' responses (e.g. swimming faster, darting movements and sudden changes in school structure), or more subtle responses such as moving closer to the seabed or grouping closer together. Subtle responses were suggested to commence when sound levels exceeded approximately 151 dB re 1 µPa2.s SEL (approximately 160 dB re 1 µPa SPL). These minimal reactions are likely to be an indication of awareness and perception of the sound rather than a response that could result in potential impacts. Obvious startle and alarm responses were apparent in trials when received sound levels were in the order of 159 – 172 dB re 1 µPa2.s SEL (approximately 168 – 181 dB re 1 µPa SPL). In situations where a behavioural response was observed, fishes were considered to have resumed normal behaviour within 4 – 31 minutes after cessation of the seismic activity. Startle and alarm responses reduced with time, indicating some habituation to the sound. No statistically clear trends in physiological stress response were observed following exposure (McCauley *et al*., 2000, 2003).

Behavioural observations of two tropical snapper species and another coral reef fish species in field enclosures before, during and after exposure to seismic sound showed that repeated exposure resulted in increasingly less obvious startle responses (Boeger *et al*., 2006). This is consistent with the potential habituation suggested by McCauley *et al*. (2000) and by Fewtrell and McCauley (2012).

McCauley and Salgado Kent (2007) observed the behaviour of goldband snapper in fish traps in the Timor Sea in response to emissions from two towed 3,090 in^3 acoustic sources. Maximum signals reached at the closest trap to each pass-by were 200, 202 and 212 dB re 1 µPa PK-PK (equivalent to approximately 194, 196 and 206 dB re 1 µPa PK). No dramatic behavioural responses of fish to the passing seismic source were observed. Fish generally displayed increased activity immediately after entering a trap presumably as they searched for a way out, with this activity reducing with time. Fish which had been in a trap for some time showed increased activity levels as the operating seismic source approached but were 'quiet' when the array passed at the point of closest approach.

Bruce *et al.* (2018) tagged tiger flathead and two shark species in Australia. Sharks moved freely in and out of the study area and exposed sharks did not show any indication of differences in behaviour or distribution compared with control areas. Minor behavioural effects were observed in exposed tiger flathead in the form of increased swimming speed during exposure and changed daily movement patterns after the survey but showed no significant displacement. Overall, there was little evidence for consistent behavioural responses (Bruce *et al*. 2018).

Paxton *et al.* (2017) observed temperate reef fish in 33 m water depth located 7.9 km from a seismic survey line. The authors observed fish abundance and habitat use during the evening hours for three days prior to a MSS and during the evening of the day when seismic activity occurred. Maximum sound levels were estimated to be in excess of 170 dB re 1 µPa. Despite no clear visual evidence of behavioural responses in fishes during the MSS, Paxton *et al*. (2017) noted a 78% decline in abundance in the evening following the MSS. No further investigations were made to assess when fish abundance returned to pre-exposure levels or how far they may have moved. With limited data, it is not clear from this study if reduced abundance is attributed to the MSS or other natural factors such as tidal influence or food availability; however, the study may indicate a possible avoidance response and change in local abundance and distribution.

Meekan *et al*. (2021) undertook a large-scale experiment that quantified the impacts of exposure of an assemblage of tropical demersal emperors (family Lutjanidae), snappers (family Lethrinidae) and groupers (family Epinephelidae) to a commercial-scale seismic source on the North West Shelf off Western Australia. The hearing category of these types of fish is 'Group II'. Baited remote underwater videos and acoustic tagging were used to measure the behaviour and movement of fishes at high, medium, and low exposure sites, and at control sites. The high, medium, and low exposure sites were located at horizontal distances from the path of the seismic source of approximately 0 – 300 m, 2 – 10 km and 11 km respectively. The maximum modelled SEL values received at the high, medium, and low exposure sites were in the order of 180 – 200 dB re 1 µPa2·s, 130 – 160 dB re 1 µPa2·s and 115 – 125 dB re 1 µPa2·s respectively. There were no short-term (days) or long-term (months) effects of exposure on the composition, abundance, size structure, behaviour, or movement of fishes at any exposure sites (Meekan *et al*. 2021). The acoustic tags found little evidence that fish were displaced by the exposure to the seismic source. Movements of tagged fish occurred over a limited area focused on two or three acoustic receivers, and there was no evidence for the departure of tagged fish after exposure, or on their willingness to feed (Meekan *et al*. 2021). These multiple lines of evidence suggest MSS have little impact on the behaviours of demersal fishes in this environment.

Some other studies looking at the behavioural response of sound pressure-sensitive species, such as whiting, Atlantic cod and herring, have reported changes in vertical position in the water column, potential avoidance responses and short-term changes in distribution. For example, Chapman and Hawkins (1969) observed that the depth distribution of free-ranging whiting changed in response to an intermittently discharging stationary seismic source, resulting in fish being exposed to an estimated SPL of 178 dB re 1 µPa. The fish school responded to the sound by shifting downward and forming a more compact layer at greater depth, although temporary habituation was observed after one hour of continual sound exposure (Chapman and Hawkins, 1969).

Slotte *et al*. (2004) monitored the effects of a 3,090 in^3 seismic array on migrating herring and whiting, mapping their distribution and abundance in relation to the seismic survey lines. There was no significant evidence of immediate, near-field scaring reactions on the horizontal scale, but there was some evidence of fish changing position in the water column, moving closer to the seabed in response to the acoustic emissions. Some short-term changes in distribution were observed; fish consistently remained within the immediate vicinity of the survey area, but in a limited number of measurements there was an indication that fish abundance was lower near to the survey area and increased with distance out to a maximum range of 37 km; however, results were inconsistent and not statistically significant, and clear trends were not observed in all cases. Slotte *et al.* (2004) concluded that it was not possible to determine how much abundance and distribution changes were attributed to the MSS or to the fishes' natural migration patterns, food availability or other natural factors. Herring and whiting were found to be abundant in the survey area again after a pause in seismic acquisition and monitoring of fishes for three to four days, indicating that if any displacement did occur as a result of seismic sound exposure, it was temporary (i.e. less than 3-4 days) (Slotte *et al.,* 2004). In similar studies, Engås *et al*. (1996) and Engås and Løkkeborg (2002) reported on the effects of seismic on Atlantic cod and haddock and found that fish abundance was lower in the survey area compared with areas outside of the survey area. The authors hypothesized this may be the result of an avoidance response. Some differences in abundance were still detectable within the survey area five days after completion of the survey (Engås *et al*., 1996; Engås and Løkkeborg, 2002).

Conversely, Peña *et al*. (2013) described the real-time behaviour of schooling herring to a full-scale 3D MSS. No changes were observed in swimming speed, direction, or school size that could be attributed to a transmitting seismic vessel as it approached from a distance of 27 km to 2 km, over a six-hour period. The unexpected lack of a response to the MSS was interpreted as a combination of a strong motivation for feeding by the fish, a lack of suddenness of the onset of sound, and an increased level of tolerance to seismic pulses (Peña *et al*., 2013).

Laboratory experimental approaches to examining the effects of MSSs on fish behaviour typically involve exposing caged individuals to an acoustic source often at intensities and exposure durations that are unlikely to be encountered in the field (Gray *et al*., 2016). In 2007, Woodside engaged a team of more than 20 specialists in the fields of underwater acoustics, coral reef ecology and reef fish biology to design and execute comprehensive investigations into the impacts of seismic airgun noise on (amongst other things) fish behaviour (Woodside, 2007). Behavioural observations of free-swimming fish showed that at close range, airgun noise emissions appeared to cause prominent, short-term effects on fish behaviour. As the vessel approached, fish ceased normal behaviours and moved downward from the water column towards the seabed. Fish began to feed and behave normally again within 20 minutes after the Seismic Vessel had passed. Once the vessel had travelled beyond a distance of ~1.5 km fish numbers and behaviour had returned to normal baseline levels. For caged fish, agitation levels increased with increasing received sound exposure level for the three holocentrid (squirrel fishes and soldier fishes) species studied but were not detectable for the bluestripe seaperch. Alarm responses were too infrequent to analyse (Woodside, 2007). Sonar observations of free-swimming fish showed that individuals tended to move deeper into the water column on approach of the operating seismic array consistently out to 400 m either side of the survey test line. Within 200 m of the survey test line, fish schools moved to the seabed after passage of the operating seismic array and stayed significantly closer to the seabed out to 63 minutes post-exposure. The overall conclusion from the behavioural seismic acoustic exposure experiments was that there was minimal impact on fish behaviour and that any changes that were observed were short term and unlikely to have caused any significant biological or ecological impacts (Woodside, 2007).

Davidsen *et al*. (2019) investigated the effects of seismic exposure on the physiology and behaviour of captive Atlantic cod and saithe. Experimental sound exposures were 18 – 60 dB above ambient. Fish were held in a large sea cage and exposed over a 3-day period. The cod exhibited reduced heart rates in response to the particle motion component of the sound, indicative of an initial flight response. No behavioural startle response to the airgun was observed, although both cod and saithe changed both swimming depth and horizontal position more frequently during sound exposure. The saithe became more dispersed in response to the elevated sound levels. The fish seemed to habituate both physiologically and behaviourally with repeated exposure. The authors concluded that sound exposures induced over the timeframes used in this study appear unlikely to be associated with long-term alterations in physiology or behaviour (Davidsen *et al*., 2019).

Hubert *et al*. (2020) exposed captive Atlantic cod to one hour of playback of seismic airgun sound pulses with a 10-second shot point interval. Cod were placed in a net pen positioned 7.8 m from the speaker. The mean peak sound pressure and particle acceleration levels. It was estimated that the mean SPL of the ambient conditions in the pen was 113 dB re 1 µPa and the mean sound particle acceleration was 61 dB re 1 nm/s2. Results indicated no strong overall pattern of change in swimming patterns or immediate, short-term behaviours during the exposure, compared to baseline periods without playback. However, several individuals changed the time spent in several behavioural states during the one-hour sound exposure; several individuals spent more time transiting and less time being locally active or inactive. This may be indicative of changes in energy expenditure, which may be relevant if sound exposure occurs over the long-term. However, due to experimental design limitations, it was not possible to test the significance of these behavioural state trends (Hubert *et al*., 2020).

Van der Knaap *et al*. (2020, 2021) investigated the effect of a 3.5-day, full-scale, MSS on the movement behaviour of free-swimming Atlantic cod. The closest point of approach to the location of tagged fish was 2.25 km. The authors found that during the MSS, cod did not leave the detection area more than expected from baseline data. However, cod left more quickly than expected from two days to two weeks after the MSS. Furthermore, behavioural analyses indicated that during the exposure, cod decreased their activity, with less time spent being locally active (moving over small distances, showing high body acceleration), and an increase in time spent being inactive (moving over small distances, having low body acceleration). Additionally, diurnal activity cycles were disrupted with lower locally active peaks at dusk and dawn—periods when cod is known to actively feed.

Fishwell Consulting Pty Ltd (2020) provide preliminary results from a multiple – before after control impact analysis of the effect of a full-scale commercial 3D MSS on Danish Seine catch rates of two continental shelf species (flathead and eastern school whiting) in waters off Lakes Entrance, VIC. The MSS was undertaken in four phases in 2020 and preliminary results are currently published for the first three phases. Overall, the analyses provide robust evidence for a negative impact of seismic acquisition on whiting catch rates in the Danish Seine Fishery up to ~100 days following the MSS and flathead catch rates in the Danish Seine Fishery up to ~200 days following the MSS (see **Section 7.2.3.1**. for more detailed results). The reported long term catch reduction of both species contrasts with most other studies where impacts to fish are typically more short term. However, the apparently statistically significant differences between impact and control sites and the reason for the effects lasting 100 – 200 days are notable. Neither of the species studied belong to families of fish that are regarded as being particularly sensitive to changes in underwater sound pressure; however, the relatively shallow sites where the two benthic species are targeted may have experienced significant changes in particle motion near the seabed or ground-borne vibration in seabed sediments that may have resulted in a greater level of behavioural disturbance than to demersal and pelagic species in other studies. Such seabed conditions are not predicted to occur during the Otway Basin 3D MC MSS given the significantly greater water depths.

Fishwell Consulting Pty Ltd (2020) also presents historical logbook data for the period 2014 – 2019, as well as the 2020 MSS. Logbook data demonstrated that catch levels of both species were already highly variable and in decline prior to the MSS. During and after the 2020 MSS in 2020, catch levels at both impact and control sites were some of the lowest on record since 2014 suggesting that there may be other broader factors involved during 2020.

Based on the above body of literature, the following conclusions can be made regarding behavioural effects to fish from MSSs:

- Different fish may exhibit different behavioural responses when exposed to MSS noise, depending on their activities, motivation and the context in which they receive sound;
- Fish may change position in the water column (i.e. move closer to the seabed) as a response to becoming aware of approaching seismic sound (Pearson *et al*., 1992; McCauley *et al.*, 2000, 2003; Slotte *et al.,* 2004; Fewtrell and McCauley, 2012; Miller and Cripps, 2013; Davidsen *et al*., 2019);
- Exposure to higher sound levels at close range to a seismic source may begin to result in more noticeable startle or alarm responses, such as changes in school structure, increased swimming speed and avoidance of the sound source (Simmonds and MacLennan, 2005; McCauley *et al*., 2000, 2003; Fewtrell and McCauley, 2012; Popper *et al.,* 2014; Carroll *et al.,* 2017);
- Many exposure experiments are undertaken using a single airgun and it is not clear how transferrable the behaviours and received SPL/SEL levels are to a full commercial-sized seismic array, particularly if observed behaviours are in response to particle motion close to the sound source rather than to sound pressure. Furthermore, studies on free-living fishes are likely to differ from those with captive fishes because of the many subtle factors that determine tehri behaviour in a natural setting. When studies are done in tanks/enclosures, the sound fields may be very different from those that fish experience in the wild, especially in terms of the magnitude of particle motion relative to sound pressure (Popper and Hawkins, 2019);
- There is some evidence that fish may tolerate gradual increases in sound levels and habituate to repeated sound exposures (Chapman and Hawkins, 1969; McCauley *et al.,* 2000; Boeger *et al.*, 2006; Fewtrell and McCauley, 2012; Peña *et al*., 2013; Davidsen *et al.,* 2019);
- Many studies indicate that fishes resume normal behaviour shortly after cessation of the acoustic disturbance (within minutes to less than an hour), with no evidence of long-term changes (Wardle *et al*., 2001; Pearson *et al.*, 1992; Santulli *et al.,* 1999; McCauley *et al.,* 2000, 2003; Fewtrell and McCauley, 2012; Miller and Cripps, 2013; Davidsen *et al*., 2019); and
- Meekan *et al.* (2021) found no short-term (days) or longer-term (months) effects of seismic exposure on the behaviour and movement of tropical demersal snapper, emperor, and grouper species off northern Australia.

There is some evidence that changes in distribution may persist for longer than the initial change in behaviour, (i.e. position in the water column, schooling behaviours and swim speeds which may return to normal relatively quickly), but their distribution may not return to normal for hours or days. Changes in distribution of fish has been observed in some studies for approximately five days following sound exposure, although such changes are limited to studies that focused primarily on migrating sound pressure-sensitive types of fish with a swim bladder-ear connection (e.g. Clupeidae, Gadidae). These studies also acknowledge that it is difficult to attribute distribution changes directly to the MSS or if they are due to natural factors (e.g migration patterns, food availability, etc.) (Slotte *et al*., 2004; Engås *et al*., 1996; Engås and Løkkeborg, 2002). It is possible that changes to the behaviour and distribution of some sound-sensitive prey species (e.g. herring and sardines) may have some indirect influence on the distribution of larger predatory fishes during the days following exposure and disturbance.

Small changes in behaviour or disruption to diurnal activities of pressure-sensitive species of fish (Gadidae) with a swim bladder-ear connection may indicate that activities such as feeding and energy expenditure can be affected if exposed long-term (Davidsen *et al*., 2019; Hubert *et al*., 2020; Van der Knaap, 2020, 2021), although these species of fish may also habituate to the sound with repeated exposure (Davidsen *et al*., 2019).

Given the limited convergence in results from the available studies, the subjective nature of many assessments and the context under which fish receive sound, Popper *et al*. (2014) do not define exact sound level thresholds or ranges at which masking and behavioural responses may occur. Instead, Popper *et al.* (2014) uses relative risk criteria ranging from high to low. These criteria do not use specific acoustic thresholds, but instead gauge impacts based on general distances from the noise source: near (within tens of metres), intermediate (within hundreds of metres) and far (within thousands of metres). It is difficult to predict the population impacts due to behavioural response because behaviour is context dependent. Behavioural responses of wild animals to sound are likely to vary by species, size, and age class, animal motivation, and in different contexts. Behaviour may be more strongly related to the circumstances of the animal, the activities in which it is engaged, and the context in which it is exposed to sounds (Peña *et al*., 2013; Hawkins and Popper, 2019).

Demersal fishes present within the OA are likely to belong to the Group I or Group II hearing categories. Popper *et al*. (2014) indicates that the potential for behavioural impacts in these categories is high in the near-field, moderate at intermediate distances and low in the far field. Consistent with this, studies relevant to behavioural responses in demersal species indicate that exposure to a mobile seismic source and resultant changes in behaviour are likely to be limited to durations of minutes or hours, or sometimes days, and are most likely to occur within hundreds of metres of the acoustic source as it passes (Pearson *et al*., 1992; Santulli *et al.,* 1999; McCauley *et al*., 2000, 2003; Fewtrell and McCauley, 2012; Bruce *et al*., 2018; Meekan *et al*., 2021). Therefore, behavioural responses in demersal fishes are likely to be localised and temporary.

Commercially significant species with a depth range that corresponds to the AA are identified in **Table 74**. Many of these species are fished by the SESSF CTS and SHS. Based on available information on these fish stocks, most of these species are considered to have a high level of mixing and genetic connectivity and are considered as single genetic stocks throughout their ranges. Many are also highly fecund, releasing thousands or millions of eggs and/or spawn on multiple occasions and have a depth distribution that lies on the periphery of the AA and are largely based in shallower waters. On this basis, occasional localised and temporary behavioural disturbances are not expected to have a material impact on spawning events or ongoing recruitment of the stocks, noting that natural mortality rate for eggs and inter-annual variability in spawning and recruitment due to natural factors can already be high.

Table 74 Depth Range of Commercially Targeted Fishes in the AA

Species	Depth range
Bigeye Ocean Perch	200 – 700 m
Blue Grenadier	200 – 700 m
Blue-eye Trevalla	200 – 900 m
Gemfish	100 – 800 m
Hapuku	50 – 850 m
Mirror Dory	50 – 600 m
Orange Roughy	700 – 1,400 m
Pink Ling	20 – 1,000 m
Ribaldo	450 – 2,500 m
Silver Warehou	50 – 600 m

The AA overlaps with the Zeehan AMP, which has been recognised as a nursery ground for blue warehou and ocean perch, with concentrations of larvae fish of these species found in the AMP. Spawning is generally a sensitive stage in a fish life cycle (Ciannelli *et al.,* 2015), and disturbance during this period could potentially affect the coming year-class strength (McQueen *et al.,* 2022). De Jong *et al*. (2020) suggests that avoidance behaviour after arrival at a spawning ground could lead to movement away from the spawning ground. The response to a stressor (e.g. acoustic emissions) will depend on a trade-off between the cost of being stressed, and the cost of avoiding the stressor (Schreck *et al*., 2016), therefore if the costs of avoidance are too high, animals may remain and spawn (de Jong *et al.,* 2020). De Jong *et al*. (2020) predicted that pelagic spawners are more likely to avoid noise, while species that spawn on specific spawning grounds may remain. McQueen *et al*. (2022) investigated the behaviour of free-ranging Atlantic cod (*Gadus morhua*) over three consecutive years at a spawning ground using acoustic telemetry and a before-after-control-impact approach with one baseline year and two years with seismic exposure. The authors found no evidence that exposure to seismic sources at received levels up to ~145 dB re 1 μPa^2s SEL (comparable to a full-scale MSS at ~5 – 40 km) caused premature departure of cod from the spawning ground. It was suggested that this lack of a detectable response was due to the tagged cod having a strong affinity to the spawning site (McQueen *et al*., 2022).

Pelagic fishes that potentially occur in the AA include SBT, blue mackerel, and yellowtail kingfish. Small pelagic species including Australian herring and Australian sardine (targeted by the SPF) occur in continental shelf waters, but their core distribution does not generally extend far offshore. Many tuna and mackerel species do not possess a swim bladder, or it is poorly developed (Popper *et al*., 2014), indicating they are sensitive only to the particle motion component of sound at close range to an acoustic source. SBT, however, have swim bladders but have no apparent specialist connection with the inner ear (Bertrand and Josse 2000; Song *et al*., 2006). The lateral line system appears to feature in Scombroidei fishes, again indicating fishes are mainly sensitive to particle motion, but some pressure detection is possible. Popper *et al*., (2014) indicate that the potential for behavioural impacts in fishes that do not possess a swim bladder or where the swim bladder is not directly linked to hearing is high in the near-field (tens of metres), moderate at intermediate distances (hundreds of metres) and low in the far field (thousands of metres). Therefore, the extent and duration of behavioural impacts to large pelagic fishes in the AA is likely to be like those predicted for demersal fishes. In addition, pelagic tunas and mackerels are highly transient and travel distances of hundreds and sometimes thousands of kilometres. Therefore, the transient nature of the acoustic source and the equally transient nature of pelagic fishes means that behavioural avoidance responses and effects on distribution will be incidental, localised and of short duration by comparison. Their high mobility also means that physiological effects such as injury or TTS are very unlikely to occur (see **Section 7.2.2.2.3.3**).

Australian herring and Australian sardines are targeted as prey by larger pelagic species (i.e. fish and marine mammals) and seabirds. Australian sardines possess the connection between a swim bladder and inner ear that makes them sensitive to sound pressure (i.e. Group III fish). Popper *et al.* (2014) indicates that the potential for behavioural impacts in Group III is high in the near-field and intermediate distances (tens or hundreds of metres), and moderate in the far field (thousands of metres). Behavioural avoidance responses by sardines may therefore occur over several kilometres or more. At times when the acoustic source is operating close to the continental shelf break adjacent to where sardines may be present, or when acquiring in the 2D Tie Line AA, some avoidance and change in distribution of schools of sardines may occur. This may have a more far-reaching secondary effect on the distribution of predatory species that target them. However, given the limited overlap with the continental shelf (a few hours of acquisition along a 2D tie line) and a limited number of lines that will be acquired along the shallower northern and eastern boundaries of the AA, these impacts will be of limited frequency and duration.

SBT are an important apex predator in the SEMR and are a commercially targeted species. Juveniles migrate to continental shelf waters off southern Australia during the summer months (December to April) where those age approximately 2 – 5 years (14 – 25 kg) are caught by the SBTF (Purse Seine Sub-fishery) (Bulman *et al*., 2020). Juveniles move from spawning grounds (in the Indian Ocean between northern WA and Java) within a few months of hatching, most likely utilising the Leeuwin Current to help them reach the waters of the GAB around where they stay in coastal and continental shelf waters through summer and move away into deeper oceanic waters during winter (Bulman *et al*., 2020). As juveniles, a large proportion of the SBT's diet consists of fish (including sardines), squid and krill (Ward *et al*., 2006; Basson *et al.*, 2012). Previous studies into the high levels of chlorophyll-α as a direct result of upwelling mechanisms, coupled with the strong lateral current systems, has been shown to be a direct precursor to krill swarm formation. This in turn promotes the congregation of sardines feeding on the krill, thus providing rich feeding grounds for juvenile SBT near coastal upwellings such as the GAB and Kangaroo Island upwelling systems (Ward *et al*., 2006).

Popper *et al*. (2014) indicates that the potential for behavioural impacts in fishes such as SBT, where the swim bladder is not directly linked to hearing is high in the near-field (tens of metres), moderate at intermediate distances (hundreds of metres) and low in the far field (thousands of metres). Based on this information, it is possible that SBT may be able to detect seismic sound and minor behavioural responses may commence when the source is within several kilometres, and reactions may become stronger as the source gets closer (hundreds of metres from the source). Whether SBT react to seismic sound over distances of kilometres will depend to some degree on their behaviours and situational context at the time (Popper *et al.*, 2014) such as their motivation to feed; if feeding as a school, local flow noise within the group is likely to mask seismic impulses except potential detection of particle motion components at very close range.

Noting that a key target prey species of SBT is Australian sardine (*Sardinops sagax*), a Group III fish with the ability to detect sound pressure, sardines are likely to exhibit a behavioural response and avoidance of the seismic source over greater distances than SBT (i.e. several kilometres). Therefore, the active acoustic source is more likely to disturb schools of prey than it is SBT, with the resultant localised change in distribution of sardine schools resulting in SBT looking for prey and feeding in areas further from the acoustic source than they would do otherwise.

SBT hearing capabilities are not sensitive to sound at long range and their hearing mechanisms are likely to only detect high sound pressures and particle motions at close range to the source. Based on the review of literature above, it is likely that SBT may respond to seismic impulses at ranges of hundreds of metres (Song *et al*., 2006; Popper *et al.,* 2014). This is supported by observations made during the TGS Nerites Phase 1 MSS in the GAB in 2014 where schools of tens or hundreds of SBT were observed within several hundred metres of an operating 4,100 in^3 acoustic source, displaying normal swimming and feeding behaviour at the surface, indicating limited or no long-range avoidance or change in behaviours. Flow noise and water motion produced by fast moving and closely spaced SBT during feeding likely mask both sound pressure and particle motion components, except very loud noise at close range.

During consultation, fishery representatives expressed concern on the effect of MSSs on the migration of juvenile SBT in southern Australia. Juvenile SBT move from the spawning ground in the north-east Indian Ocean in their first year of life and move southwards along the Western Australia, coast. Surface-schooling juveniles are found in the continental-shelf region of southern Australia through summer and move away into deeper oceanic waters during winter (Bulman *et al*., 2020). Current evidence suggests that most juveniles return to the GAB in the austral summer, but there is some uncertainty about the proportion that returns (Basson *et al*., 2012). Tagging studies have shown that most migration into the GAB occurs in November and December, but arrivals begin in October and continue as late as January (Basson *et al*., 2012; Evans *et al.,* 2017). Departure from the GAB typically occurs from April/May but can begin from February and can continue until July/August (Basson *et al*., 2012). The majority of juvenile SBT migrate west to the Indian Ocean for winter, a much lesser percentage migrate east to the Tasman Sea, while some overwinter offshore from South Australia (Basson *et al.,* 2012). After about five years of age, SBT are seldom found in nearshore surface areas, and their distribution extends over the southern circumpolar area throughout the Pacific, Indian and Atlantic Oceans (CCSBT, 2009).

Changes in the spatial distribution of SBT in the GAB have been observed during the fishing seasons of the last ~10 years. In the 2012 season, movement of SBT through the GAB was rapid, and fish were distributed further east than usual, resulting in less than 15% of purse-seine catches being taken from fishing grounds used in the previous 20 years (Eveson *et al.*, 2014). Similarly, based on aerial survey data from 2003 – 2013, Basson and Farley (2014) report on a more easterly shift in SBT distribution from waters north-west of Port Lincoln to a more spread-out distribution towards waters west of Kangaroo Island. In subsequent years, ABARES fishing effort data suggests that fish are distributed into the far eastern GAB, with purse seine catches in some years being taken in shelf waters to the west and south of Kangaroo Island. Fishery stakeholders suggested that the eastward shift in SBT distribution is becoming more common. Recent fishing effort indicates that the AA lies outside of the main distribution of surface schooling juveniles during the summer residency period in the GAB. Given the location of the Otway Basin 3D MC MSS (i.e. offshore and further towards TAS than the main distribution areas), it is not expected to present a barrier to migration of young (1-year-old) juvenile SBT into the GAB from the Indian Ocean. The majority of 2 – 5-year-old juvenile SBT also depart the region in a westerly direction towards the Indian Ocean and sound from the Otway Basin 3D MC MSS would not present a barrier to this migration.

The smaller proportion of SBT juveniles that migrate east towards the Tasman Sea or south into deeper waters offshore from South Australia have the potential to be disturbed. However, given the transient nature of the acoustic source and the equally transient nature of SBT, localised behavioural avoidance responses and effects on distribution will be incidental, localised and of short duration by comparison. For example, Basson *et al*. (2012) estimated from tagged SBT that, on average, SBT may travel between 100 and 200 km per day or more during migration and up to 70 km per day when resident. Behavioural disturbance and changes in distribution (potentially ranging from hundreds of metres to several kilometres from the acoustic source, depending on direct disturbance or secondary effects due to changes in the distribution of prey species) are relatively small by comparison.

Evans *et al*. (2017) identified that the timing of past geophysical surveys within the GAB have overlapped the spatial and temporal occurrence of juvenile SBT. The direct measurement of spatial overlap had inherent errors estimating the position of juvenile SBT at exact times. The authors concluded that "*while some parameters could be identified as influencing the behaviour of juvenile SBT, which ones, and the strength and direction of the relationships, varied temporally and across individuals. This made identifying clear relationships between behaviour and environmental parameters difficult, suggesting that the drivers for behaviour of juvenile SBT are complex, and potentially interdependent and covarying in nature*". Further, the authors did observe that during geophysical surveys, at a broadscale, tagged juvenile SBT individuals remained in the GAB during survey periods and for individuals where observations are available across multiple years, the individuals continued to migrate to the GAB over the austral summer period.

Further, catch history reported by the SBTF purse seine sub-fishery in the GAB and the long line sub fishery active in the Tasman Sea, are indicative of approximately 4,000 to 5,000 tonnes of SBT consistently being caught by the purse seine sub-fishery each year each year, as well as increasing quotas for the fishery and increasing catch rates in the east coast long line sub-fishery, despite MSSs occurring in the region during the SBT season in some years, including in consecutive years in 2014 and 2015, and two 3D MSSs occurring concurrently in the central GAB in 2015. Increasing catch levels on the east coast relates to increased Total Allowable Catch for the SBTF (with an apparent corresponding relative reduction in the percentage of TAC from the purse seine sub-fishery), but numbers suggest that SBT continue to migrate to the Tasman Sea where they are caught by the fishery and continue to migrate back to the GAB each summer. Although these numbers present a simplistic account of the situation, there is no pattern that would suggest numbers of SBT are reducing significantly off southern Australia or the Tasman Sea, or that MSSs are preventing or changing the migration of juvenile SBT.

Summary

Overall, the effects on fish from acoustic emissions during the Otway Basin 3D MC MSS will mainly be behavioural. If observed, studies generally report short-term and localised impacts of acoustic disturbance on fish behaviour, with normal behaviour returning within approximately one hour after the removal of the acoustic source (McCauley *et al*., 2000; Pearson *et al*., 1992; Wardle *et al*., 2001). Behavioural changes resulting from exposure to acoustic disturbance have been reported to include startle responses (Pearson *et al*., 1992; Wardle *et al*., 2001; Hassel *et al*., 2004; Boeger *et al*., 2006); modification in schooling patterns and swimming speeds (Pearson *et al*., 1992; McCauley *et al*., 2000; Fewtrell and McCauley, 2012); freezing (Sverdrup *et al*., 1994); and changes in vertical distribution in the water column (Pearson *et al*., 1992; Fewtrell and McCauley, 2012). Evidence of habituation through a decrease in the degree of startle response following multiple exposure events (Hassel *et al*., 2004) suggests responses may be associated with predator avoidance behaviour (Skaret *et al*., 2005) particularly for naïve fish.

Most demersal and pelagic fish species present on the continental shelf, slope and deep waters are not sensitive Group III fishes; they are likely to belong to the Group I or Group II hearing categories. As such, they are not sensitive to sound pressure and are primarily sensitive to the particle motion components of seismic discharges at relatively close range. The potential for behavioural impacts in these categories of fishes is high in the near-field (tens of metres), moderate at intermediate distances (hundreds of metres) and low in the far field (thousands of metres).

SBT are not sensitive to sound pressure. Sight and smell are expected to play more of a role in the location and tracking of prey. Behavioural effects are likely to be limited to within hundreds of metres of the acoustic source, with low likelihood of behavioural effects over distances of kilometres. The limited sensitivity of SBT to sound and review of steady catch and quota history in the GAB and Tasman Sea sub-fisheries of the SBTF relative to historical MSS off southern Australia suggest that it is highly unlikely that MSSs are preventing or changing the migrations of juvenile SBT.

Australian sardines in continental shelf waters are recognised as a Group III hearing fish with the ability to detect sound pressure. Sardines may exhibit a behavioural response and avoidance of the acoustic source over greater distances than SBT (i.e. several kilometres). Therefore, the active acoustic source is more likely to disturb schools of prey than it is SBT, with the resultant localised change in distribution of sardine schools resulting in SBT looking for prey and feeding in areas further from the acoustic source than they would do otherwise. These potential flow-on effects to marine food webs are expected to be spatially restricted to within a few kilometres of the Seismic Vessel with baseline conditions resuming relatively quickly after the survey line is complete (Richardson *et al*., 2017). The energetic consequences of a small shift in foraging habitat will likely be negligible for pelagic fish.

It is considered that the consequence of seismic emissions on fish behaviour within the OA is negligible; with no predicted adverse effect to populations expected and recovery from any impact is expected to occur. As such, the residual risk of impacts to fish behaviour based on exposure to acoustic emissions associated with the Otway Basin 3D MC MSS has been assessed as **Low** (Minor *x Unlikely*).

7.2.2.3.3 Elasmobranchs

Elasmobranchs detect sound via particle motion and some of the highest sound sensitivity to low frequency sound (~20 Hz to ~1,500 Hz) (Myrberg, 2001; Casper *et al*., 2012), which is the largest proportion of sound frequency that is generated during an MSS (Carroll *et al*., 2017). Due to their lack of swim bladder, sharks are considered to fall into the Group I hearing group. Popper *et al*. (2014) indicates that the potential for behavioural impacts in Group I fishes is high in the near-field (tens of metres), moderate at intermediate distances (hundreds of metres) and low in the far field (thousands of metres).

Many species of shark are predatory and use their 'hearing' to locate prey. Therefore, any interruptions to their ability to find/detect food through excessive noise in the environment could impact on the sharks feeding ability (Popper, 2003).

Klimley and Myrberg (1979) found that sharks would withdraw from high intensity sound source that was more than 20 dB re 1 µPa above broadband ambient SPL once within 10 m of the source location. As part of the Gippsland Marine Environmental Monitoring Project, Przeslawski *et al*. (2018a, 2018b) and Bruce *et al*. (2018) found that seismic operations resulted in no evidence of consistent adverse effects on commercial catch rates of sharks, with some species (i.e. elephant fish, broadnose and school sharks) having increased catch rates following the MSS, while others (i.e. gummy shark and saw shark) showed decreased catch rates.

Shark species are highly vagrant and naturally cover large distances, and as such, short-term exposures from the transient acoustic source is expected to result in only localised behavioural responses and movements of sharks. Bruce *et al.* (2018) tagged two commercially targeted shark species (including school shark) and monitored their movements in response to a MSS in Australian waters. The authors noted that both control sharks and exposed sharks moved freely in and out of the study area which did not indicate any changes in behaviour or distribution as a result of seismic exposure (Bruce *et al.,* 2018).

There are four species of threatened and/or migratory species of elasmobranch that have been identified within the EPBC Act Protected Matters Report as potentially present within the OA (see **Section 4.5.3.3**). These species are all considered to be wide-ranging and, with the exception of the white shark, there are no areas of particular biological significance to elasmobranchs within the OA. The OA overlaps with distribution BIAs for white sharks, although density of white sharks within these areas is expected to be low.

Little gulper sharks and school sharks are listed as 'conservation dependant' species protected from overfishing. Little gulper sharks are restricted to the upper continental slope, typically in water depths between ~200 m and 700 m (Last and Stevens, 2009). Tagging found little gulper sharks have a home range up to 50 nm and move freely between the shallow and deeper margins of their distribution (Williams *et al*., 2012). School sharks are a temperate demersal species found on the continental shelf and slope that can be found to depths of 550 metres.

The residual risk of behavioural impacts to elasmobranchs from acoustic emissions during the Otway Basin 3D MC MSS has been assessed as **Low** (*Minor* x *Unlikely*) with no impacts to populations due to behavioural changes expected.

7.2.2.3.4 Cephalopods

Studies have shown that seismic sounds can elicit a behavioural response in cephalopods. Fewtrell and McCauley (2012) described behavioural responses of squid (*Sepioteuthis australis*) such as a startle (squid inking) and avoidance response at a sound exposure level of 162 dB re 1µPa^2.s and an increase in swimming speeds at levels above 147 dB re re 1µPa^2. s. Aggressive behaviours were also brought about following exposure to the acoustic stimulus. The study reports on responses relative to SEL. No assessment of particle motion is provided so scaling up of the experiment to a commercial scale MSS may not necessarily induce the same responses at the same SELs and responses may be limited to close proximity of the source. The SELs reported by Fewtrell and McCauley (2012) have been used in the UAM report (Welch *et al*., 2023) as the noise threshold for squid/octopus startle (inking) response. UAM results (Welch *et al.,* 2023) indicate that a behavioural response (i.e inking startle response) may occur in cephalopods at distances of 1 – 2.4 km from the acoustic source.

Caged cephalopods that were exposed to acoustic sources demonstrated a startle response above 151 – 161 dB re 1 µPa and tended to avoid acoustic disturbance by exhibiting surface behaviours (McCauley *et al*., 2000). During this study it was found that the use of soft-starts effectively decreased the startle response. TGS will be operating in accordance with the EPBC Act and will be undertaking soft-starts on activation of the acoustic source.

Fewtrell (2003) looked at the response of southern calamari squid (*Sepioteuthis australis*) to MSS noise, finding avoidance behaviours once noise levels exceeded 158 dB re 1 µPa, and significant increases in alarm responses with noise exceeding 158–163 dB re 1 µPa. There was a decrease in the frequency of alarm response for repeated exposures, perhaps suggesting that they became habituated (Fewtrell, 2003). Fewtrell and McCauley (2012) also noted that squid showed fewer alarm responses with subsequent exposure to the acoustic source, suggesting either habituation or impaired hearing. Samson *et al*. (2014) found that cuttlefish became habituated to repeated 200 Hz pips at 150 dB and 165 dB, and Mooney *et al*. (2016) found that squid became habituated during sound exposure trials using 140 – 165 dB. McCauley *et al*. (2000) suggested that thresholds affecting squid behaviour occur at 161 – 166 dB re 1 µPa rms.

Fewtrell (2003) found that feeding squid ate immediately after noise exposure, suggesting rapid recovery, where it was noted that food appears to be a powerful stimulus to these animals – "*….The presence of food in an area could override the stimulus to leave an area affected by seismic survey noise*". This is supported by McCauley *et al*. (2000a), who found that captive squid strongly associated the service dinghy with feeding, to the point where squid approached the dinghy to be fed immediately after the cessation of acoustic noise operations (from the same location). McCauley *et al*. (2000a) also found that cephalopods moved to the water surface during MSS simulation and given sound exposure is lower at the surface due to the 'Lloyd Mirror Effect' this could indicate avoidance behaviour to the sound.

In a literature review on the effects of acoustic noise from MSSs, Carroll *et al.* (2017) categorised studies into the presence or absence of a response from cephalopods depending on the level of exposure (**Table 68**). Carroll *et al*. (2017) found four studies where cephalopods exhibited a startle response to realistic MSS noise. These included Fewtrell and McCauley (2012), McCauley *et al*. (2000a), Samson *et al*. (2014), and Mooney *et al*. (2016). Carroll *et al*. (2017) included a fifth study in this list, Komak *et al*. (2005), where juvenile cuttlefish were exposed to local sinusoidal water movements of different frequencies (0.01 – 1,000 Hz) produced by a vibrating sphere placed 5 mm above their heads. This resulted in a startle response with no evidence of habituation, but the methods are not realistic or comparable to an MSS under the Carroll *et al*. (2017) definition.

Given their pelagic lifestyle, there is the potential for squid and cuttlefish to come near the acoustic source during the Otway Basin 3D MC MSS. However, squid are generally short-lived, fast growing species with high fecundity rates. These life history traits mean they are well adapted to disturbance. Furthermore, none of the cephalopod species recorded in the OA are included in the EPBC Act List of Threatened Fauna.

UAM results (Welch *et al.,* 2023) indicate that a behavioural response (i.e inking startle response) may occur in cephalopods at distances of 1 – 2.4 km from the acoustic source. A typical behavioural response to an acoustic source is likely to include being startled (McCauley *et al*., 2000); however, studies have shown that squid quickly become habituated (Fewtrell and McCauley, 2012), and this behavioural disturbance does not appear to influence feeding (McCauley *et al*., 2000a). The life history traits of cephalopods mean they are well adapted to disturbance and combined with the above findings that they appear to become habituated to acoustic release and display other behaviour that indicates rapid recovery, suggests that there is no anticipated long-term risk to populations presented by the Otway Basin 3D MC MSS. Consequently, the residual risk of behavioural impacts to cephalopod species from acoustic emissions during the Otway Basin 3D MC MSS has been assessed as **Low** (*Minor* x *Unlikely*).

7.2.2.3.5 Marine Reptiles

As described in **Section 4.5.5**, there are three species of threatened marine turtle that are known, likely, or may be present in the OA. Only leatherback turtles typically have a temperate distribution and are regularly seen in TAS and VIC waters during the summer months, although sightings are mainly of foraging individuals in coastal and continental shelf waters, not deep offshore waters such as those of the OA. The primary pathway for behavioural effects to marine turtles during the Otway Basin 3D MC MSS is considered to be through alterations to at-sea foraging behaviours.

Compared to cetaceans and fish, research on the impacts of underwater noise on turtles is scarce. Lenhardt (1994) found that loggerhead turtles managed to minimise exposure to seismic simulations in a confined environment by swimming to and remaining at the water surface. Also, in a confined environment, McCauley *et al*. (2000a) observed an alarm response (rapid swimming) in caged loggerhead and green turtles when acoustic source levels exceeded 166 dB re 1 µPa rms. Swimming behaviour was described as more erratic once acoustic source levels reached 175 dB re 1 µPa rms (McCauley *et al.*, 2000a) and this level has subsequently been adopted as the ‘behavioural disturbance’ threshold.

As Nelms *et al*. (2016) points out, studies carried out within the confines of a cage or tank are biased by the acoustic properties of the immediate environment, and results may differ in an open ocean environment where behaviour may change because turtles are able to swim away from the acoustic source. Observations of turtle behaviour at sea are difficult because they require calm sea conditions, and it is often difficult to distinguish behavioural response from variables other than the acoustic source sounds, such as the presence of the Seismic Vessel, the towed equipment, and the observation vessel. Nelms *et al*. (2016) also raises the issue of subjective and variable interpretation of turtle behaviour by different observers, giving the example of one study reporting "*no signs of panic of distress*" during a seismic survey, where behaviour consisted of either 'steady swimming' or 'diving' to avoid the vessel, whereas similar studies categorised diving as a startle response or avoidance behaviour (Nelms *et al*., 2016).

The UAM (Welch *et al.,* 2023) indicates that sound pressure levels >166 dB re 1µPa and >175 dB re 1µPa are not detected at any horizontal distances greater than 4.18 km and 1.37 km, respectively (**Table 75**). These are maximum over depth ranges, therefore the ranges in the upper water column where marine turtles may be present will likely be significantly less. As turtles spend substantial periods of time at or near the sea surface, exposure may be avoided to some degree if their heads are out of the water or moderated by the Lloyd Mirror Effect (Carey, 2009). This effect is produced by destructive interference between the direct path of a low-frequency sound and the sea surface reflection of that sound, and results in an area of acoustic shadowing where the sound is attenuated (much quieter) or cancelled in the top 0.5 - 2 m of the water column (Gerstein, 2002 as cited in O'Shea and Poche, 2006).

Table 75 Behavioural Threshold Levels for Individual Marine Turtles – Impulsive Noise Events

Threshold	Zones of impact – maximum horizontal distance from source to impact threshold levels	
	Criteria – RMS SPL (dB re 1µPa)	Maximum threshold distance (km)
Behavioural response	166	4.18
Behavioural disturbance	175	1.37

Impacts associated with anthropogenic activities, such as acoustic disturbance, are considered in the Recovery Plan for Marine Turtles in Australia 2017 – 2027 (Commonwealth of Australia, 2017a). Whereby, '*Management of anthropogenic activities in Biologically Important Areas to ensure that biologically important behaviour can continue'* is a requirement under this report. The OA does not overlap with any marine turtle BIA. The OA is therefore not considered to be particularly important to marine turtles.

The JASCO UAM (2023) modelling outputs indicate that some behavioural effects to marine turtles within the OA, however, this area does not represent important habitat and marine turtles are not expected to occur in the OA in high numbers. Furthermore, due to the transitory nature of the active acoustic source, whereby at a speed of 4.5 knots the Seismic Vessel will travel up to 200 km in 24 hours, any effects are expected to be minor, short-term and affect a small number of individuals likely to be present within the OA. A 100 m precautionary Shut-down Zone from the operating source will be applied to marine turtles. The acoustic source will be shut-down, or start-up will be delayed for 15 minutes if a marine turtle is observed within the 100 m Shut-down Zone. Operation of the acoustic source using soft-starts may only resume when the turtle has been observed to move outside the 100 m Shut-down Zone, or when 15 minutes have lapsed since the last turtle sighting.

Based on the available evidence, and the low numbers of marine turtles expected to occur within the OA, the residual risk of behavioural impacts to marine turtle species from underwater noise exposure during the Otway Basin 3D MC MSS has been assessed as **Negligible** (*Negligible* x *Rare*).

7.2.2.3.6 Marine Mammals

Vessel noise has the potential to disrupt the behaviours of marine mammals, but it is challenging to dissociate the effects of shipping noise from those of the physical presence of the vessel in eliciting a behavioural response (Aguilar Soto *et al*., 2006). While behavioural responses to vessels have been observed in numerous species (for reviews see Senigaglia *et al*., 2016; Machernis *et al*., 2018); it is only recently that vessel noise has specifically been identified as a driver of such responses (e.g. Sprogis *et al*., 2020; Martin *et al*., 2022). Several studies that assess behavioural changes in response to vessel noise are discussed below indicating that responses to vessel noise vary with species and context.

Evidence of behavioural responses in humpback whales to increasing vessel noise were reported by Blair *et al.* (2016), where significant effects on foraging (such as a reduction in the number of bottom-feeding events per dive, slower descent rate and fewer side-roll feeding events per dive) corresponded with increasing ship noise and led to an overall reduction in foraging rate and efficiency. Although humpback whales showed some habituation towards vessel noise, they were unable to completely adjust to the disturbance (Blair *et al.,* 2016). Dyndo *et al*. (2015) experimentally exposed captive harbour porpoises to vessel noise and reported a high level of disturbance (porpoising away) to low levels of vessel noise.

Disturbance from vessel noise has recently been demonstrated to reduce foraging time for endangered killer whales in the Salish Sea (DFO, 2017). In response to this finding, voluntary speed reductions were trialled whereby vessel speed reductions of 2.1 – 7.7 knots (for general cargo ships and container ships respectively) resulted in noise level reductions of 5.9 – 11.5 dB, and subsequent increases in foraging time for killer whales (11.5%) (Vancouver Fraser Port Authority, 2018). This clearly demonstrates that reducing vessel speed is an effective way of reducing the underwater noise generated at the vessel source.

Nowacek *et al*., (2007) investigated the behavioural response of northern right whales following the controlled exposure of whales to various recorded sounds. While individuals reacted strongly to an alert signal, and mildly to conspecific sounds, no behavioural response was observed for vessel noise. A lack of measurable response was also found when whales were approached by a vessel (Nowacek *et al*., 2007). Similarly, no response was reported for bowhead whales in the vicinity (8-50 km) of ships in the Pacific Arctic (Martin *et al.,* 2023).

Marine mammals exhibit varying behavioural responses to underwater noise (e.g. momentary pauses in vocalisations and changes in body orientation, to changes in travel direction and behavioural avoidance) to received SPLs of 140 and 180 dB re 1 µPa and as low as 110 dB re 1 µPa in some instances (Southall *et al.* 2007; Gomez *et al*. 2016). Reported behavioural effects specifically from seismic surveys include avoidance or displacement, and changes in swimming or diving behaviour (Gordon *et al*., 2003; Miller *et al*., 2009) both of which have the potential to lead to significant reductions in sightings rates across large areas of marine ecosystem (Kavanagh *et al*., 2019). If such effects persist over prolonged periods, they have the potential to significantly increase energy expenditure, decrease foraging efficiency, disrupt group dynamics (e.g. group cohesiveness), and lower reproductive rates (Weilgart, 2007; 2013); however, such effects may also be of limited ecological consequence if they are strictly temporary (Weilgart, 2007).

Studying the behavioural effects of a MSS on marine mammals can be difficult as reactions vary depending on factors such as the species, individual, age, sex, prior experience with noise, and behavioural state (Weilgart, 2007), with studies typically focusing on opportunistic observations of surface behaviours (Verfuss *et al*., 2018). In addition, behavioural responses may be subtle and barely detectable, with the potential to incorrectly suggest an apparent tolerance (Weilgart, 2007). In open seas it is unlikely that temporary displacement would have significant energetic consequences for migrating whales, but displacement could have more significant consequences in confined waterways or for resident populations.

It has been hypothesised that an increase in surface behaviours reduces an individual's exposure to high levels of underwater noise. During such responses, animals take advantage of the 'Lloyd mirror effect' (Carey, 2009) which significantly reduces sound intensity in the upper-most part of the water column. This effect is produced by destructive interference between the direct path of a sound and the sea surface reflection of that sound, and results in an area of acoustic shadowing where the sound is attenuated (much quieter) or cancelled in the top 0.5 - 2 m of the water column (Gerstein, 2002 as cited in O'Shea and Poche, 2006).

An RMS SPL of 160 dB re 1 µPa has been identified as the level at which adverse behavioural disturbance could occur (NOAA, 2019). However, behavioural changes have been noted for some species at noise levels below this threshold. For instance, behavioural changes were observed for bowhead whales at received levels as low as 125 dB re 1 µPa (Richardson *et al*., 1995), and in other circumstances higher noise levels elicit no significant behavioural response (e.g. Moulton and Miller, 2005). The context of sound exposure plays a critical and complex role in behavioural responses in marine mammals (Gomez *et al.* 2016). For example, different species (and different individuals or groups within a species) may respond differently to varying levels of sound depending on their behaviours and motivation at the time (e.g. foraging, socialising, resting and reproduction) and other factors such as the type of sound, duration of exposure, and the suddenness of the onset of the received sound (Gomez *et al*. 2016). Currently, there are no specific received level thresholds for reliably assessing or regulating stress responses. Impact assessment is primarily focussed on responses that may impact survival, lead to significant life stage impacts or displacement from biologically important areas, so a threshold for behavioural disturbance based on cetacean avoidance reactions to seismic is more commonly adopted as a proxy for such effects (Gomez *et al*. 2016). Examples of behavioural responses to seismic survey noise are provided in the following paragraphs.

Humpback whales demonstrate variable responses to seismic noise. Malme *et al*. (1985) reported feeding humpback whales responded to levels of 150–169 dB re. 1 µPa, similarly, McCauley *et al.* (1998) observed that migrating and feeding humpback whales showed behavioural responses at SPLs of 150 – 170 dB re 1µPa. Aerial observations of migrating humpback whales off Australia's east coast were made by McCauley *et al*. (2000) before, during, and after a 3D MSS. Sightings rates were considerably higher around the seismic vessel when the source was inactive compared to operational periods, suggesting active avoidance during seismic acquisition. Transiting whales consistently undertook avoidance manoeuvres (altered course and speed) at >4 km to pass no closer than 3 km behind an operating seismic vessel, while those engaged in sedentary behaviour avoided the operating vessel at a range of 7 – 12 km (McCauley *et al*., 2000). Approach trials were also carried out using a single operating acoustic source. The mean SEL to elicit avoidance behaviour was 140 dB re 1 µPa SPL and startle responses were observed at 112 dB re 1 µ Pa SPL (McCauley *et al*., 2000). Individual whales were also observed spending extended periods in surface waters when acquisition was underway (McCauley *et al*., 2000). McCauley *et al*. (2000, 2003) note that some resting female humpback whales with calves display avoidance reactions at approximately 140 dB re 1 µPa SPL, though other cohorts reacted at higher levels (157–164 dB re 1 µPa SPL) and some males were even attracted towards the seismic source at received levels up to 179 dB re 1 µPa SPL.

While some avoidance responses of migrating humpback whales were also reported by Dunlop *et al.* (2016) off Australia's east coast, Dunlop *et al.* (2015) reported little or no behavioural response to underwater seismic noise; however the received levels in this study were low (close to background levels up to 156 dB re 1 µPa), hence they may not have been high enough to elicit a detectable response (Dunlop *et al*., 2015). McCauley *et al*. (2000) hypothesised that actively migrating humpback whales are less sensitive to seismic survey noise and were at a low risk of ecologically meaningful disturbance. Conversely, whales engaging in resting behaviours at key habitats (e.g. resting grounds), and cow-calf pairs were particularly sensitive to disturbance from underwater noise (McCauley *et al*., 2000). On this basis, the context of exposure is important as animals engaged in certain behaviours may be at greater risk of disturbance than others (Gomez *et al*., 2016).

Further quantification of migrating humpback whale response to seismic survey noise was undertaken by Dunlop *et al.,* (2017) who focussed on changes to dive times, respiration rates, surface behaviours, and group movements. During this study 'typical' behaviours (such as singing, surface slapping, conspecific socialising and southward migratory travel) continued, suggesting that survey noise had little impact on typical behaviours and there was no evidence the whales were under significant additional stress. While some minor and temporary behavioural changes were observed, these were within the normal behavioural repertoire of migrating groups. Most noteworthy was that migratory progress was slower when whales were exposed to survey noise, although this reflected deviance from course as opposed to reduction in swimming speed. The reported deviations were typically short term and localised. The average deviation from the operating sound source was approximately 500 m, only 100 m (±75 m) further from the sound source than when whales were observed avoiding the vessel without the seismic source operating (Dunlop et al., 2017; Gisiner, 2017). Maximum deviations were 1,500 m to 1,800 m; however, this larger deviation involved the group of whales approaching the source (potentially out of curiosity), not avoiding it, and therefore, a reported change in movement behaviour did not necessarily result in avoidance of the source (Dunlop *et al.*, 2017; Gisiner, 2017). Such small and inconsistent deviations are generally insignificant within the larger context of a migration that occurs over months and thousands of kilometres (Gisiner, 2017). Dunlop *et al.* (2017) also noted that migrating whales are only likely to be exposed to a seismic survey for a short period of time before moving away as part of their migration. Dunlop *et al.* (2017) observed that changes in movement behaviour are likely to occur within 4 km from the Seismic Vessel at received levels over 135 dB re 1 µPa. Clear course changes of migrating humpback whales were observed by Dunlop *et al.* (2017) at received levels of 144 – 151 dB re 1 µPa.

The sensitivity of blue whales to seismic surveys remains somewhat unclear, but Gordon *et al.* (2003) suggests that blue whales may be more sensitive to seismic surveys than other baleen whales. This hypothesis is based on the response of a single tagged whale in the vicinity of active seismic operations as reported by McDonald *et al.* (1995) to describe a long-range avoidance response. In this instance, data from an array of seismometers mounted on the seafloor was analysed during a seismic survey (using a source array with a total capacity of 1,600 cui and a source level of 215 dB PK-PK over a 10- 60 Hz band). This study detailed the whale starting its call sequence when the survey vessel was 15 km distant. As the whale approached it stopped calling at a range of 10 km from the survey vessel. The received sound level at the whale's closest position was 143 dB PK-PK. After a gap in the call sequence, a new call series was located 10 km from the ship, suggesting it had tracked parallel to the ship and then moving diagonally away whereby the whale's track altered by c. 120° from its original course (McDonald *et al.*, 1995). Morrice *et al.*, (2004) (as cited in APPEA, 2013) undertook a series of aerial surveys in conjunction with a seismic survey along the shelf and shelf-break areas of Port Lincoln and Kangaroo Island in December 2003. Throughout this project 152 sightings of PBWs were made over a total survey area of 5,700 NM. Many observations of feeding behaviour were made, and, at their closest point, PBWs were reported within approximately 2.4 km of the active seismic source. Cow and calf pairs, which are considered the most sensitive of whale aggregations, were recorded within 7.1 km. Morrice *et al.* (2004) stress that the proximity of whales to seismic operations must be interpreted in the context of their pressing need to consume tonnes of food per day, i.e. PBWs may need to feed into their zone of acoustic discomfort if the only krill available is in proximity to a seismic vessel.

Avoidance behaviours of minke, sei and fin whales have also been reported by Stone (2003) who analysed cetacean sighting reports from Seismic Vessels in UK waters between 1998 – 2003. This analysis revealed that ranges of minke, sei and fin whales to seismic operations were significantly greater for sightings made during active acquisition than at other times. Avoidance behaviours have also been reported for fin whales by Castellote *et al.* (2012) who observed substantial displacement from an active seismic source which persisted well beyond the duration of the survey.

Reported behavioural responses of sperm whales to seismic surveys are variable. Mate *et al*. (1994) observed a significant decrease in sperm whale abundance in the Gulf of Mexico during seismic operations, with the closest whales observed at least 50 km away from an active seismic survey. However, the findings of several other studies differ substantially as follows:

- Madsen *et al*. (2002) reported that sperm whales exposed to sound pressures of 124 dB re 1 µPa did not change behaviours or avoid seismic surveys; rather, whales reportedly remained in the survey area for at least 13 days of exposure;
- Weir (2008) reported that encounter rates did not differ with operational status of an acoustic source, and although the mean distance to initial sighting was greater during full-scale acquisition, this effect was not statistically significant;
- Stone and Tasker (2006) reviewed data from of over 200 seismic surveys in UK waters and detected no statistically significant behavioural effects of seismic activity on sperm whales;
- Jochens *et al.* (2016) report on a sperm whale tagging study in the Gulf of Mexico from 2000 to 2003. Eight sperm whales were tagged and tracked before, during, and after playback of seismic noise. All whales maintained their course of travel and did not avoid the simulated seismic noise; however, two whales showed dive changes indicative of avoidance by deep-diving during full-array exposure, and all whales responded in a fashion expected to result in reduced energetic expenditure (i.e. lowered number of pitching movements); evidence of an effect on foraging behaviour. There was no obvious distance response to play-back pulses at a range of 20 km (Jochens *et al*., 2016); and
- Winsor *et al*. (2017) monitored sperm whale distribution by satellite tag (n = 51 tagged whales) in relation to seismic survey activity in the Gulf of Mexico. Statistical analysis to determine if whale distribution varied from that expected under spatially random conditions concluded that there was no evidence of horizontal avoidance.

Changes in dolphin behaviour were assessed during a seismic survey in the North Atlantic Ocean by Moulton and Miller (2005). Several species (common, Risso's, striped and spotted dolphins) were consistently observed when acoustic sources were active; however, some minor avoidance behaviours were noted whereby distance to initial sighting was smaller when the acoustic source was inactive. Bow-riding of the seismic vessel was also observed (at 350 m from the active source) as was feeding during acquisition periods. Moulton and Miller (2005) estimated that dolphins were subject to sound levels exceeding 180 dB re 1 µPa (rms) within 700 m of the active source. In contrast, Stone and Tasker (2006) reported that dolphins exhibit greater horizontal avoidance of seismic operations than baleen whales, killer whales, and pilot whales. However, it is generally accepted that dolphins are less likely to be disturbed by seismic operations (and are less vulnerable to acoustic trauma) than baleen and larger toothed whales, as the frequency of noise generated by seismic operations is substantially lower than the high frequency hearing sensitivities of most dolphin species. This view is clearly stated in Policy Statement 2.1.

Significant behavioural effects on harbour porpoises have been reported by Thompson *et al*. (2013), noting that the hearing sensitivity of porpoises occurs in a higher range (VHF) than that of most dolphins (HF) (Southall *et al.,* 2019). Thompson *et al.* (2013) reported that harbour porpoises were displaced from an active 470 in^3 acoustic source array over ranges of 5 – 10 km during a 2D seismic survey (received SPLs of 165 – 175 dB re 1 µPa and SELs of 145 – 151 dB re 1 µPa s^{-1}) but displaced animals returned to the acquisition area within a few hours of seismic operations ceasing (Thompson *et al*., 2013). Thompson *et al*. (2013) concluded that prolonged exposure to underwater noise from seismic surveys did not lead to significant broad-scale displacement of this species. It is noteworthy that the acoustic source reported by Thompson *et al*. (2013) was substantially smaller than that proposed for the Otway Basin 3D MC MSS.

For larger odontocetes, Stone and Tasker (2006) made the following observations:

- Killer whales showed some spatial avoidance around seismic operations, remaining further from an active acoustic source, than an inactive one, although no reduction in sighting rate in response to an active source was observed; and
- Pilot whales also showed little response to an active acoustic source; the only observed effect being a change in orientation with more movements away from, and fewer movements towards an active source.

Because beaked whales are difficult to observe at sea, the behavioural effects of seismic surveys on this group are largely unknown, but beaked whales are believed to be particularly sensitive to anthropogenic underwater noise. Research to date has focussed on responses to mid-frequency active sonar which has been implicated in multiple stranding events (Simonis *et al*., 2020). In addition, behavioural responses of beaked whales to underwater noise include increased swim speed, and unusual dive behaviours (Stimpert *et al*., 2014). Although the sound source generated by sonar is substantially different to that of seismic surveys, in the absence of specific data on the effects of seismic surveys on beaked whales, their responses to sonar are informative in a broad sense.

Based on the available information, temporary avoidance is clearly the most widely reported behavioural response to seismic surveys (Stone and Tasker, 2006). As the distribution of marine mammals is typically closely linked to that of their prey, avoidance behaviours could lead to abandonment of valuable feeding grounds (e.g. large aggregations of krill or fish) or reduced foraging effort. Seismic operations can also cause changes in abundance and distribution of prey (e.g. fish; Pearson *et al*., 1992; McCauley *et al*., 2000; Colman *et al*., 2008; Handegard *et al*., 2013, and zooplankton; McCauley *et al*., 2017) and lead to indirect effects (such as decreased foraging efficiency, higher energetic demands, lower group cohesion, higher predation rates and decreased reproduction rates) in marine mammals (Weilgart, 2007; Simmonds *et al*., 2004). Indirect effects are much more difficult to detect and measure than direct effects; however, they too are likely to vary with species, individuals, age, sex, past exposure, and behavioural state (IWC, 2007). **Section 7.2.2.2.1** provides more detail regarding the predicted effects of acoustic disturbance on the abundance and distribution of zooplankton, and implications for foraging baleen whales.

Overall, it is expected that marine mammals will elicit some behavioural responses during the Otway Basin 3D MC MSS, indeed (and as stated in Policy Statement 2.1) avoidance serves a protective role and is relied upon as a form of mitigation to prevent acoustic injury. The discussion above highlights that behavioural impacts are generally greater for baleen whales than odontocetes and on this basis, particular attention must be afforded to ensure adverse effects on threatened baleen whales are sufficiently managed by control measures. Species that are reliant on biologically important habitat in the vicinity of the OA (e.g. PBW and SRW) are of greatest potential concern. Noting that the BW Conservation Management Plan requires that marine activities must be managed in such a way that no blue whale will be displaced from a foraging area.

The underwater noise level at which behavioural disturbance is predicted for most marine mammal species is SPL 160 dB re 1 µPa (NOAA, 2019) (**Table 76**). However, behavioural effects resulting from seismic operations have been documented in some species at levels lower than this (see McCauley *et al*., 2000; Dunlop *et al*., 2017; 2017a; McDonald *et al*., 1995) indicating substantial variance in behavioural response between species, individuals, and sound levels. It is also noteworthy that severe behavioural responses are not consistently associated with higher source levels but are often influenced by context as well (i.e. by what behaviour an individual is engaged in) (Gomez *et al*., 2016; Pirotta *et al*., 2021). The NOAA (2019) 160 dB re 1 µPa SPL threshold is selected for this impact assessment as the level at which some biologically significant behavioural responses and avoidance may occur, such as avoidance by foraging, migrating and transient animals. This is broadly representative of the majority of observations reported in the literature cited above. In the risk assessment, the threshold has been applied to unweighted sound levels, as per NOAA (2019), but the acoustic modelling commissioned by TGS has also considered response levels weighted according to the LF cetacean functional hearing group, which is more biologically relevant to key species in the Otway region such as blue whales and southern right whales. More recently, Southall *et al.* (2021) provided recommendations and discussed nuances of assessing behavioural response but did not recommend new numerical thresholds for onset of behavioural responses for marine mammals due to the highly subjective and context-specific nature of the matter.

For the purpose of the Otway Basin 3D MC MSS, UAM was used to predict the maximum distance from the active acoustic source that this threshold is reached over several areas within or relevant to the OA (**Table 76**).

Table 76 Behavioural Response Threshold and Predicted Onset Distances for Marine Mammals

Marine mammal hearing group	Zones of impact – maximum horizontal distance from source to impact threshold levels		
	Criteria - SPL (dB re 1µPa)	Water Depth (m)	Range of maximum threshold distance (km)
All hearing groups	160	all	4.45 – 12.2

Animat modelling was undertaken to specifically assess the potential behavioural impacts on PBWs (males and females) and SRWs (both mothers with calves and unaccompanied adults) for the scenarios described in **Section 7.2.2.2.7**. Recognising that SRWs aggregate off the coast of Portland, Port Fairy and Warrnambool to calve, mate and rest, this EP has adopted a more precautionary impact threshold for these key life stages. The more precautionary weighted SPL criteria of 140 dB re 1 µPa, consistent with Wood *et al*. (2012) has been applied for the evaluation of potential impacts to SRW mother-calf pairs associated with the Aggregation BIA. This is considered representative of a potential avoidance response by LF cetacean mother-calf pairs given that other LF mother-calf pairs (i.e. humpback whale) were observed by McCauley *et al.* (2000, 2003) to display avoidance reactions at received SPLs of 140 dB re 1 µPa from seismic impulses while other cohorts reacted at higher levels (157– 164 dB re 1 µPa). The results of the Animat modelling are presented in **Table 77** and **Table 78**.

Table 77 Predicted Animat Behavioural Impact Onset Distances for Pygmy Blue Whales

Threshold		Scenario 1a				Scenario 1b			
		Female		Male		Female		Male	
	dB	ER95% (km)	P_{exp} (%)	ER95% (km)	P_{exp} (%)	ER95% (km)	P_{exp} (%)	ER95% (km)	P_{exp} (%)
Behavioural response (SPL)	160	6.05	83	6.21	80	7.01	41	6.82	51

Table 78 Predicted Animat Behavioural Impact Onset Distances for Southern Right Whales

Threshold		Scenario 2a				Scenario 2b			
		Mother & Calf		No calf		Mother & Calf		No calf	
	dB	ER95% (km)	P_{exp} (%)	ER95% (km)	P_{exp} (%)	ER95% (km)	P_{exp} (%)	ER95% (km)	P_{exp} (%)
Behavioural response (SPL unweighted)	160	-	-	-	-	6.10	73	6.06	76
Behavioural response (SPL weighted)	160	-	-	NA	NA	0.59	59	NA	NA
Behavioural response (SPL weighted)	140	31.5	61	NA	NA	30.0	81	NA	NA

Dashes indicate no simulated whales were exposed above threshold.

Summary of modelling results relevant to behavioural thresholds for marine mammals

The key results for behavioural effects as predicted from both the UAM and the animat modelling can be summarised as follows:

- For all marine mammal hearing groups (cetaceans and otariid seals), the UAM results predict that the behavioural response onset distance will occur between 4.45 and 12.2 km from the acoustic source (**Table 76**).
- For PBW, animat modelling predicts that in the offshore direction, the maximum range to the behavioural response onset threshold is approximately 6.2 km (Scenario 1a, **Table 77**) and in the inshore direction the maximum range is slightly greater, approximately 7 km (Scenario 1b, **Table 77**).
- Animat modelling results are particularly valuable in assessing the potential behavioural effects on SRWs, and the modelling specifically considers mother-calf pairs in the Aggregation BIA, as well as the connecting habitat, migration and resting on migration BIAs in coastal waters. Based on the animat results and the weighted 140 dB re 1 µPa SPL behavioural response threshold for mother calf pairs, behavioural effects could occur up to approximately 32 km from the seismic source on the continental shelf (**Table 78**). Further to this, Welch *et al.* (2023) report that the maximum weighted received SPL in the closest part of the Aggregation BIA (Area 1) is 141.5 dB re 1 µPa (see Table 35 of **Appendix B**). The maximum weighted received SPLs in the migration and resting on migration BIAs to the east and west of the Aggregation BIA are below 140 dB re 1 µPa SPL (see Table 35 of **Appendix B**).
- Regarding SRWs and for additional context, the unweighted equivalent of the 140 dB re 1 µPa SPL taken from the UAM results shows that levels may be exceeded approximately 42 km inshore of modelling sites closest to the Aggregation BIA (see Site 1 in Table 13 of **Appendix B**) and the unweighted received SPL in the closest part of the Aggregation BIA is approximately 144 dB re 1 µPa (see Area 1 in Table 35 of **Appendix B**).

- Using the combined UAM and animat modelling results as described for SRWs above, it is evident that if acquisition occurs on the upper continental shelf offshore from the Aggregation BIA, received levels within the outer limits of the BIA may exceed the weighted 140 dB re 1 µPa SPL behavioural response threshold for mother calf pairs, but that further inshore, this threshold will not be exceeded.

The model results can also be used to assess the potential impact of 2D tie line acquisition on marine mammals. This tie line extends onto the continental shelf and is oriented perpendicular to the bathymetric contours and shelf edge. This orientation results in the lower end-fire propagation ranges being directed towards coastal waters and, in particular, the SRW Aggregation BIA (Welch *et al.*, 2023). The tie line will involve only a few hours of acquisition on the continental shelf and the modelling demonstrates that unweighted SPLs received in the SRW BIAs will be approaching or below 140 dB re 1 µPa SPL. Weighted SPLs will be even lower. Therefore, no significant behavioural disturbance to mother-calf pairs is expected from acquisition of the 2D tie line.

General Controls to Address Potential Behavioural Effects

A comprehensive suite of survey design features, mitigations and management procedures are being proposed to minimise potential behavioural impacts to an **Acceptable Level**. A consolidated description of all controls is provided as **Appendix M**, and individual controls are discussed in **Table 85**.

On account of the Otway Basin 3D MC MSS having a 'high likelihood' of encountering whales, and the OA overlapping/approaching biologically important habitat, both standard management procedures (in accordance with Policy Statement 2.1) and additional management procedures are necessary to ensure that potential impacts on marine mammals are sufficiently addressed. The general Management Procedures (**MP 1 – 10**) will be implemented and will afford protection to all marine mammal species and ensure consistency with the purpose of the Australian Whale Sanctuary (that cetaceans are not killed, injured, or interfered). In addition, the following additional management procedures (**AMP**s) will apply to all operations:

- AMP 1: Soft start procedures throughout the OA can only proceed under the following circumstances:
  a. If no acquisition has occurred in the preceding 24 hours, soft starts may only commence in daylight hours and when conditions allow visual inspection of the 5+ km Observation Zone[AC];
  b. If acquisition has occurred within the preceding 24 hours and no whale initiated shut-downs have been made during this period, then soft starts may commence at night or during periods of low visibility providing they occur outside of the BW BIAs/buffer and the SRW Ag BIA/buffer.
- AMP 2: 2D tie line acquisition inside any BIA/buffer will only be permitted to occur in daylight hours, and two MFOs must be on duty on the Seismic Vessel and two MFOs must be on-duty on the Attending Support Vessel. 2D tie line acquisition inside any BIA/buffer can occur at any time providing the following criteria are met:
  a. An aerial survey has been conducted within 4 days of such operations commencing and no baleen whales have been detected. This aerial survey must focus on the area of planned acquisition that overlaps the BIA/buffer and must extend to at least 42 km on either side of the planned 2D sail line;
  b. 2D tie line acquisition inside any BIA/buffer must not occur for more than 12 hours total within any 24 hour period;
  c. The Extended Observation Zone as described in BMP 4 is implemented; and
  d. The acoustic source must not be active for more than a combined total of 20 hours (maximum) in the BIAs/buffers.

- AMP 3: Marine mammal observations made during the Otway Basin 3D MC MSS will be undertaken by dedicated, trained and experienced MFOs. All MFOs must have proven 'at sea' experience in whale identification and behaviour, and distance estimation, and must be confident in the identification of those species that the EP predicts will be present in the OA. All MFOs will hold a JNCC Marine Mammal Observation certification (or equivalent). In addition, the lead MFO on the Seismic Vessel must have logged a minimum of 20 weeks' relevant sea-time engaged in marine seismic survey operations in Australian waters as an MFO.
- AMP 4: A minimum of two MFOs will be onboard the Seismic Vessel for the duration of the Otway Basin 3D MC MSS and two additional MFOs will be stationed on the Attending Support Vessel.
- AMP 5: A passive acoustic monitoring (**PAM**) system will run 24 hours per day on the Seismic Vessel during the Otway Basin 3D MC MSS, with dedicated, trained and experienced PAM Operators conducting acoustic monitoring for the presence of cetaceans[27] while the acoustic source is active and during the 30 minutes before the commencement of any Soft Start Procedure.
- AMP 6: At least two dedicated, trained and experienced PAM Operators will be on the Seismic Vessel for the duration of the survey, with at least one PAM Operator maintaining 'acoustic watch' at all times while the acoustic source is active and during the 30 minutes before the commencement of any Soft Start Procedure.
- AMP 7: The lead PAM Operator must have logged a minimum of 20 weeks' relevant sea-time engaged in seismic survey operations in Australian waters as a PAM Operator. All PAM Operators will need to be able to demonstrate competency in the acoustic identification of the species that are likely to be present during the Otway Basin 3D MC MSS, and in interpreting acoustic software and estimating distance to any detected whale calls.
- AMP 8: A full replacement PAM system will be kept onboard the Seismic Vessel and will be used as a back-up if the PAM system malfunctions and is unable to be repaired.
- AMP 9: In the event that the PAM system malfunctions or becomes damaged, seismic operations may continue for 20 minutes without PAM while the PAM Operator diagnoses the issue. If it is found that the PAM system needs to be repaired or replaced, seismic operations may continue for an additional two hours without operational PAM as long as: a) it is daylight hours and the sea state is less than or equal to Beaufort 4, b) no whales were detected solely by PAM in the relevant mitigation zones in the previous two hours; c) two MFOs maintain watch at all times during seismic operations when PAM is not operational, d) seismic operations with an active source, but without an active PAM system, do not exceed a cumulative total of four hours in any 24-hour period.
- AMP 10: The PAM system will be programmed to receive/recognise vocalisations of whales within the frequencies 10 Hz to 200 Hz. The frequency range will theoretically be tuned to detect both low frequency vocalisations of baleen whales and the high frequency echolocations of sperm whales.
- AMP 11: PAMGuard software will be incorporated into the PAM system to assist with locating and classifying the vocalisations of marine mammals, and the PAM Operators will be suitably trained in using the PAMGuard software.

[27] PAM is not considered to be a particularly reliable method for detecting low-frequency cetaceans. On this basis, management measures for baleen whales have been developed to remove the reliance on PAM while still maintaining a high level of protection.

While species specific controls are outlined presently for blue whales and southern right whales, several adaptive management procedures (**ADMP**s) will be followed for 'other whales' throughout the entire OA for the duration of the Otway Basin 3D MC MSS, noting that the maximum onset distance predicted by UAM for behavioural effects was c. 12 km for all species.

- ADMP 1: If three or more 'other whale' instigated shut-downs occur within a 24-hour period, the Seismic Vessel will relocate at least 12 km in the direction away from the sightings before commencing Pre Start-up Visual Observations and Soft Start Procedures[28].
- ADMP 2: If an 'other whale' mother and calf pair is observed within 12 km[29] of the active acoustic source during the Otway Basin 3D MC MSS, the acoustic source will be immediately shut down and the Seismic Vessel will relocate to another area at least 12 km away from the last recorded position of the mother-calf pair before commencing Pre Start-up Visual Observations and Soft Start Procedures[30].

Specific Controls for Blue Whales

For PBWs, the maximum predicted onset distance for TTS is approximately 32 km (see **Table 71**) which exceeds the distance over which biologically significant behavioural avoidance and disruption to foraging behaviours are expected (6 – 7 km). On this basis the controls for BW/PBWs are largely underpinned by the predicted onset distances for TTS and are discussed at length in **Section 7.2.2.2.7**. The maximum predicted onset distance for behavioural effects for BW/PBW is 7 km. This distance directly informs the 7 km Extended Shut-down Zone for BW/PBW. Fundamental to managing the potential behavioural effects on foraging BW/PBWs is the proposed implementation of a spatio-temporal exclusion, whereby seismic operations will not be permitted within 16 km of any BW BIA during the months of January to June.

Specific Controls for Southern Right Whales

Animat modelling has been used to inform the development of the following control measures for SRWs. This modelling predicts the maximum onset distances for 24 hour cumulative PTS and TTS as 40 m and 11 km respectively. Based on these results, TTS effects are not predicted to extend from the OA into the Aggregation BIA (which occurs 14 km north of the OA) or any of the connecting habitat, migration and resting on migration BIAs that occur further afield in coastal waters. The predicted onset distance for behavioural effects for SRWs were assessed separately for 'mother-calf pairs' and 'other individuals' as 31.5 km and 6.1 km respectively. In keeping with the Shut-down Zone with BW/PBW, 7 km has been selected as the Shut-down Zone for SRW, to conservatively address the maximum predicted onset distance of 6.1 km for behavioural effects on individual (i.e. unaccompanied) SRWs. In addition to the Animat modelling and using a very conservative interpretation of the maximum-over-depth acoustic modelling results, behavioural effects to mother-calf pairs may indeed occur up to 42 km inshore of acquisition when it occurs closest to the Aggregation BIA.

[28] This measure is superseded by Additional Management Procedures applicable to BW/PBW and SRW.
[29] Note that the intention here is not to provide full MFO coverage of this zone, but to opportunistically respond to any mother-calf sightings that are detected within a 12 km radius. If the sighting occurs outside 12 km (i.e., during aerial surveys or support vessels en-route to resupply) no action will be required.
[30] This measure is superseded by Additional Management Procedures applicable to BW/PBW and SRW.

The operative SRW Conservation Management Plan (CoA, 2012) states that "*Noise interference is of particular concern within or close to southern right whale aggregation areas where young calves are present and whales are resident for long periods of time*"; hence the measures described below are targeted to address these specific noise impacts. While there is another designated 'known core range' BIA in the area, the OA only marginally overlaps with this, and the expectation is that animals traverse this area on their way to and from the more coastal aggregation areas and connecting habitat. Strong adaptive management measures have been developed to address potential noise effects in the wider area.

The 42 km onset distance for behavioural impacts to mother-calf pairs has been used to define a buffer zone around the SRW Aggregation BIA (referred to as the **SRW Ag BIA** herein). No acquisition will occur within the SRW Ag BIA or the 42 km buffer during the core aggregation months of May to September (SWIFFT, 2023). The only exception allowed is the acquisition of the 2D tie line which will be subject to additional operational restrictions (see **AMP 2** in **Appendix M**) and will only take approximately 12 hours to acquire.

This spatio-temporal measure has been designed to eliminate any physiological or behavioural effects on SRWs in the SRW Ag BIA during the months over which SRWs are expected to be present. On this basis, compliance with Interim Recovery Objective 5 of the operative Southern Right Whale Conservation Management Plan that anthropogenic threats are demonstrably minimised, is achieved. This control also aligns with the recommendation in Policy Statement 2.1 that seismic surveys should be undertaken outside of biologically important areas at biologically important times.

While the Draft National Recovery Plan for the Southern Right Whale (CoA, 2022) is not yet operative, once finalised it will supersede the current operative plan. The conservation actions included in the draft plan that are of relevance to seismic survey noise are listed in **Table 80** along with how they are addressed by the proposed controls. TGS is aware that the designated BIAs are also being reviewed as part of the process underpinning the review of the recovery plan. There is a strong possibility that the BIA boundaries for SRWs will change prior to the commencement of the proposed survey. TGS can confirm that the 42 km buffer as described above will be applied to the updated aggregation/reproductive BIA should it be published before the survey commences.

Table 79 Assessment of proposed controls against the draft conservation actions outlined in the Draft National Recovery Plan for Southern Right Whales (CoA, 2022)

Draft Actions of Relevance to Anthropogenic Underwater Noise (Action Area A5)	How Addressed by the Proposed Controls
Improve baseline understanding of SRW acoustic communication to better assess potential impacts from anthropogenic underwater noise.	The EP relies on the best available data as included in the Animat modelling undertaken by JASCO regarding SRW behaviour and acoustic communication.
Actions within and adjacent to SRW BIAs and 'Habitat Critical to Survival' should demonstrate that it does not prevent any SRW from utilising the area or cause injury (TTS and PTS) and/or disturbance.	The proposed 7 km Shut-down Zone prevents all PTS and single pulse TTS. Noting that cumulative TTS is predicted only if a SRW remained within 11 km of the active source for 24 hours. However, the vessel movement (average 8 km/hr) means that in practice TTS is unlikely as the vessel would be well beyond the TTS onset distances within 2 hours (i.e. much shorter than the 24 hrs of exposure needed to induce TTS). The 7 km Shut-down Zone protects all unaccompanied SRWs against behavioural effects (which are predicted to only occur to 6.1 km) and the 42 km buffer around the SRW Ag BIA protect mother calf pairs from behavioural disturbance. In addition, if a mother calf pair is detected outside the SRW Ag BIA/buffer (which could occur as they move south at the end of the breeding season), a shut-down will be triggered at any distance to prevent disturbance. In addition, no acquisition will occur within the SRW Ag BIA or the 42 km buffer during the core aggregation months of May to September.
Ensure environmental assessments associated with underwater noise generating activities include consideration of national policy (e.g. Policy Statement 2.1) and guidelines related to managing anthropogenic underwater noise and implement appropriate mitigation measures to reduce risks to SRWs to the lowest possible level.	The EP contains a comprehensive assessment of the potential effects of underwater noise on SRWs. The survey adopts Policy Statement 2.1 and oftentimes exceeds the requirements of this policy statement to ensure that the risks to SRWs are reduced to the lowest possible level.
Quantify risks of anthropogenic underwater noise to SRWs, including behavioural disturbance, changes to vocalisations, and physiological effects to whales.	The EP contains a comprehensive assessment of the potential effects of underwater noise on SRWs, and Animat modelling has been conducted to specifically quantify the risks of underwater noise.
Prioritise government/industry funding opportunities to support research to identify short and long-term responses of SRWs to underwater noise.	TGS is in dialogue with Blue Whale Study regarding the implementation of aerial surveys during the proposed seismic survey.
Improve understanding and characterisation of marine soundscapes, including the application of new technologies for data processing, within Southern Right Whale BIAs to facilitate quantification of anthropogenic noise in the marine soundscape.	Animat modelling has been conducted to specifically quantify the risks of underwater noise. In particular, two scenarios were modelled, one of which was specifically tailored to assess the effects of underwater noise in the SRW Ag BIA. The model was run for both mother-calf pairs and all other cohorts of unaccompanied SRWs.

The modelling took a conservative approach, whereby 1) the worst-case scenarios for noise propagation were modelled to produce maximum estimates of onset distances for TTS, PTS and behavioural effects, and 2) the modelled source locations and inputs were those expected to exhibit noise propagation over the greatest distances.

Operations inside the SRW Ag BIA and the 42 km buffer (referred collectively as **SRW Ag BIA/buffer** herein) will be permitted outside these months including during the aggregation shoulder months of April and October. All operations inside the SRW Ag BIA/buffer during the shoulder months will be subject to the use of aerial surveys to assist with SRW detection.

Throughout the survey an Extended Observation Zone (as described in **SRMP 4** below) will be implemented and will serve the dual purpose of detecting SRWs at extended distances in order to implement the 7 km Extended Shut-down Zone and to assist with survey planning in order to facilitate operational avoidance of areas where SRWs are present. Several adaptive management measures are also proposed.

In light of the conservative approach taken by the modelling, the proposed controls (as summarised above and detailed below) demonstrate consistency with the objective of the SRW Conservation Management Plan (that anthropogenic threats are demonstrably minimised) and the purpose of the Australian Whale Sanctuary (that cetaceans are not killed, injured, or interfered).

The adoption of the controls summarised above and detailed in the specific control measures below ensures that the protection afforded to SRWs, both inside the SRW Ag BIA and outside, is very strong and that the risks to SRWs are reduced to the lowest possible level.

The following additional and adaptive management procedures for SRW (denoted with **SRMP**) will be implemented during the Seismic Survey:

- <u>SRMP 1:</u> A 42 km buffer will be established around the SRW Ag BIA where it approaches the OA.
- <u>SRMP 2:</u> The Seismic Vessel will not activate the acoustic source(s) within the SRW Ag BIA/buffer from May to September (inclusive) which represents the core aggregation months during which SRWs are expected to be present here. The only exception allowed relates to the acquisition of the 2D tie line in accordance with the criteria outlined in **AMP 2** in **Appendix M**.
- <u>SRMP 3</u>: A 7 km Extended Shut-down Zone will be implemented for SRWs throughout the OA (including the SRW Ag BIA/buffer). On this basis a Low Power Zone is deemed unnecessary.
- <u>SRMP 4</u>: An 'Extended Observation Zone' will be adopted such that vessel based MFOs observe for SRWs as far as practicable, and to a minimum of 7 km during daylight hours. During periods when visibility is < 7 km, the Extended Observation Zone will be monitored by the combined efforts of the MFOs on both the Seismic Vessel and at least one Support Vessel travelling approximately 5 – 7 km ahead of the Seismic Vessel. This Support Vessel will focus monitoring efforts on the 90° quadrant that lies directly ahead of the Seismic Vessel, and in reference to these specific duties, is herein referred to as the EOZ Support Vessel. When visibility is > 7 km, this Extended Observation Zone may be monitored solely by MFOs on the seismic vessel. At these times the EOZ Support Vessel will be available to assist with vessel operations and port calls; however, whenever possible the intention is that the EOZ Support Vessel shall maintain its position 5 – 7 km ahead of the seismic vessel to assist with SRW detections. The only permissible exceptions to the specified EOZ Support Vessel duties will be issues of safety that require relocation of the EOZ Support Vessel or in the event of incidents involving significant risk to in-sea equipment when the EOZ Support Vessel will be permitted to temporarily assist providing the following criteria are met:
    a. The MFO onboard the EOZ Support Vessel continues observations for SRWs;
    b. There have been no SRW instigated shut-downs in the preceding 6 hours; and

c. No more than 4 hours elapse before the EOZ Support Vessel resumes its position ahead of the Seismic Vessel.

- SRMP 5: Low Visibility or Night-time Operations may occur provided that no SRW shut-downs have been instigated during the preceding 24 hours within 42 km of the planned acquisition (i.e. the survey lines that will occur during the hours of darkness or the period of low visibility).
- SRMP 6: During April and October (shoulder aggregation months) the Seismic Vessel is permitted to operate in the SRW Ag BIA/buffer in accordance with the following protocols:

a. All reasonable efforts will be made to ensure aerial surveys will be conducted to assist with the detection of SRWs in the SRW Ag BIA/buffer during April and October. Within the seven days prior to commencement of any acquisition in the SRW Ag BIA/buffer, aerial surveys will be flown, if possible, to identify any SRW that may be present. Any such detections will result in acquisition within the SRW Ag BIA/buffer being redirected away from areas in which such detections have been made. The intent of this control is to allow TGS to respond adaptively to detections of SRWs in the SRW Ag BIA/buffer by relocating to parts of the OA where potential impacts on SRWs are less likely.

b. If the requirement for aerial surveys as outlined in (a) above cannot be achieved, no low visibility or night-time operations may occur inside the BW BIAs/buffer until such time as the aerial survey requirement is met.

c. Aerial survey efforts will concentrate on the area of the SRW Ag BIA/buffer nearest to those waters that will be subject to acquisition in the first 24 hours of planned seismic operations. Aerial surveys should also monitor any nearby waters of the known core range BIA that acquisition will soon occur in. Throughout the period in which acquisition in the SRW Ag BIA/buffer is underway, aerial surveys will be flown periodically as weather permits to support the detection of SRWs and to redirect seismic survey efforts in order to avoid areas where SRWs are present.

d. Aerial surveys must be undertaken by two experienced observers from a suitable aircraft. At least one of these observers must demonstrate previous experience in the detection and identification of SRW from the air.

e. Start-up (via soft start) can only commence in the SRW Ag BIA/buffer during April and October if the following criteria are met:

i. A minimum of two hours of daylight remain before nightfall;

ii. Good sightings conditions prevail that allow visual observations of the Extended Observation Zone;

iii. A Support Vessel is available to undertake the requisite marine mammal monitoring;

iv. MFOs on board the Seismic Vessel and the EOZ Support Vessel have completed at least 30 minutes of pre-start observation procedures and confirmed no SRWs have been sighted; and

v. The start-up location does not occur within 42 km of an area where a SRW detection has been made in the last four days.

- SRMP 7: If a SRW is detected in the 7 km Extended Shut-down Zone during the Otway Basin 3D MC MSS the acoustic source will be immediately shut-down and the seismic vessel will relocate to another area at least 11 km away from the last SRW (unaccompanied) sighting before commencing Pre Start-up Visual Observations and Soft Start Procedures. Note that this distance increases if a calf is present in accordance with **SRMP 10**. If relocation of the seismic vessel is not possible, then acquisition will cease and will not recommence until 24 hours have elapsed and no SRW has been detected in the 7 km Extended Shut-down Zone.
- SRMP 8: A Start-up Delay will occur if a SRW enters or is detected in the 7 km Extended Shut-down Zone during soft start, and soft start procedures may only resume once the SRW is observed to move outside this Shut-down Zone or 30 minutes have lapsed since the last SRW sighting.
- SRMP 9: If higher than anticipated numbers of SRW are observed (three or more SRW instigated shut-downs are made during the preceding 48 hour period[31]) at any time or location during the Otway Basin 3D MC MSS, the following adaptive management controls will apply:
    a. Acquisition in the SRW Ag BIA/buffer must cease
    b. Low Visibility or Night-time Operations must cease;
    c. The acoustic source will be shut-down and the Seismic Vessel will relocate to another area at least 42 km away from the last SRW sighting, and outside of the SRW Ag BIA/buffer, before commencing Pre Start-up Visual Observations and Soft Start Procedures. If relocation of the seismic vessel is not possible, then acquisition will cease and will not recommence until 24 hours have elapsed and no SRW has been detected in the 7 km Extended Shut-down Zone; and
    d. Normal operations may only resume after 24 hours of no SRW instigated shut-downs.
- SRMP 10: If a SRW mother and calf pair is observed from the Seismic Vessel or the Attending Support Vessel at any distance during the Otway Basin 3D MC MSS, the acoustic source will be immediately shut-down and the Seismic Vessel will relocate to another area at least 42 km away, and outside of the SRW Ag BIA/buffer, before commencing Pre Start-up Visual Observations and Soft Start Procedures. If relocation of the seismic vessel is not possible, then acquisition will cease and will not recommence until 24 hours have elapsed and no SRW has been detected in the 7 km Extended Shut-down Zone.

7.2.2.3.6.1 Assessment Summary – Behavioural Effects on Blue Whales

Dedicated, trained, and experienced MFOs will be on watch at all times during daylight hours to monitor for marine mammals. The 7 km Extended Shut-down Zone for BW/PBWs provides excellent protection from behavioural disturbance, and the 16 km buffer zone around the BW BIAs and associated spatio-temporal controls well exceeds the predicted onset distance for behavioural impacts (which according to animat results could occur out to c. 7 km for this species). On this basis, full protection against significant behavioural disturbance for BW/PBWs is provided.

TGS will also implement both spatial and temporal exclusions to minimise the potential effects of underwater survey noise on foraging whales. No acquisition will occur within the BW BIAs or the 16 km buffer during the 'peak feeding season' from January to June (inclusive) based on the expected consistent and widespread presence of whales in the foraging areas during these months (Gill *et al.*, 2011; 2015; McCauley *et al.*, 2018). This spatio-temporal control represents best international practise for minimising noise disturbance in areas of high density and biological importance during key periods (following Chou *et al.*, 2021). The only exception permitted will be the acquisition of the 2D tie line which will be subject to additional operational restrictions and will only take approximately 12 hours to acquire.

[31] Note that any unidentified whale/s will contribute to this count.

These proposed control measures for BW/PBW have been designed to eliminate any behavioural effects on foraging BW/PBWs throughout the OA and to provide a very high level of protection to foraging whales in the BW BIAs during the peak foraging season; hence, to comply with the requirement of the BW Conservation Management Plan that no blue whale will be displaced from a foraging area.

It is therefore considered that the Otway Basin 3D MC MSS can operate in accordance with the requirements of the BW Conservation Management Plan by ensuring the continuation of biologically important behaviours and that residual environmental impacts and risks of the proposed Otway Basin 3D MC MSS on blue whales are managed to an **Acceptable Level**.

7.2.2.3.6.2 Assessment Summary – Behavioural Effects on Southern Right Whales

SRWs aggregate seasonally in coastal waters to rest, calve and breed, and the OA is largely situated beyond continental shelf waters, hence the potential for behavioural effects on SRWs is limited. Indeed, modelling results indicate that the shelf break is reasonably effective at restricting sound propagation towards sensitive coastal SRW habitat. However, if acquisition occurs on the upper continental shelf and in the vicinity of the Aggregation BIA, received levels on the offshore boundary of the BIA may exceed the weighted 140 dB re 1 µPa SPL behavioural response threshold for mother-calf pairs.

To manage the potential for behavioural disturbance to SRWs (in particular mother-calf pairs) in the SRW Ag BIA during the Otway Basin 3D MC MSS, acquisition will not be permitted within 42 km of this BIA during the core aggregation months of May to September, and aerial surveys will be required to increase the detection rates of SRWs within the 42 km buffer during the shoulder months of April and October. In addition, a 7 km Extended Shut-down Zone will be implemented throughout the OA. Based on the adoption of these control measures, no significant disturbance to SRWs in the SRW Ag BIAs is predicted to occur as a result of the Otway Basin 3D MC MSS. The proposed controls also address the requirements of the Draft National Plan for the SRW (CoA, 2022) and TGS notes that if the BIA boundaries change prior to the survey commencing, the 42 km buffer will be applied to the revised aggregation/reproductive BIA.

While knowledge of SRW distribution and migration pathways outside of the SRW Ag BIA and coastal migration corridors is limited, it is generally accepted that the migration pattern of this species is typified by counter-clockwise movement, whereby animals arrive in the east of Australia in May-July, peak in coastal aggregation areas (including those inshore of the OA) during July/August and then migrate west along the coast before departing in a southward direction in Sept/Oct towards higher latitude feeding grounds (Burnell, 2001). While this suggests that significant offshore movement in the vicinity of the OA will be limited, the possibility of SRWs occurring further offshore of the SRW Ag BIA and coastal migration BIAs cannot be dismissed, including the potential for mother-calf pairs to depart the coastal aggregation areas around Portland and transit south directly through the OA at the end of the breeding season. While several of the control measures for this species are linked to the SRW Ag BIA (temporal closure and aerial surveys) the 7 km Shut-down Zone will apply irrespective of location or season for this species (for unaccompanied SRWs), and further to this, any sighting of a SRW mother-calf pair will trigger a shut-down at any distance during the Otway Basin 3D MSS and a subsequent 42 km relocation (**SRMP 10**). This control measure provides strong protection to mother-calf pairs against behavioural disturbance.

7.2.2.3.6.3 Assessment Summary – Behavioural Effects on Other Whales

Predicted onset distances to the 160 dB re 1 µPa SPL behavioural response threshold ranged from approximately 4.5 km to 12 km depending upon the water depth. These onset distances are maximum-over-depth ranges that are strongly influenced by the greater propagation distances calculated for the deep portion of the water column. In reality onset distances are likely to be smaller, particularly for those species that do not routinely utilise deep waters for foraging.

While it is possible that some short-term disturbance and temporary behavioural effects could occur for baleen whales, in the most part the presence of species other than PBWs and SRWs is not expected to be consistent and is likely to be typified by low densities of transient individuals. For this reason, temporary behavioural disturbance is not expected to result in any impacts at the population level.

For HF and VHF cetaceans, the predicted onset distances for behavioural response are also likely to be conservative as energy from the seismic source is emitted primarily at frequencies lower than the hearing range of most dolphins and toothed whales. Overall, and based on the reduced hearing sensitivity of these species to low frequency seismic survey noise, the risk to HF and VHF cetaceans is limited.

Sperm whales and beaked whales, which are known to forage at depth, may be more susceptible to acoustic impacts as there is a greater likelihood that such species will be exposed, albeit for brief periods, to the maximum-over-depth SPLs calculated for the entire water column that are of lower relevance to species that do not make deep dives. While long-term displacement of sperm whales or beaked whales from foraging habitat is not predicted, low to moderate level behaviour responses cannot be dismissed if an individual in relatively close proximity to the acoustic source encounters a deep sound channel where SPLs may increase unexpectedly. The clicks and calls of sperm whales and beaked whales are however distinctive and detectable with PAM systems, which will be used during the Otway Basin 3D MC MSS and which will trigger a shut-down within 2 km.

Generally speaking, the survey design confers a degree of mitigation against behavioural disturbance to marine mammals as the OA is located in open ocean; hence, will not impact any confined water body; and the long survey lines will ensure that the Seismic Vessel will not focus in any specific area for a long period of time or expose any marine mammals to potential cumulative effects from acoustic noise being concentrated in one location.

While the 2 km Shut-down Zone for 'other whales' may not fully protect other baleen whale and large toothed whales species from behavioural disturbance under all circumstances, it does represent a significant extension on the standard Shut-down Zone of 500 m for whales as required by Policy Statement 2.1 and on account of the low densities of whales anticipated in the OA, no detectable adverse effects to any whale populations are predicted. As Conservation Management Plans are not available for all species with a potential presence in and around the OA, the following key considerations arise:

- Behavioural responses (especially displacement) are expected for most marine mammals and serve to protect marine mammals from hearing injury;
- Most other baleen whales are probably only present in and around the OA at low or very low densities; and
- On account of their different hearing sensitivities, odontocetes are less likely to be disturbed by seismic survey noise.

7.2.2.3.6.4 Assessment Summary – Behavioural Effects on Pinnipeds

Pinnipeds are sensitive to sound in both air and water (Southall *et al.,* 2007; Finneran, 2015; 2016; NMFS, 2018; Southall *et al.,* 2019). Pinniped species that may be encountered during the Otway Basin 3D MC MSS are all otariid seals (i.e. fur seals and sea lions) and include Australian sea lions, Australian fur seals, and New Zealand fur seals.

It is noteworthy that the OA does not overlap with any identified pinniped BIAs, and while non-threatened Australian and New Zealand fur seals are expected to be encountered (particularly New Zealand fur seals that are known to forage in offshore waters; Baylis *et al*. 2008), the likelihood of encountering threatened Australian sea lions during the Otway Basin 3D MC MSS has been assessed as low (see **Section 4.5.6.3.1**).

Of all the marine mammal hearing groups, that of otariid seals is thought to be the least sensitive to underwater noise (Southall *et al*., 2019). Behavioural responses in pinnipeds occurred in response to SPLs between 165 and 195 dB re 1 µPa (Southall *et al*., 2007) and included hauling out (possibly to avoid the noise) and temporary cessation of feeding (Bohne *et al*. 1985). Despite hearing sensitivities being low for otariid seals, NOAA (2019) suggests that the same threshold level (160 dB re 1 µPa SPL for impulsive sounds) is used to assess potential behavioural impacts to otariids. Using this threshold and based on the UAM results, behavioural responses of otariid seals may occur between approximately 7 km and 12 km from the seismic source on the upper continental slope (Area 1; <~1,600 m depth; Welch *et al*., 2023). Further offshore in deeper water depths (Area 2; >~1,600 m), the ranges for behavioural disturbance are less (approximately 4.5 to 6.6 km) (Welch *et al.,* 2023). Note that these ranges are calculated as maximums over depth, therefore, the ranges in the upper water column where animals are likely to be present (noting that dives mainly occur to depths of 10 – 100 m for all species, but New Zealand fur seals have been reported diving to depths > 200 m; see **Section 4.5.6.3.3**) will be significantly less.

Lalas and McConnell (2016) investigated the response of New Zealand fur seals to a large-scale offshore 3D seismic survey and found that the source vessel and towed gear created physical obstacles that generated responses from fur seals. The authors suggested that the acoustic source noise was not the only stimulus that generated a response from seals; with noise from the vessel engines or changes in wave pattern created by the vessel or towed gear also having an influence. When awake, seals also responded to the visual stimulus of vessel presence. Overall, Lalas and McConnell (2016) concluded that the vessel and towed gear create physical obstacles that generated more pronounced avoidance responses than those attributable to underwater noise.

Australian sea lions and Australian fur seals primarily forage on the continental shelf where the predicted onset distance to behavioural response is greatest. Hence, some behavioural disturbance to individuals foraging here cannot be dismissed. However, the constant movement of the Seismic Vessel coupled with individual avoidance responses suggest that long-term or ecologically significant effects are unlikely. The foraging range of New Zealand fur seals is broader and includes shelf waters and further offshore in the subtropical convergence zone. The foraging distribution of this species is, therefore, more likely to overlap with the OA than the other otariid species, even so, and following Lalas and McConnell (2016), disturbance effects from underwater noise are expected to be minor in magnitude.

Overall, it is expected that any behavioural disturbance to pinnipeds during the Otway Basin 3D MC MSS will be minor and short term in nature, whereby interruptions to foraging or at-sea resting behaviours of exposed individuals may occur. Such effects are not expected to have significant long-term implications for any individual or population. Sound levels that may result in behavioural disturbance will not extend to coastal waters around breeding colonies.

7.2.2.3.6.5 Conclusion – Behavioural Effects on Marine Mammals

In summary, with the implementation of the extensive control measures that have been specifically developed to consider all the different marine mammal sensitivities within the OA and surrounds, the residual risk of behavioural impacts to marine mammals from acoustic disturbance during the Otway Basin 3D MC MSS has been assessed as **Moderate** (*Minor x Certain*) as while some avoidance behaviours are expected, no detectable adverse effects to populations are predicted.

7.2.2.3.7 Seabirds

Although there is little information about the behavioural effects of MSSs on seabirds, several authors have raised the possibility of disruption to feeding activities, with foraging seabirds that may dive beneath the surface in particular of concern with regard to acoustic emissions from the acoustic source. Only birds diving and foraging within the AA have the potential to be exposed to significantly increased sound levels generated by the operating acoustic source while diving for prey near the sea surface.

Goudie and Ankney (1986) suggested that seabird feeding behaviours could possibly be interrupted by acoustic disturbance from the Seismic Vessel passing through feeding grounds; and MacDuff-Duncan and Davies (1995) postulated that birds in the area could be alarmed as the seismic operations pass close-by, causing them to temporarily stop diving. In addition to the potential direct displacement of seabirds, the displacement of bait fish could lead to a reduction in the diving activities and foraging potential for seabirds in the immediate vicinity of the seismic operations.

Birds resting on the surface of the water in proximity to the seismic vessel have limited potential to be affected by sound emissions underwater due to the limited transmission of sound energy between the water/air interface but may also be startled by seismic pulses in close proximity to the acoustic source. However, given the likely avoidance response from fish and other prey species in waters immediately surrounding the acoustic source (see **Section 7.2.2.3.2**), birds are unlikely to forage near the operating acoustic source. In the unlikely event that birds dive and forage near the acoustic source, this is likely to only affect individual birds, resulting in a startle response with the affected birds expected to move away from the area as a result. The consequence of this is expected to be negligible and impacts at a population level are extremely unlikely to occur.

It is noted that the behaviour and distribution of some fishes may be affected for short periods during and after exposure to the acoustic source (see **Section 7.2.2.3.2**). This may result in short-term and localised changes in the distribution of target prey species; however, these effects are unlikely to be discernible to foraging birds in the context of the normal movements and variation in the distribution of fishes.

Little penguins may be more susceptible to exposure to underwater sound due to their foraging behaviours whereby penguins swim and forage beneath the sea surface. Little penguins have not been identified as potentially present within the OA but are expected to be present within the wider EMBA (see **Section 4.5.7**). Lady Julia Percy Island, approximately 50 km north of the AA, is home to around 2,000 breeding pairs of little penguins. Little penguins were found to forage in discrete areas within a maximum distance of 5.6 km to 36 km from breeding colonies (Hoskins *et al.* 2008). McCutcheon *et al*. (2011) report that during the winter non-breeding period, some individuals conduct single-day trips 8 – 14 km from the colony, while other individuals conducted longer trips of 10 – 50 days and travelled over 200 km in some instances, although these movements where alongshore and remained in continental shelf waters.

Data on the underwater hearing sensitivity of penguins is limited and there are no regulatory thresholds or criteria established to assess potential hearing impairment or behavioural responses by diving birds to underwater noise. Pichegru *et al*. (2017) assessed the foraging behaviour of African penguins before, during and after an MSS that occurred within 100 km of breeding colonies. Penguins foraging within 100 km of the active acoustic source showed a change in foraging direction, increasing the distance between feeding areas and the Seismic Vessel. Displaced penguins reverted to normal foraging behaviours following the cessation of seismic activities, suggesting effects are relatively short-lived. It is worth noting that although the Pichegru *et al*. (2017) study was unable to differentiate between penguins shifting foraging activities in direct response to the survey (i.e. behavioural effect) or indirectly due to a change in prey distribution, a behavioural response was determined as the most likely cause. While the penguins were able to locate alternative feeding grounds, the displacement from traditional grounds resulted in an increase in energy expenditure (Pichegru *et al.,* 2017).

In a controlled exposure experiment, Sørensen *et al*. (2020) exposed captive gentoo penguins (*Pygoscelis papua*) to impulsive signals, and most animals showed strong aversive reactions at received levels above 120 dB re 1 µPa (SPL). While the experiment made efforts to reduce some of the limitations of captive experiments, the study is still difficult to reconcile exposures to sudden sound stimuli at close range (metres) in the absence of natural ocean background noise with a real-life exposure.

Lacroix *et al*. (2003) assessed the effect of seismic operations on the foraging behaviour of moulting male long-tailed ducks in the Beaufort Sea. Long-tailed ducks are incapable of flying during the moult and, to compensate for this nutritionally costly moult process, increase their foraging time during this period. The findings of Lacroix *et al*. (2003) indicated that the abundance and distribution of ducks in both seismic and control areas changed similarly following the start of seismic operations suggesting that other influencing factors (e.g. wind) were more important for duck distribution than seismic activities, and that seismic activity did not significantly change the diving intensity of ducks. Overall, Lacroix *et al*. (2003) concluded that there was no evidence to suggest any displacement away from active seismic operations.

Although the Lacroix *et al.* (2003), Pichegru *et al*. (2017) and Sørensen *et al*. (2020) studies were not carried out on species potentially present within the OA, and found differing results, their results suggest that at most seabirds will be temporarily displaced from areas of active seismic operations, and displacement effects will be short-lived, with animals able to return to traditional feeding grounds after the Seismic Vessel has moved away. Behavioural disturbance to little penguins on the outer continental shelf is also possible at times when acquisition is undertaken on the upper slope or within the 2D tie line AA. However, relatively few little penguins are expected to be encountered foraging offshore on the outer shelf.

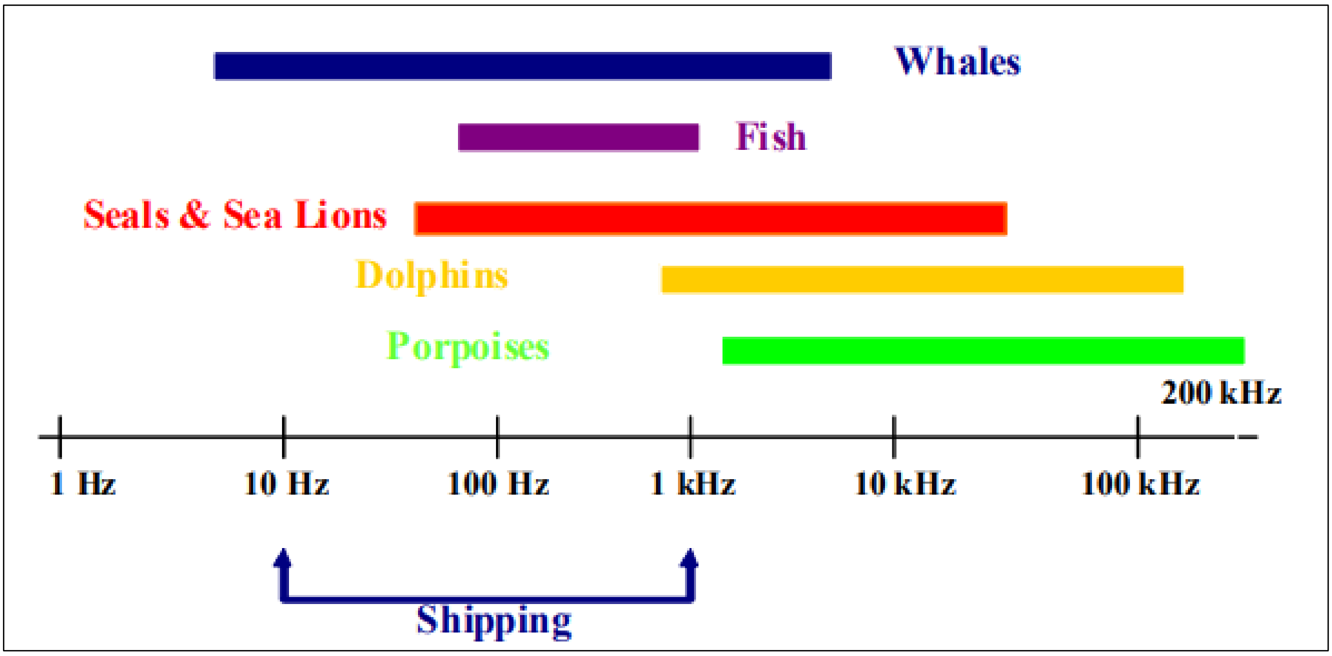
Consequently, the residual risk of behavioural impacts to seabird species from seismic sound exposure during the Otway Basin 3D MC MSS has been assessed as **Low** (*Minor* x *Unlikely*).

7.2.2.4 Potential Perceptual Impacts

Sound produced by marine animals serve server functions including navigation, communication, and predator and prey detection. Even those animals that do not produce sound utilise the surrounding soundscape to learn about, and gain and overall awareness of, the environment (Fay and Popper, 2000). Hearing in animals allows the extraction of information from surroundings in more detail and at larger distances than with any of the other senses (Popper and Hawkins, 2019; Rogers *et al*., 2021). The addition of anthropogenic noise into the marine environment can disrupt an animal's ability to communicate and/or detect biologically important signals (Dunlop *et al.,* 2010). 'Masking' is an increase in the threshold for detection of discrimination of one sound as a consequence of another (Brumm and Slabbekoorn, 2005) and occurs when sounds overlap in time, frequency, and direction with biologically relevant sounds (Dooling and Leek, 2018). Masking can be either complete, whereby the signal is not detected at all, or partial, whereby the signal is detected but unable to be properly understood (Clark *et al*., 2009). This can lead to effects on an animal's fitness and survival, through blocking/alteration of signals alerting to the presence of predators (Lowry *et al*., 2012), incorrect assessment of the quality of rivals or potential mates lowering reproductive success (Halfwerk *et al.,* 2011), and disruption in group cohesion through a breakdown in communication particularly between parents and offspring (Leonard and Horn, 2012).

The general low frequency band of shipping noise overlaps with the frequencies generated by marine fauna, particularly fish, whales, and pinnipeds (**Figure 82**) (Southall and Hatch, 2008). Masking of biologically significant sounds has been suggested to be the primary effect of vessel noise on marine fauna (Southall, 2005).

Section 7.2.2.4.1 and **Section 7.2.2.4.2** provide a discussion on the effects of masking on auditory communication of fish and marine mammals (particularly cetaceans).



Source: Southall and Hatch, 2008.

Figure 82 Typical Frequency Bands of Sound Produced by Marine Fauna compared to Sounds associated with Commercial Shipping

7.2.2.4.1 Fish

Several species of fish communicate with sound, with vocalisations typically within a frequency band of 100 Hz to 1 kHz (Ladich *et al*., 2006; Bass and Ladich, 2008). Fish typically listen for relatively low-frequency, broadband, crackling, clicking, or buzzing sounds with relevant variety in the temporal patterns and spectral composition (Amorim *et al.,* 2015). Although there have been no studies on the effects of MSSs on masking effects in fish (studies have focused on physiological and behavioural effects, see **Section 7.2.2.2.3** and **Section 7.2.2.3.2**, respectively), all fish species that have been the target of sound studies to date have been able to hear (Popper and Hawkins, 2019), and other anthropogenic sounds such as vessel noise have been reported to cause masking (e.g. Picciulin *et al*., 2012; Putland *et al*., 2017).

Popper *et al*. (2014) indicate that for fish species with good hearing there is a greater likelihood of masking further from the acoustic source than close to it as masking is more likely for these fish when the animals are far enough away from the source for the sounds to merge and become more or less continuous rather than distinct events. Radford *et al*. (2014) suggest five ways in which fish might temporarily adapt to overcome or reduce the effect of masking communications:

- Spatial or temporal avoidance: Temporal avoidance involves taking advantage of gaps or fluctuations in competing noise. For example, silver perch vocalise less frequently when recordings of a predator (bottlenose dolphin) were played (Luczkovich *et al*., 2000);
- Temporal adjustments: Signal detection enhances as signal duration increases as a consequence of an increase in the probability that some of the signal is detected during a quieter period. For example, male toadfish increase their call rate to compete acoustically in the presence of rival males (Fine and Thorsen, 2008);
- Frequency shifts: Broadband sounds are more difficult to detect in a noisy environment than pure tones. For example, freshwater gobies in waterfall habitats produce vocalisations in a frequency that differs from that of the waterfall noise; they utilise available ‘windows’ in the background frequency range (Lugli *et al*., 2003); and
- Change in signalling modality**:** The repertoire of a species usually consists of more than one signal component; hence when one signal type is ineffective, the caller may swap to another signal type to increase the chance of detection, e.g. a change from vocalisations to visual signals.

Rogers *et al.* (2021) reported on the potential for masking to occur in fish populations as a result of an experimental seismic survey in Bergen, Norway. The authors concluded that the acoustic emissions from the seismic survey were sufficiently above ambient noise up to 10 km from the acoustic source and as a result, the acoustic emissions may contribute to masking biologically relevant sound to fish up to that distance from the acoustic source (Rogers *et al*., 2021). These results support those of Pine *et al*. (2020), whereby the authors concluded that masking effects for Atlantic cod in between discharges of an acoustic source would continue as long as the masking noise and fish were within at least 11 km of each other. Maximum masking effects in terms of listening and communication range were within 1.6 km and 2 km respectively, resulting in complete masking on a stationary fish for at least 12 – 15 minutes based on the seismic vessel travelling at a speed of 5 knots (Pine *et al*., 2020). However, Pine *et al*. (2020) note that anti-masking strategies were not assessed in the study which may result in an overestimation of true masking effects.

Based on the above findings, the Otway Basin 3D MC MSS will likely have a masking effect on fish communication, however, masking will not have detectable adverse effects to populations and recovery from any impacts is expected to occur. As such, the residual risk of negative impacts to masking of fish communication based on exposure to seismic emissions associated with the MSS has been assessed as **Low** (*Minor x Possible*).

7.2.2.4.2 Marine Mammals

Marine mammals are reliant on sounds for foraging, navigation, communication, reproduction, parental care, avoidance of predators, and to gain overall awareness of the environment (Thomas *et al*., 1992; Johnson *et al*., 2009). Hence, the ability to perceive biologically important sounds is fundamental to the survival of these animals. Acoustic masking occurs when an anthropogenic noise reduces the ability of an animal to perceive a signal (Wood *et al*. 2012; Erbe *et al.* 2016a). Masking is a common effect of underwater anthropogenic noise on marine mammals (Erbe *et al*., 2016) and activities that generate anthropogenic noise are increasing both spatially and temporally in coastal and oceanic environments worldwide (Hatch *et al*., 2016). For masking to occur the anthropogenic noise must be loud enough, be of similar frequency, and happen at the same time (Wood *et al.* 2012). In addition, the level of any masking effect depends on the location of the sender and receiver, source level and spectral characteristics of the signal, and the receiver's auditory capabilities (Erbe *et al*., 2016).

Marine mammals are broadly separated into categories based on hearing capability (Southall *et al*., 2019). The following categories are of relevance to the species potentially present during the Seismic Survey:

- Low frequency cetaceans (auditory bandwidth between c. 0.007 kHz and 22 kHz). Include all mysticete whales, i.e. all baleen whales. Species from this group that could occur in the OA include BW, minke whale, fin whale, sei whale, SRW, humpback whale, Bryde's whale and pygmy right whale;
- High-frequency cetaceans (auditory bandwidth between c. 0.15 kHz and 160 kHz). Include most dolphins, beaked whales, sperm whales and killer whales. Species from this group that could occur in the OA include sperm whales, Shepherd's beaked whale, True's beaked whale, Arnoux's beaked whale, Andrew's beaked whale, southern bottlenose whale, Gray's beaked whale, Blainville's beaked whale, Hector's beaked whale, strap-toothed beaked whale, Cuvier's beaked whale, gingko-toothed beaked whale, killer whale, false killer whale, pilot whales, Risso's dolphin, bottlenose dolphins, southern right whale dolphin, dusky dolphin, and common dolphin; and
- Very-high frequency cetaceans (auditory bandwidth between 0.2 kHz and 180 kHz). Include true porpoises, most river dolphins, pygmy/dwarf sperm whales, and Commerson's, Chilean, Heaviside's, Hector's hourglass and Peale's dolphins. Pygmy sperm whales, dwarf sperm whales and spectacled porpoise are the only species from this group that could occur in the OA.

Aguilar Soto *et al*. (2006) reported that elevated received noise levels from a passing large ship (with a closest point of approach of 700 m) coincided with an unusual foraging dive in Cuvier's beaked whales, suggesting that elevated noise from shipping may interrupt foraging behaviours by masking echolocation and communication. Evidence suggests that blue whales (McDonald, 2006), killer whales (Holt *et al,* 2008), and North Atlantic right whales (Parks *et al*., 2007) can adjust the frequency and loudness of their calls to compensative for masking by vessel noise, while fin whales alter bandwidth and duration of calls in response to increasing background noise from shipping (Castellote *et al.,* 2012). Communication in two delphinid species (bottlenose dolphin and pilot whales) was also demonstrated to be reduced in the presence of vessel traffic, with communication range reduced by 26% within 50 m of a vessel travelling at 5 knots (Jensen *et al.,* 2009). Interestingly, while humpback whales increase the source levels of their songs in response to wind noise (Dunlop *et al*., 2014), it has recently been reported that in the presence of both wind and vessel noise (both of which overlap in frequency with humpback songs) the amplitude of their singing only adjusted to compensate for wind and did not increase additively to compensate for vessel noise as well (Girola *et al*., 2023).

The sound generated by seismic surveys comprises brief, low frequency pulses (in the order of tens of milliseconds), occurring several seconds apart. At great distances from the seismic source, sound levels will be quieter, but transmission of the sound via multiple pathways (water, seabed) and reverberation mean that the pulse duration increases with distance. However, given the short seismic pulse duration relative to the duration of marine mammal vocalisations (several seconds to several minutes or longer), marine mammals are likely to be able to detect calls in between seismic pulses (Wood *et al.*, 2012).

The sound frequencies that are emitted by seismic acoustic sources are broadband, but with most of the energy concentrated between 0.1 kHz and 0.25 kHz. The greatest potential for interference with cetacean vocalisations is at the highest end of the seismic spectrum and the lowest end of the cetacean vocalisation spectrum (**Table** 80); i.e. the lowest frequency cetaceans are particularly affected since they have the most overlap with the frequencies of the seismic survey acoustic sources (**Figure 83**). Auditory masking of HF and VHF cetacean vocalisations is less likely as these species generally operate at higher frequencies than those generated by a seismic survey.

Table 80 Cetacean Communication and Echolocation Frequencies

Species	Communication Frequency (kHz)	Echolocation Frequency (kHz)
Southern right whale	0.03 – 2.2	N/A
Minke whale	0.06 – 6	N/A
Sei whale	1.5 – 3.5	N/A
Blue whale	0.0124 – 0.4	N/A
Fin whale	0.01 – 28	N/A
Humpback whale	0.025 – 10	N/A
Sperm whale	<9	0.1 – 30
Pygmy sperm whale	No data available	60 – 200
Beaked whales*	3 – 16	2 – 26
Common dolphin	0.5 – 18	0.2 – 150
Pilot whale	1 – 18	1 – 18
Killer whale	0.1 – 35	12 – 25
Bottlenose dolphin	0.2 – 24	0.5 – 130
* = using the bottlenose whale as an example

Figure 83 Ambient and Localised Noise Sources in the Ocean

Several studies have documented compensation responses (anti-masking strategies) to anthropogenic underwater noise, including changes in vocalisation strength, frequency, and timing. (Erbe *et al*., 2016). For example, blue whales increased their calls (emitted during social encounters and feeding) when a seismic survey was operational in the area (Di lorio and Clark, 2010). Such adaptations have also been reported for humpback whales (McCauley *et al*., 1998; 2003b), beluga whales (Lesage *et al*., 1999), right whales (Parks *et al*., 2007, 2011), killer whales (Holt *et al.*, 2008), and bottlenose dolphins (van Ginkel *et al*., 2017). It is thought that increased calling enhances the probability that communication signals will be successfully received by conspecifics by reducing the effects of auditory masking.

Marine mammals may also cease vocalising in response to anthropogenic noise, as has been demonstrated in humpback whales at breeding grounds off Angola during a seismic survey. In this study, singing activity declined as received levels of seismic noise increased (Cerchio *et al*., 2014). This response is not novel to seismic surveys, with humpbacks also halting vocalisations in response to emissions from acoustic fisheries tools (Risch *et al.,* 2012). Cessation in clicking was also observed in sperm whales by Bowles *et al.* (1994) in response to weak seismic survey noise (received level of 115 dB re 1 µPa); however, contradictory to the findings of Bowles *et al.* (1994), Madsen *et al*. (2002) did not document any changes in male sperm whale clicks in response to an MSS off Norway. Sperm whales did not cease clicking and did not seem to alter their normal acoustic behaviour during feeding (Madsen *et al*., 2002). Decreases of three echolocation parameters (number of clicks per minute, minutes with detectable click trains and feeding buzz frequency) were also reported for harbour porpoises in the Danish North Sea within an 8 – 12 km radius of seismic acquisition (Sarnocinska *et al*., 2020). The authors of this study provided evidence to suggest that displacement of porpoises was not the main driver of this effect, but instead that the results instead suggest a change in echolocation behaviour representing a decrease in porpoise foraging efficacy.

Bowhead whales in the vicinity of an active seismic source varied their calling rate as received SELs changed (Blackwell *et al*., 2015). At very low SELs (only just detectable) calling rates increased. As SELs continued to increase, calling rates levelled off (as SELs reached 94 dB re 1 µPa^2-s), then began decreasing (at SELs greater than 127 dB re 1 µPa^2-s), with whales falling virtually silent once SELs exceeded 160 dB re 1 µPa^2-s. Hence adaptations to masking for some species may be limited to circumstances when whales are subject to only low to moderate SELs. Similar results were also reported by Thode *et al*. (2020) where bowhead whale call density increased with exposure to weak SELs from MSS (a 10 – 15 dB increased above ambient noise) and then dropped with increasing cumulative SELs. This study confirmed that whales could completely compensate for MSS noise at low received levels (with whale call volume increasing by nearly 20 dB), but this ability increasingly diminished as MSS noise levels rose; to the point where a 40 dB increase in cumulative SEL (from MSS) prompted call level increases of only a few dB whereby whale communication space was substantially compromised.

Blue whales vocalise at a low frequency (average of 0.01 – 0.110 kHz) (McDonald *et al*., 2001; Miller *et al*., 2014), meaning that their calls can travel hundreds of kilometres underwater. The amplitude of their calls can reach levels of up to 188 dB re 1ɥPa m-1 (Aroyan *et al*., 2000; Cummings and Thompson, 1971). PAM has proven to be ineffective at detecting the low frequencies of blue whale calls and some other baleen whales. While TGS will utilise a PAM system during the Otway Basin 3D MC MSS (**Appendix LJ**) this system will primarily be useful for detecting HF and VHF cetaceans, (particularly sperm whales). Mitigations for baleen whales have been designed without reliance on PAM detections as PAM is not particularly effective at detecting LF cetaceans.

It is likely that marine mammals in the vicinity of the OA during the Otway Basin 3D MC MSS may be subject to some masking effects. In particular, the frequency of baleen whale calls overlaps directly with the low frequency seismic operations (**Figure 83**). The long survey lines of the Otway Basin 3D MC MSS will reduce the potential for significant masking effects as underwater noise from the active source will be transitory throughout the OA (i.e. not focused in any one area for an extended period). A comprehensive suite of control measures will be implemented during the Otway Basin 3D MC MSS to minimise potential impacts to cetaceans that may arise from the effects of acoustic disturbance (**Table 84**).

Masking levels are difficult to predict, and no auditory thresholds exist for predicting masking effects on marine mammals (Erbe *et al*., 2016); however, as outlined above masking responses (e.g. changes in calling rates) have been documented to occur at relatively low exposure levels (i.e. lower than would elicit any behavioural response). The UAM results for the Otway Basin 3D MC MSS clearly predict relatively high cumulative SELs (**Table 70**); hence sound levels sufficient to elicit masking will certainly occur in the OA and surrounding waters. Any masking effects will however cease at the completion of the survey and are highly unlikely to have detectable population level effects on any marine mammal species. On this basis the residual risk of impacts to noise perception by marine mammal species from seismic sound exposure and vessel noise during the Otway Basin 3D MC MSS has been assessed as **Moderate** (*Minor* x *Certain*).

7.2.2.5 Potential Impacts and Risks on Protected and Sensitive Areas in the Marine Coastal Environment

Several protected and sensitive environments, species and habitats have been identified in the waters within the OA (**Section 4.4**). These include AMPs, KEFs, BIAs, and the Australian Whale Sanctuary.

The following sections provides an assessment on potential effects on the values within these protected and sensitive environments from noise emissions associated with the proposed Otway Basin 3D MC MSS. It is worth noting that the following sections have only focused on those sensitive areas that may be impacted by the acoustic disturbance associated with the Otway Basin 3D MC MSS OA.

7.2.2.5.1 Australian Marine Parks

The OA directly overlaps with two AMPs; the Nelson AMP and the Zeehan AMP. A further two AMPs are located within the wider EMBA, in relatively close proximity to the OA. These are the Apollo AMP and Franklin AMP, which lie 46 km and 42 km from the OA, however, this distance is considered sufficient to protect the Apollo AMP and Franklin AMP from the effects of acoustic emissions.

The conservation and management of these AMPs falls under the South-east Commonwealth Marine Reserves Network Management Plan 2013 – 2023 which sets out the management zoning and IUCN categorisation within each AMP and determines the activities allowed within each zone in accordance with the EPBC Act.

The categorisation and zoning consider the purposes for which the reserves were declared, the objectives of the Management Plan, and the requirements of the EPBC Act and associated regulations. The IUCN Category Zones for each of the AMPs is outlined within **Table 14** and a discussion on the key management principles and purpose of each AMP is also outlined within **Table 14**.

NOPSEMA Guidance Note "*Petroleum activities and Australian Marine* Parks' (N-04750-GN1785 A620236) states that "*Petroleum activities may be allowable in Multiple Use Zones and Special Purpose Zones (IUCN category IV) subject to environmental approvals and demonstration that environmental impacts will be consistent with the relevant management plan"* and that "*Titleholders undertaking petroleum activities in Australian waters must ensure that any potential environmental impacts from the petroleum activities are managed to be consistent with the relevant management plan".* The Zeehan AMP and Nelson AMP cover IUCN Category VI (Special Purpose Zone and Multiple Use Zone), as seen in **Figure 13**. The South-east Commonwealth Marine Reserves Network Management Plan 2013 – 2023 allows for MSSs within these areas in accordance with a class approval issued by the Director of National Parks. Class approvals are issued subject to conditions that are considered necessary, including to ensure the activity is conducted in a manner to avoid or minimise impacts. When an EP is being prepared for an offshore activity and there is potential to affect a marine park, the DNP must be consulted as a relevant authority under Regulation 11A of the Environment Regulations so that any objections or claims about environmental impacts of the activity on the marine park values can be made prior to the submission of the EP. The following criteria trigger the need for consultation with the DNP:

- Any proposed activity to occur **within** an AMP;
- Any proposed activity to occur **adjacent to** and AMP; and
- Any proposed activity that could affect an AMP's established values irrespective of where the activity takes place in relation to the park.

TGS has consulted with the DNP (see **Section 5** and **Appendix K**) throughout the development of this EP, with consultation continuing for the life of the EP. The DNP noted that the OA of the Otway Basin 3D MC MSS overlaps with the Nelson and Zeehan AMPs and if survey activities are not managed correctly, they could affect the parks' natural, social, and economic values. The DNP made the following objections and claims regarding noise emissions on sensitivities within the AMPs:

- Activities that may prevent of displace PBW or SRW use of BIAs are avoided;
- Activities are timed to avoid species' peak migration and foraging behaviours;
- Potential cumulative impacts upon species are addressed, including, but not limited to cetaceans (PTs and TTS) as well as impacts to availability of food (krill). Impacts to giant crab and southern rock lobster should be explored noting that some populations could be exposed to repeated surveys;

- Identify a comprehensive suite of whale detection measures including regular aerial surveillance flights to identify presence/absence/species and direction of movement and Pam to support the efficacy and reliability of shut-down protocols for marine mammals;
- Seismic array to operate at low power during line turns to minimise the risk of SRW and blue whale/PBW entering the zone of potential TTS or behavioural disturbance during shut-downs;
- Spatial avoidance of fishing grounds and, or, temporal avoidance of fishing seasons;
- Excising giant crab and southern rock lobster habitat within the canyon area in the southwest of the survey from the AA, consistent with that applied to the ConocoPhillips Sequoia survey;
- Reducing the overall area to be surveyed or splitting the area into smaller areas to be acquired to avoid peak utilization rates and reduce cumulative impacts upon the environment; and
- Set a limit to the number of days far acquisition at full power and, or the total distance of sail lines for acquisition at full power.

Furthermore, the DNP advised that in the context of the South-east Commonwealth Marine Reserves Network Management Plan 2013 – 2023 objectives and values, TGS should ensure that the EP:

- Identifies and manages all impacts and risks on AMP values (including ecosystem values) to an acceptable level and has considered all options to avoid or reduce them to as low as reasonably practicable; and
- Clearly demonstrates that the activity will not be inconsistent with the management plan.

The DNP noted that the AA is adjacent to, and overlaps with, the following biologically important areas:

- Foraging areas for numerous protected seabirds;
- Core use and range area for the SRW;
- PBW seasonal feeding aggregations are supported by upwelling systems located at the Bonney Upwelling system and adjacent waters off South Australian and VIC; and
- Presence of southern rock lobster and giant crab within the proposed AA, including previously excised areas in the recent ConocoPhillips acquisition.

To avoid unnecessary duplication in this EP, the values associated with the Nelson AMP and Zeehan AMP, and those identified by the DNP, and where the potential impacts on those values are addressed within this EP are outlined in **Table 81.**

An EP cannot be approved if the activity is likely to result in unacceptable impacts that are inconsistent with the IUCN principles and relevant Management Plan objectives. Based on the discussions within **7.2.2** along with the implementation of the control measures, it is considered that the Otway Basin 3D MC MSS will not be inconsistent with the IUCN principles and the South-east Commonwealth Marine Reserves Network Management Plan 2013 – 2023 objectives when operating within the OA.

Based on the risk assessments for all marine receptors, the total residual risk to AMPs within the OA from noise emissions arising from the Otway Basin 3D MC MSS has been assessed as **Low** (*Minor x Unlikely*).

Table 81 Conservation Values within the Nelson AMP and Zeehan AMP that may be affected by Acoustic Disturbance

Conservation Values	Location in EP for full assessment of acoustic effects on conservation values
Ecosystems, habitats, and communities associated with the Tasmania Province, West Tasmania Transition, Western Bass Strait Shelf Transition, and associated sea-floor features (abyssal plain/deep ocean floor, canyon, deep/hole/valley, knoll/abyssal hill, shelf, slope).	The Zeehan AMP covers some of the West Tasmanian Canyons KEF. This KEF is considered important as it supports a high biodiversity of benthic invertebrates and facilitates high productivity. Physiological and behavioural impacts of acoustic disturbances on benthic invertebrates are addressed in **Section 7.2.2.2.2** and **Section 7.2.2.3.1** respectively, with the potential risk of these impacts on benthic invertebrates assessed as at worst, low. Acoustic disturbance impacts on plankton/productivity have been assessed within **Section 7.2.2.2.1**, and have been determined to have at worst a low risk. Any impacts on sessile benthic invertebrates are expected to be temporary, localised and restricted to the parent population. Changes at the community level will unlikely be discernible from the natural variation observed. As with sessile benthic invertebrates, any potential impacts on productivity are also expected to be temporary and localised, with populations rapidly refreshed from the surrounding environment. Due to the temporary and localised nature of the effects, biodiversity will be protected and maintained in the long-term and the functioning and integrity of these benthic communities will be maintained. The Otway Basin 3D MC MSS will not be inconsistent with the principles and the objectives of the South-east Commonwealth Marine Reserves Network Management Plan 2013 – 2023.
Cetaceans: • Blue, humpback, fin and sei whale migrations; and • Seasonal feeding aggregations of PBW.	Potential impacts on whales (including migrations) have been assessed in **Section 7.2.2.2.7** (physiological impacts), **Section 7.2.2.3.6** (behavioural impacts), and **Section 7.2.2.4.2** (perceptual impacts), which in turn directly relate to potential impacts on the PBW and SRW BIAs. The results of these sections found that, based on the control measures that will be implemented for the Otway Basin 3D MC MSS, the impacts are at worst moderate. Due to this and the control measures in place to manage any potential impacts on whale migrations, it is considered that the Otway Basin 3D MC MSS will not be inconsistent with the principles and objectives of the South-east Commonwealth Marine Reserves Network Management Plan 2013 – 2023 regarding migrating and foraging cetaceans.

Conservation Values	Location in EP for full assessment of acoustic effects on conservation values
Seabird foraging – black-browed, wandering, and shy albatrosses, and great-winged and cape petrels.	Potential impacts on seabirds have been assessed in **Section 7.2.2.2.8** (physiological impacts) and **Section 7.2.2.3.7** (behavioural impacts). The results of these sections found that the impacts of acoustic disturbance directly on seabirds are at worst low. However, impacts of acoustic disturbance on seabird prey at foraging areas must also be taken into consideration. Potential physiological impacts on zooplankton and fish, and behavioural impacts on fish have been assessed in **Section 7.2.2.2.1, Section 7.2.2.2.3**, and **Section 7.2.2.3.2** respectively. The results of these sections found that the impacts to seabird prey (zooplankton and fish) will be at worst low. Due to this, it is considered that the Otway Basin 3D MC MSS will not be inconsistent with the principles and objectives of the South-east Commonwealth Marine Reserves Network Management Plan 2013 – 2023 regarding foraging seabirds.
Southern rock lobster and giant crab.	Potential impacts on southern rock lobster and giant crab have been assessed in **Section 7.2.2.2.1** (physiological) and **Section 7.2.2.3.1** (behavioural). The results of these sections found that the impacts of acoustic disturbance on southern rock lobster and giant crab are at worst low. Furthermore, as discussed in **Section 7.1.3.1**, TGS will implement **a** Giant Crab Acoustic Exclusion Area (**Figure 74**) over waters that are 1,000 m or less along the eastern boundary of the AA. There will be no activation of the acoustic source within this exclusion area, providing protection to rock lobster and giant crab habitat from the highest acoustic emissions. Due to this, it is considered that the Otway Basin 3D MC MSS will not be inconsistent with the principles and objectives of the South-east Commonwealth Marine Reserves Network Management Plan 2013 – 2023 regarding foraging seabirds.

7.2.2.5.2 Biologically Important Areas

As discussed in **Section 4.4.4**, BIAs are spatially defined areas where aggregations of individuals of a species are known to display biologically important behaviours. While these areas have no legal status, several Conservation Management Plans outline recommendations for MSSs operating within a defined BIA. BIAs for marine mammals, seabirds and elasmobranchs have been registered within the OA; these include PBW (distribution and foraging), SRW (known core range), wedge-tailed shearwater (foraging), short-tailed shearwater (foraging), wandering albatross (foraging), Antipodean albatross (foraging), Australasian gannet (foraging), white-faced storm-petrel (foraging), common diving petrel (foraging), Buller's albatross (foraging), shy albatross (foraging), Indian yellow-nosed albatross (foraging), black-browed albatross (foraging), Campbell albatross (foraging), and white shark (distribution)(see summary in **Table 16**).

There are twelve species of threatened and/or migratory seabird species (classified by the EPBC Act) with BIAs that overlap with the OA. The potential impacts of acoustic disturbances on seabirds have been discussed in **Section 7.2.2.2.8** (physiological impacts) and **Section 7.2.2.3.7** (behavioural impacts). The residual risks from acoustic emissions during the Otway Basin 3D MC MSS on seabirds for potential physiological and behavioural effects have been assessed as Low. In addition to direct effects on seabirds, indirect effects on seabirds due to effects on prey (fish and plankton) have been assessed within this EP in **Section 7.2.2.2.1** (physiological effects on plankton), **Section 7.2.2.3.2** (physiological effects on fish), and **Section 7.2.2.3.2** (behavioural effects on fish).

As depicted in **Figure 21**, the OA overlaps with several BIAs for the white shark; distribution (two BIAs), low density distribution, and known distribution. However, as described within **Table 23**, these BIAs largely cover water depths outside of the OA, reducing the overlap of the OA with biologically important habitats for white sharks. The potential impacts of acoustic disturbances on white sharks have been discussed in **Section 7.2.2.2.4** (physiological impacts), **Section 7.2.2.3.3** (behavioural impacts), and **Section 7.2.2.4.1** (perceptual impacts). As a result, the residual risk of impacts to elasmobranchs (including white sharks) from seismic sound exposure during the Otway Basin 3D MC MSS has been assessed as **Low** for potential physiological impacts and as **Low** for potential behavioural impacts.

The known core range BIA for SRWs overlaps with the OA along the northern and eastern boundary. The total area overlap of the SRW known core range BIA with the Oa is 1,356 km^2. There is a moderate likelihood of encountering SRWs in and around the BIA, and therefore the inshore portion of the OA during the breeding season (September to October) and shoulder season (i.e April and October). The potential impacts of acoustic disturbances on SRW have been discussed in detail in **Section 7.2.2.2.7** (physiological impacts), **Section 7.2.2.3.6** (behavioural impacts), and **Section 7.2.2.4.2** (perceptual impacts).

PBW distribution, foraging, foraging (annual high use area) and known foraging area BIAs overlap with the OA along the northern and eastern boundary. The total area overlap of the PBW BIAs with the OA is 7.779 km^2. There is a high likelihood of encountering PBW in and around the BIAs during the core foraging season (January to June inclusive) and the foraging shoulder season (November/December and July). The potential impacts of acoustic disturbances on blue whales/PBW have been discussed in detail in **Section 7.2.2.2.7** (physiological impacts), **Section 7.2.2.3.6** (behavioural impacts), and **Section 7.2.2.4.2** (perceptual impacts).

All marine mammals in Australian waters are fully protected under the EPBC Act, therefore the potential for causing adverse effects during any MSS is taken extremely seriously. Animat modelling results from the UAM undertaken for the Otway Basin 3D MC MSS indicate that the standard Shut-down Zones recommended in Policy Statement 2.1 are insufficient to manage the risk of auditory impairment to baleen whales during the Otway Basin 3D MC MSS. Based on the results of the UAM, additional management procedures and control measures have been proposed and will be implemented for SRWs and PBWs during the Otway Basin 3D MC MSS when the acoustic source is active in the BIAs and buffer areas (see proposed control measures in **Section 7.2.2.2.7**, **Section 7.2.2.3.6**, and **Section 7.2.2.4.2** and a summary of all control measures for managing acoustic disturbance during the Otway Basin 3D MC MSS in **Table 84**).

With specific regards to the objectives of the SRW Conservation Management Plan, the Otway Basin 3D MC MSS will be consistent with the objectives of this plan, and it is considered that anthropogenic noise in the SRW known core range BIA will be managed through the survey design and implementation of the additional control measures so that SRWs may continue to utilise the area without injuries or behavioural disturbances. It is therefore considered that the residual environmental impacts and risks of the proposed Otway Basin 3D MC MSS on SRWs are managed to an **Acceptable Level**.

With specific regards to the objectives of the blue whale/PBW recovery plan, the Otway Basin 3D MC MSS will be consistent with the objectives within this recovery plan, and it is considered that anthropogenic noise in the PBW migratory BIA will be managed through the survey design and implementation of the additional control measures so that any blue whale/PBW may continue to utilize the area without injuries or behavioural disturbances. Therefore, it is considered that the residual environmental impacts and risks of the proposed Otway Basin 3D MC MSS on blue whales/PBWs are managed to an **Acceptable Level**.

The residual risk of potential physiological impacts on blue whales/PBWs and SRWs arising from acoustic disturbance during the Otway Basin 3D MC MSS has been assessed as **Low** (*Moderate* x *Rare*). The residual risk of behavioural impacts to blue whales/PBWs and SRWs from acoustic disturbance during the Otway Basin 3D MC MSS has been assessed as **Moderate** (*Moderate x Likely*). The residual risk of impacts to noise perception on blue whales/PBWs and SRWs from seismic sound exposure and vessel noise during the Otway Basin 3D MC MSS has been assessed as **Moderate** *(Minor x Certain).*

Based on the risk assessments for all marine receptors, the total residual risk to all BIAs within the OA from noise emissions arising from the Otway Basin 3D MC MSS has been assessed as **Low** (*Minor x Unlikely*).

7.2.2.5.3 Key Ecological Features

The OA overlaps with one KEF; the West Tasmania Canyons. The Bonney Coast Upwelling KEF lies outside of the boundaries of the OA but relatively close in proximity at 12.8 km north (see **Section 4.4.3** and **Figure 14**).

The West Tasmania Canyons KEF is recognised for its high biodiversity of benthic invertebrates and high productivity. The Bonney Coast Upwelling KEF covers the area that is annually influenced by the Bonney Upwelling which supports foraging grounds of several marine species listed within the EPBC Act (many of these species have BIAs that incorporate the Bonney Coast Upwelling KEF).

The known and potential impacts from acoustic disturbances associated with the Otway Basin 3D MC MSS on all identified marine receptors supported by the West Tasmanian Canyons and Bonney Coast Upwelling KEFs, have been discussed throughout **Sections 7.2.2.2** (potential physiological effects) and **Section 7.2.2.3** (potential behavioural effects), as well as **Section 7.2.2.4** (potential perceptual effects) together with a residual risk assessment for each receptor.

The residual risk of potential impacts on marine receptors, apart from marine mammals, arising from acoustic disturbance during the Otway Basin 3D MC MSS has been assessed as **Low.** The residual risk of potential impacts on marine mammals arising from acoustic disturbance during the Otway Basin 3D MS MSS has been assessed as **Low** – **Moderate**; however, there will be several additional control measures in place that TGS will implement when operating within the PBW and SRW BIAs and during sensitive periods for these species.

Based on the risk assessments for all marine receptors, the residual risk to the West Tasmania Canyons and Bonney Coast Upwelling KEFs arising from the Otway Basin 3D MC MSS has been assessed as **Low** (*Minor x Unlikely*).

7.2.3 Evaluation of Known and Potential Impacts to Other Marine Users

Using the information presented in **Section 4** to **Section 5**, the impact and risk assessment has been undertaken for those receptors determined to be relevant to the activity as listed in **Table 55**.

Table 82 Relevant Persons and Marine Users Assessed

Receptor	Section reference
Commercial Fisheries	**Section 7.2.3.1**
Commercial and Recreational Dive Operations	**Section 7.2.3.2**
UXOs and Defence Activities	**Section 7.2.3.3**
Cultural and Heritage Values	**Section 7.2.3.4**

7.2.3.1 Evaluation of Known and Potential Impacts and Risks on Commercial Fisheries

Increased sound levels associated with seismic acquisition may impact on target fish and invertebrate species present or adjacent to the AA, including target fish species for commercial fisheries. Based on the catch and effort data analysed by TGS, acoustic emissions have the potential to interact mainly with the CTS, SHS, Gillnet Hook and Trap Sector, SSJF, ETBF, and the long-line sector of the SBTF (see **Section 4.7.3**)..

Acoustic disturbance associated with MSSs may modify fish behaviour, and this is often observed as fish moving away from a loud acoustic source to reduce or minimise their exposure. As a result of modified fish behaviour, local abundances, distributions and, consequently, catch rates may be impacted during MSSs. This has the potential to manifest as short-term effects on catch rates within and around a survey area. However, fish behavioural responses are often observed to be temporary and short-term, with fish returning to their original area after a short period of time. For example, studies by Engås *et al.* (1996) and Slotte *et al*. (2004) have observed fish species (cod/haddock and blue whiting/herring respectively) moving back to their original areas within five days following the completion of seismic activity.

There is potential for fish in proximity to the acoustic source to modify their behaviour in areas of increased sound levels resulting from seismic operations, which may include active avoidance, schooling behaviour modification, a change in feeding patterns, or changes in local abundance and distribution within and around the area being surveyed. As noted by Salgado Kent *et al*. (2016) "*The issue of changes in commercial fisheries catch rates due to seismic surveys is almost always contentious in Australia*". They acknowledge that there has been some effort to relate fisheries catch data to seismic survey effort, but none of the Australian efforts to relate finfish catch rates with seismic surveys yielded results of any meaning.

Short-term effects on commercial and recreational catches may occur within and around a survey area. Sound effects on fishing catches are somewhat equivocal because of the lack of determination between natural movements and changes in fish. International studies have reported no significant effects of seismic activities on catch rates from a variety of taxa including crustaceans, cephalopods, teleosts, (La Bella *et al*., 1996; Jakupsstovu *et al*., 2001). Some studies have indicated that catch rates have decreased or increased following seismic activities however these changes have been reported to be temporary (Streever *et al*., 2016), and it has been suggested that the results of some studies have been influenced by a range of confounded experimental factors (Skalski *et al*., 1992; Gausland, 2003; Richardson *et al*., 2017). Where catch rates have been detected to reduce following exposure to seismic emissions a number of studies have reported that post-survey catch levels return to pre-survey levels following the cessation of seismic activities (e.g. Carroll *et al.,* 2017). Given the evidence of fish returning to survey areas following the cessation of seismic/acoustic activities, it is considered that any effects on fish and fish populations will be temporary, and fish will return to normal behaviour and distributions within days of any acoustic exposure.

For example, following a 2015 seismic survey in the Bass Strait, Przeslawski *et al*. (2016) investigated the effects of the survey on scallops, fish, and commercial catch rates. Przeslawski *et al*. (2016) found catch rates over the six months following completion of the survey were different than predicted for nine out of the 15 species within the Danish Seine and Demersal Gillnet sectors. Six species (tiger flathead, goatfish, elephantfish, boarfish, broadnose shark and school shark) increased in catch, while three species (gummy shark, red gurnard, sawshark) decreased in catch. The results of Przeslawski *et al*. (2016) support other works in which the effects of seismic surveys on catch are limited (e.g. Thomson *et* al., 2014; Bruce *et al*., 2018) and seem transitory and vary among studies, species, and gear types.

A critical review of the potential impacts of marine seismic surveys on fish and invertebrates also found that other studies on fish have positive, inconsistent, or no effects from seismic surveys on catch rates or abundance (Carroll *et al*., 2017). The body of peer-reviewed literature does not indicate any long-term abandonment of fishing grounds by commercial species, with several studies indicating that catch levels were similar to pre-survey levels after seismic activity had ceased (Carroll *et al.,* 2017). As noted by Przeslawski *et al*. (2016), it is possible that fish may be displaced from a survey footprint to adjacent areas, however, the total number of fish within the fishery stock remains unchanged.

Recently, Meekan *et al.* (2021) undertook a large-scale experiment that quantified the impacts of exposure of an assemblage of tropical demersal emperors (Lutjanidae), snappers (Lethrinidae) and groupers/rock cods (Epinephelidae) to a commercial-scale seismic source on the North West Shelf of Western Australia. The authors used a combination of Baited Remote Underwater Video Systems and acoustic tagging methods to measure the behaviours and movements of fishes at high, medium, and low exposure sites, as well as at control sites. Meekan *et al*. (2021) found no short-term (days) or long-term (months) effects of exposure on the composition, abundance, size structure, behaviour, or movement of fishes. The authors argue that it is a reasonable assumption that the behavioural responses of demersal fishes to the bait cue provided by the Baited Remote Underwater Video Systems are a realistic proxy of the likely response of the same species to baited hooks or traps used by the commercial fisheries that target them. The acoustic tags and telemetry found little evidence that fish were displaced by the exposure to the seismic source. Movements of tagged fish occurred over a limited area focused on two or three acoustic receivers, and there was no evidence for the departure of tagged fish after exposure. These multiple lines of evidence suggest that seismic surveys have little impact on demersal fishes in this environment (Meekan *et al*., 2021).

Fishwell Consulting Pty Ltd (2020) provide preliminary results from a multiple BACI analysis of the effect of a full-scale commercial 3D MSS on Danish Seine catch rates of two continental shelf species in waters off Lakes Entrance, VIC, specifically flathead (*Platycephalus* spp.) and eastern school whiting (*Sillago flindersi*). The MSS was undertaken in four phases in 2020 and preliminary results are currently published for the first three phases.

Preliminary results for whiting are reported as:

- During Phase I, zero catches comprised 7% of records in Control sites and 95% of records in Impact sites. The impact effect on whiting was estimated to be a 99.7% reduction in catch rates relative to Control Sites (this was statistically significant);
- During Phase II, zero catches comprised 14% of records in Control sites and 23% of records in Impact sites. The impact effect on whiting was estimated to be a 42.7% reduction in catch rates relative to Control Sites (this was statistically significant);
- During Phase III, zero catches comprised 16% of records in Control sites and 33% of records in Impact sites. The impact effect on whiting was between 79.5% less and 60.1% more than those from Control Sites (this was not statistically significant); and
- Overall, the BACI analyses provide robust evidence for a negative impact of seismic acquisition on whiting catch rates in the Danish Seine Fishery up to ~100 days following the MSS.

Preliminary results for flathead are reported as:

- During Phase I, zero catches comprised 2% of records in Control Sites and 22% of records in Impact Sites. The impact effect on flathead was estimated to be a 78.1% reduction in catch rates relative to Control Sites;

- During Phase II, zero catches comprised 9% of records in Control Sites and 5% of records in Impact Sites. The impact effect on flathead was estimated to be a 58.0% reduction in catch rates relative to Control Sites;
- During Phase III, zero catches comprised 20% of records in Control Sites and 25% of records in Impact Sites. The impact effect on flathead was estimated to be a 65.5% reduction in catch rates relative to Control Sites; and
- Overall, the BACI analyses provide robust evidence for a negative impact of the seismic acquisition on flathead catch rates in the Danish Seine Fishery up to ~200 days following the MSS.

The reported long-term reduction in catch of both target species by Fishwell Consulting Pty Ltd (2020) is in contrast with most other studies where impacts to fish are typically more short term (minutes, hours, days). Although the apparently statistically significant differences between impact and control sites and the reason for the effects lasting 100/200 days are notable, the shallow water exposures in the Fishwell Consulting Pty Ltd (2020) study area are not representative of those that will occur during the Otway Basin 3D MC MSS given the significantly greater water depths.

Fishwell Consulting Pty Ltd (2020) also present historical logbook data for the period 2014 to 2019, as well as the 2020 MSS, which demonstrates that catch levels of both species were already highly variable and in decline prior to the MSS. The logbook data also shows that in 2020 during and after the seismic survey, catch levels at both impact and control sites for both species were some of the lowest on record since 2014 suggesting that there may be other broader factors involved during 2020 and the study is inconclusive on this point.

Catch rates could also conceivably change in response to flow-on effects associated with changes in the abundance or distribution of zooplankton prey. As discussed in **Section 7.2.2.2.1**, a recent study by McCauley *et al*. (2017) links MSSs to zooplankton mortality, which could presumably have a negative effect on the prey availability for some pelagic fish species. However, any potential flow-on effects to marine food webs are expected to be spatially restricted to within a few kilometres of the survey vessel with baseline conditions resuming relatively quickly after survey completion (see Richardson *et al*., 2017).

In the even that commercial fishers do experience a loss in catch due to the Otway Basin 3D MC MSS, they may submit claims to TGS for compensation. The Seismic Vessel will change sail lines to accommodate commercial fishers' requests if it is feasible to do so, providing there is open and advanced communication from the commercial fishing operator of their intention to fish at a specified location, no other environmental performance commitments in this EP conflict with a change in sail lines, and providing TGS is afforded a reasonable opportunity to complete the Otway Basin 3D MC MSS in a timely and efficient manner. TGS is committed to working with relevant commercial fishers to enable fair and reasonable concurrent operations. Control measures for mitigating the effects of acoustic emissions on commercial fishers are provided in **Table 87**.

Commonwealth Trawl Sector, Scalefish Hook Sector and Gillnet Hook and Trap Sector

Most of the demersal and pelagic fish species targeted by the CTS, SHS, and Gillnet Hook and Trap sectors belong to the Group I or II hearing categories (see **Section 7.2.2.2.3.1**). As such, they are not sensitive to sound pressure and are primarily sensitive to the particle motion components of seismic discharges at relatively close range. The potential for behavioural impacts in these categories of fishes is high in the near-field (tens of metres), moderate at intermediate distances (hundreds of metres) and low in the far field (thousands of metres). Behavioural effects are noted in the relevant research to last for minutes or hours, and rarely for days following exposure.

Haddon (2017) reported on the potential effects of an MSS on commercial catch rates in the GAB trawl sector (which targets similar demersal fish species as the CTS) following 3D MSSs on the edge of the continental shelf in 2015. The author notes that the MSS may have led to the results of fishery independent surveys conducted in the area at the same time being biased low. However, the fishery independent survey results also demonstrated that catch levels can quickly recover once the MSS is over. The MSS did not have a lasting impact on catch rates, which returned to typical values within the first month following the MSS (Haddon, 2017).

A study in the Bass Strait and Gippsland Basin region of Australia, examined fisheries catch-per-unit-effort data obtained from commercial logbooks for several benthic and demersal fish species, including school whiting, tiger flathead, eastern gemfish, silver warehou, jackass morwong, blue eye trevalla, school shark and gummy shark (Thomson *et al.,* 2014). Comparison of mean catch rates for fishing operations that occurred close to and shortly after the MSS, with catch rates for fishing operations that occurred further away in both space and time, resulted in a range of different results, both positive and negative. However, the majority of these differed by less than 10%, which is a relatively small difference when compared with normal inter-annual variation. The authors concluded that there were no clear or consistent relationships between MSSs, and subsequent fisheries catch rates; however, they highlight that the coarse detail of the catch-per-unit-effort data and the variety of results meant it wasn't possible to identify if localised and short to medium-term impacts (days or weeks) to catch rates had occurred (Thomson *et al*., 2014).

A subsequent study in the same region examined catch rates for two fishing gear types (danish seine and demersal gillnet) and fifteen demersal fish species (Przeslawki *et al*., 2016; Bruce *et al*., 2018). Catch rates in the six months following the MSS were different than predicted in nine out of the 15 fish species. For both fishing gear types, six species (tiger flathead, goatfish, elephant fish, boarfish, broadnose shark and school shark) indicated increases in catch following the MSS, and three species (gummy shark, red gurnard, saw shark) indicated decreases in catch. No meaningful difference could be determined for the other six species. Bruce *et al.* (2018) noted that, except for minor changes in the daily movement patterns of flathead, there was little evidence for consistent behavioural or catch rate changes induced by the seismic survey in the targeted species. Przeslawski *et al*. (2016) concluded that "*These results support previous work in which the effects of seismic surveys on catch seem transitory and vary among studies, species, and gear types*". Though the Thomson *et al*. (2014) and Przeslawski *et al.* (2016) relates to continental shelf demersal species and a different sub-sector of the CTS, the effect on these benthic species is considered broadly indicative of species targeted on the outer shelf and slope, noting that the deeper waters in the AA, will result in lower sound levels at the seabed.

International studies that report no significant effects of MSS on catch rates include Pickett *et al*. (1994), who documented the distribution of bass in Lyme Bay (UK) during a seismic survey (peak source of 202 dB re 1 µPa@1 m) over three and a half months and found no long-term changes in bass distribution or large-scale emigrations from the survey area. In another study, Jakupsstovu *et al*. (2001) undertook a large-scale study on catch rates around the Faroe Islands and found that although many fishers perceived a decrease in catch during seismic operations, analysis of logbook records during periods with and without seismic operations showed no significant effect of seismic activity on catch rates in the area.

Løkkeborg *et al.* (2012) found that during seismic activities on a Norwegian fishing ground, catch rates changed for all species studied, except for saithe. Gillnet catches for redfish and Greenland halibut increased by 86% and 132% respectively, compared to pre-activity levels. In contrast, longline catch rates fell (16% for Greenland halibut, 25% for haddock). These varied results were explained by greater swimming activity versus lowered food search behaviour in fish exposed to acoustic emissions. Acoustic mapping of fish abundance did not suggest displacement from fishing grounds, suggesting strong habitat preference in some species (Løkkeborg *et al.,* 2012).

Some studies clearly demonstrate a reduction in catch-per-unit-effort near seismic operations. Such effects are usually temporary and localised, generally lasting from one to five days following the cessation of seismic activity. For example, Bendell (2011) analysed long-line catches off the coast of Norway during the acquisition of a two-week seismic survey with a peak source level of 238 dB re 1 µPa@1 m. Catch rates reduced by 55 – 80% within the survey area for distances up to 5 km from the active source; however, these reductions were temporary with catch rates returning to normal within 24 hours of the seismic operations ceasing. There are no studies reporting evidence of long-term displacement in commercially fished species.

In studies where reductions in catch rates occur in conjunction with MSSs, it can often be difficult to conclusively attribute a change in catch rate to the impacts of such exposure. For example, Engas *et al*., (1996) investigated the abundance and catch rates of cod (*Gadus morhua*) and haddock (*Melanogrammus aeglefinus*) in the central Barents Sea seven days before, five days during, and five days after seismic acquisition. The authors found that trawl catches of cod and haddock and longline catches of haddock declined, on average, by 50% after acquisition started and longline catches of cod reduced by 21%. Catch rates did not return to pre-survey levels during the five-day period after seismic acquisition ended. These authors hypothesised that the reduction in Atlantic cod and haddock catch rates reported from commercial longlines and trawls was most likely due to fish moving away from the seismic area (Engas *et al*., 1996); however, Skalski *et al*. (1992) argued that it may have been due to decreased responsiveness to baited hooks associated with an alarm behavioural response, or impacts related to fishing the same area for over two weeks. Some authors (e.g. Gausland, 2003) also argue that reductions in catch may represent natural fluctuations in fish stocks or long-term negative trends.

It is acknowledged that acoustic emissions from the Otway Basin 3D MC MSS may have localised and short-term effects on the behaviours of target fish species, but behaviours and catch rates are expected to return to normal shortly after the acquisition ceases. The potential extent of impacts to catch rates is unlikely to be detectable beyond the area where physical displacement of fishing vessels by the seismic vessel and towed array occurs (see **Section 7.1.3.1**). In the even that commercial fishers do experience a loss in catch due to the Otway Basin 3D MC MSS, they may submit claims to TGS for compensation (see **Table 87**).

Southern Bluefin Tuna Fishery

Given the limited hearing capabilities and sensitivity of tunas to anthropogenic noise, it is reasonable to assume that significant behavioural effects may only occur in SBT when fish are exposed to seismic acoustic emissions at relatively close ranges to the source (in the order of hundreds of metres to a few kilometres) and that any effects will be temporary and short-lived in duration (e.g hours). This is supported by observations made during the TGS Nerites Phase 1 MSS in 2014 where schools of tens or hundreds of SBT were observed within less than 1 km of an operating 4,100 cui acoustic source, displaying normal swimming and feeding behaviour at the surface, indicating limited or no long-range avoidance or change in behaviours.

Some change in distribution of juvenile SBT may also occur as a secondary effect to the disturbance of schools of sardines and other prey fish species, with the resultant localised change in distribution of prey resulting in SBT looking for prey and feeding in areas further from the area of seismic acquisition than they would do otherwise.

The SBTF consists of the purse-seine fishery and long-line fishery; only the long-line fishery has reported catch for within the AA/OA. Following catch within the purse-seine fishery, tuna are transferred to tow cages for the ranching industry which operates in South Australian waters. Divers are employed to assist with this, however, divers associated with the SBTF will not be affected by acoustic emissions from the Otway Basin 3D MC MSS on account of the distance of the AA/OA from these operations.

TGS acknowledge that acoustic emissions form the acoustic source may disturb SBT at close range. Following consultation with tuna representatives, TGS defined a SBT Assessment Area within which several additional control measures would be implemented. However, the OA has subsequently been refined, with the boundaries of the OA retracting back from the South Australian waters targeted by SBT fishers. Although the SBT Assessment Area is no longer considered to be required, several of the additional control measures that were proposed for the Otway Basin 3D MC MSS around SBT will still be adopted as standard practices. Control measures for SBT have been described in **Section 7.1.3.1.1.6** and **Table 84**.

Southern Squid Jig Fishery

Fishing effort and catch in the SSJF is highly variable and largely depends upon the demand and market price of Gould's squid. High intensity fishing effort has previously occurred to the north of the AA, offshore from Portland, in some years but not in others. Past fishing effort has also included waters off western TAS (see **Section 4.7.3.2.3**.

La Bella *et al*. (1996) looked specifically at the effect of MSSs on squid fishing catch in the central Adriatic Sea. The study concludes that no apparent changes in trawl catches were found in short-finned squid (*Illex coindetti*) the day after an MSS, where the acoustic source had a SPL of 210 dB re 1µPa, deployed at 1 m (corresponding to levels of 149 dB re 1µPa at the animals' location).

Gould's squid typically occur in water depths less than 600 m. Therefore, their distribution is limited to waters largely inshore of the 3D AA and in the 2D tie line AA. Based on the avoidance response sound exposure level of 162 dB re 1µPa^2.s reported by Fewtrell and McCauley (2012), the results of the UAM (Welch *et al*. 2023; **Appendix B**) predicts a startle response may occur between 1.05 – 2.34 km from the seismic source, when operating adjacent to areas where squid may be present, with potential increased swim speeds and avoidance over greater distances. However, any avoidance is likely to be negligible in the context of the variable distribution and natural movements of these highly mobile pelagic organisms. Therefore, impacts to catch (should fishing effort occur in the same location and at the same time as seismic acquisition) will be limited.

State-managed Giant Crab and Rock Lobster Fisheries

While the impact assessment to invertebrates predicts that there is potential for sub-lethal effects to crustaceans within 157 m and 238 m from the seismic source on the upper continental slope and along the 2D tie line respectively, the sub-lethal effects reported in studies by Day *et al*. (2016a, 2016b, 2017, 2019) on southern rock lobster included statocyst impairment and reduced tail flip/righting times. However, some of the control lobsters used in the experiments were collected from a marine reserve and were found to have a high level of pre-existing impairment to statocysts similar to that induced by the seismic exposure experiments due to long-term exposure to shipping noise. Monitoring of the lobster population at the same reserve where the lobsters with pre-existing statocyst impairment were taken from showed that the rock lobster population within the reserve was thriving and at carrying capacity and were able to climb into pots and be caught (Green and Gardner, 2009; Kordjazi *et al*., 2015).

Parry and Gason (2006) examined catch rate data for the southern rock lobster and found no significant effects of MSSs on commercial catch rates in western VIC, Australia between 1978 and 2004. During this time multiple MSSs had occurred in the area: 28 2D surveys and five 3D surveys. In this study, the number of seismic pulses was correlated to catch per unit effort data over 12 depth stratified regions. Catch per unit effort data detected no significant change in catch rates during the weeks and years following MSSs, leading the authors to conclude there was a lack of apparent impact on rock lobster fisheries from MSSs in that region.

Steffe and Murphy (1992) analysed historical catch data for king prawns before, during and after MSS operations off Newcastle, NSW, Australia. They concluded that there were no significant differences in pre-, during and post-survey catch rates and could not detect any impact on offshore prawn catches that were attributable to the MSS. However, these authors did not statistically analyse the catch data and details of the MSS (source type, source level, exposure level, exposure duration) were not provided.

Internationally, Andriguetto-Filho *et al*. (2005) found that the catch rates of the southern white shrimp (*Litopenaeus schmitti*), southern brown shrimp (*Farfantepenaeus subtilis)* and Atlantic seabob (*Xyphopenaeus kroyeri)* were unchanged during a MSS (peak source level 196 dB re 1 µPa at 1 m). These authors concluded that the results suggest that shrimp stocks are resilient to disturbance by seismic acoustic sources under experimental conditions.

Christian *et al*. (2003) found that catch rates of snow crabs (*Chionoecetes opilio*) in Newfoundland were higher following exposure to a seismic source, but noted that this was probably due to physical, biological or behavioural factors unrelated to the acoustic source.

Concerns from snow crab harvesters in Atlantic Canada that seismic noise from widespread hydrocarbon exploration was having negative effects on catch rates led Morris *et al*. (2018, 2020) to undertake a BACI study to examine the effects of industry-scale seismic exposure (2D seismic – Morris *et al.,* 2018) and 3D seismic (Morris *et al.,* 2020) on catch rates. The study area and methodology were developed following consultation with industry-based snow crab harvesters and seismic surveying industries to ensure that the study design aligned with industry standards and was realistic. Results showed no evidence of negative effects of seismic activity on catch rates over both short (within days) and longer (over weeks) time frames. Significant differences in catch rates did occur across study areas and between years; however, it was concluded that, if seismic effects on snow crab harvests did exist, the magnitude of these effects was smaller (and less important) than changes related to natural spatial and temporal influences (Morris *et al*., 2018, 2020).

The 3D AA is 510 m deep at its shallowest point, but for the most part, the northern and eastern boundaries of the 3D AA are in water depths greater than 700 m depth. The 3D AA therefore avoids the core depth range and habitat preference of giant crab (<400 m), with limited spatial overlap with the deeper limits of giant crab habitat (<820 m). Limited effects may occur in the shallowest extents of the AA, mainly limited to the single 2D tie line that may be acquired (water depth 115 m). Similarly, the AA has limited overlap with rock lobster fishing grounds; these are primarily limited to continental shelf waters, though some lobster fishing occasionally occurs in the deeper waters of the upper slope.

Due to the limited overlap with the habitat and core fishing ground for giant crab and rock lobster, and the limited effects of noise on the target species, no long-term impacts to catch rates is predicted. As a further precautionary measure, acknowledging that the TAS giant crab stock is currently assessed as Depleted, TGS propose to exclude operation of the seismic source in water depths less than 1,000 m in waters to the south of the 2D tie line AA (**Figure 74**).

Commercial Fisheries Compensation Protocol

TGS will implement a commercial fisheries compensation protocol to manage potential impacts from the Otway Basin 3D MC MSS on the commercial fishing industry in Australian waters. In the event that impacts from the Otway Basin 3D MC MSS cannot be managed or avoided, and commercial fishers experience an economic loss as a result of the Otway Basin 3D MC MSS, then financial compensation will be considered, in accordance with TGS' Commercial Fisheries Compensation Protocol. TGS' compensation protocol will be finalised prior to the Otway Basin 3D MC MSS commencing.

All claims submitted by commercial fishers[32] will be considered on a case-by-case basis. A compensation claim would only be relevant for the following occurrences:

- Interaction resulting in loss or damage to fishing equipment;
- A temporary loss of fish landed catch due to damaged or lost fishing equipment;
- Where displacement from fishing grounds results in additional costs incurred due to relocating; or
- A temporary reduction in fish landed catch due to the effects of acoustic emissions or displacement from fishing grounds. Displacement from fishing grounds can be as a result of operational activities during the Otway Basin 3D MC MSS, and as a result of avoiding contaminated waters following a fuel oil spill.

For any licence holder to be eligible for compensation, all claimants must provide notification of their intent to submit a claim within 30 days of any equipment being lost or damaged, and/or being displaced from their 'usual fishing grounds'[33]. An application form for a compensation claim will be available as part of the compensation protocol and will detail all the requirements that the claimant must address for any potential losses a licence holder may incur (as listed above). A completed compensation claim application form must be submitted to TGS within 12 months of notifying TGS of the intention to submit a claim. Claimants can provide notification of their intent to submit a claim and submit a completed compensation claim application form to otway@TGS.com.

Each completed application will be assessed to determine the merit of the claim. In doing so, consideration will be given to the circumstances giving rise to the claim, including whether the circumstances could have been reasonably avoided. TGS will communicate the outcome of the claim to the claimant (or request clarification or additional information from the claimant) as soon as practicable and within 30 days after receiving the application. If the claim is assessed to have merit, and compensation is recommended, payment will be made directly to the claimants nominated bank account within 60 days of the claim determination.

The commercial fisheries compensation protocol will apply to the waters located within the OA, and any additional area of avoidance requested around the Seismic Vessel and towed survey equipment. The commercial fisheries compensation protocol will also apply during the period of Otway Basin 3D MC MSS operations only.

Subject to a claim being lodged, TGS will, at their expense and in consultation with the claimant, engage a suitably experienced and qualified independent person or organisation[34] as the assessor to the claim. The assessor will prepare an assessment report to TGS outlining the following information:

- A copy of the letter of instruction and project brief received by the assessor (from TGS) when engaged to carry out the independent assessment;
- Conformation (or otherwise) the information provided in the claim is sufficient to conduct a meaningful assessment;
- A summary of the claim details (survey, applicant, vessel, month/s);

[32] Defined within the Commercial Fisheries Compensation Protocol as 'the entity person, licence holder, company or affected business who would have received the revenue from the landed catch that is subject of a claim under the protocol, or who can show they have incurred the cost of lost or damaged fishing gear or displacement'.
[33] Defined as '*an area where fishing activity has been recorded by the commercial fishing licence holder on government statutory fishing returns for at least two out of the previous five years*'.
[34] Defined as '*a person or organisation with proven demonstrated experience in data analysis and data auditing processes and procedures within the industry*'.

- For a loss of catch claim, monthly CPUE assessments as outlined in the commercial fisheries compensation protocol, including an estimation of any loss of catch (in kg) and its market price; and
- Any other information, comments, or views relevant to the assessment that the assessor may wish to include.

If a claimant disputes the nature of the evidence to be provided, the outcome of the claim assessment, or the payment amount, and agreement cannot be reached with TGS, the claimant may, within 30 days, request that a suitably experienced and qualified independent third-party is engaged to review and determine the outcome of the claim. The costs of engaging the independent third-party will be covered by TGS.

Summary of known and potential impacts on commercial fisheries

Overall, the effects of underwater noise during seismic acquisition are expected to have localised and short-term effects on target species. Depending on the target species, these effects may extend from a few tens of metres to a few kilometres from the source, and literature reviewed suggests affects could last for minutes, hours of days after the Otway Basin 3D MC MSS. Behavioural effects may result in some local changes to the distribution of target species, particularly mobile pelagic species. However, the resultant extent of displacement or impacts to catch levels is expected to be limited to the AA and is not broadly comparable to the area where fisheries would be displaced by the physical presence of the seismic vessel and towed equipment (**Section 7.1.3.1**).

In acknowledgement on the potential impacts of acoustic emissions on commercial fisheries that overlap with the OA/AA for the Otway Basin 3D MC MSS, TGS has developed a Commercial Fisheries Compensation Protocol whereby fishers whose catch are affected by acoustic emissions during the Otway Basin 3D MC MSS can submit a claim for compensation, to be assessed by an independent third-party assessor. This protocol will ensure that the Otway Basin 3D MC MSS is undertaken in a manner that prevents any increased cost encumbrance or loss of income to commercial fishing licence holders.

The potential overlap with commercial fisheries is considered to be negligible, such that any localised and short-term behavioural effects to target fish species at the periphery of their respective fishing grounds is not expected to have a discernible impact on catch rates; with any effects to be localised and only short-term disruptions to normal activities as well as minor adverse effects no natural resources expected. Based on available evidence, it is considered unlikely (uncommon but has been known to occur elsewhere) acoustic emissions from the Otway Basin 3D MC MSS may result in changes to commercial catches to occur. As such, the residual risk of negative impacts to commercial fishery catches due to exposure to acoustic emissions associated with the Otway Basin 3D MC MSS has been assessed as **Low** (*Minor x Unlikely*) (**Table 49**).

7.2.3.2 Evaluation of Known and Potential Impacts and Risks on Commercial and Recreational Dive Operations

Underwater, the human ear is about 20 dB less sensitive than it is in air at low frequencies (20 Hz), increasing to 40 dB at mid-frequencies (less than 1 kHz), and increasing to 70 – 80 dB less sensitive at higher frequencies (Parvin, 1998). Divers who wear neoprene hoods have even higher hearing thresholds (i.e. a lower sensitivity) above 500 Hz as the hood material absorbs high-frequency sounds (Anthony *et al*., 2010). Exposure studies related to divers have typically focused on military sonar exposure, with little information on seismic survey operations, and as such care is required when considering thresholds for non-military divers, particularly for impulsive sounds such as seismic source impulses (Ainslie, 2008).

Underwater auditory threshold curves indicate that the human auditory system is most sensitive to waterborne sound at frequencies between 400 Hz to 1 kHz (Parvin *et al*., 1994), and these frequencies have the greatest potential for damage. Within the literature (all as cited in Ainslie, 2008), there is some variation in acceptable SPLs for divers.

The auditory threshold of hearing underwater was lowest at 1 kHz (70 dB re 1 µPa SPL) and increased for lower and higher frequencies to around 120 dB re 1 µPa at 20 Hz and at 20 kHz (Parvin, 1998). Fothergill *et al*. (2000) and Fothergill *et al*. (2001) conducted controlled acoustic exposure experiments on military divers under fully controlled conditions at a US Ocean Simulation Facility and an US Open water test facility. The following exposure limit for both military and recreational divers was suggested as a conservative measure: for frequencies between 100 and 500 Hz, the maximum SPL should be 145 dB re 1 µPa over a maximum continuous exposure of 100 seconds or with a maximum duty cycle of 20% and a maximum daily cumulative total of three hours. The trading relation between the maximum SPL and duration was 4 dB per doubling of duration (e.g. 141 dB SPL for a 200 second exposure) (Pestorius *et al.,* 2009).

In alignment with these studies, and considering only frequencies between 100 and 500 Hz, Parvin (2005) suggested 145 dB re 1 µPa SPL as a safety criterion for divers. Seismic airgun sources are broadband sources, and therefore, for this assessment the most precautionary and conservative diver acoustic impact threshold is the 145 dB re 1 µPa SPL suggested by Parvin (2005). This does not imply that this level is associated with the onset of injury but represents a conservative level for protection against prolonged sound exposure for health and safety purposes.

Effects of noise on human divers range from dizziness, disorientation, temporary paralysis of limbs, or TTSs, to PTSs, severe pain, and haemorrhaging of soft tissues (Cudahy and Parvin, 2001). For sounds with frequencies of 500 – 2,500 Hz, Parvin (2005) reported temporary dizziness and related symptoms for bareheaded divers exposed to sound levels above 176 dB re 1 µPa, and vibration in forearms and thighs at sound levels above 180 dB re 1 µPa. Sounds were tolerated up to 191 dB re 1 µPa (the maximum used in the trial); however, from these results a threshold exposure level for human divers of 145 dB re 1 µPa was proposed for 100 – 500 Hz frequencies, and 155 dB re 1 µPa for 501 – 2,500 Hz.

In 2020 the Diving Medical Advisory Committee released Rev 2.1 of '*Safe Diving Distance from Seismic Surveying Operations*' Guidance Note which extended the threshold distances stated in previous revisions of the Guidance Note, with the following guidance (among others):

- Plans should be made to avoid overlapping seismic and diving activities; where this is not possible, the activities should be prioritised and a simultaneous operations plan developed;
- Where diving and seismic activity are schedule to occur within a distance of 45 km, it is good practice for all parties to be made aware of the planned activity where practicable, including clients/operators, diving and seismic contractors;
- Where diving and seismic activity will occur within a distance of 30 km a joint risk assessment should be conducted between the clients/operators involved in the seismic and diving contractors in advance of any simultaneous operations;
- The maintenance of effective communication and cooperation between the seismic vessel and the diving vessel is essential;
- Minimum safe distances should not be compromised by either party; and
- Should any diver in the water experience interference with communications, the noise level is considered to exceed acceptable exposure levels, feels sudden discomfort, or places the diver at risk in any other way, the diver's exposure should be terminated.

Diving activities in the region have been identified as recreational diving and abalone diving in coastal waters. These activities, undertaken using SCUBA or hookah equipment, are typically located in coastal waters up to 30 m depth. As outlined within **Section 4.7.2**, recreational diving will be concentrated in coastal waters at popular diving destinations such as Apollo Bay, Port Campbell, and Neptune Islands. The closest areas of coastal waters in depths diveable by recreational and abalone divers (i.e. 30 m or less) are limited to a stretch of water from Portland (VIC) to Beachport (South Australia). Based on the acoustic modelling (Welch *et al*. 2023), maximum-over-depth ranges to exceedance of the 145 dB re 1 µPa SPL criteria at modelling sites on the shelf edge off South Australia and VIC were between 12.5 and 30.2 km inshore towards coastal waters. The 30 m depth contour is over 27 km inshore of the AA, therefore the 145 dB re 1 µPa criteria is not expected to be exceeded. However, based on the guidance within the *Safe Diving Distance from Seismic Surveying Operations*' Guidance Note outlined above, as a precautionary approach, TGS will conduct a joint risk assessment and planning/mitigation between parties where diving operations will occur within 30 km, and will make all parties aware of the Otway Basin 3D MC MSS where diving and seismic activities will occur within 45 km of each other. TGS has made all efforts to consult with recreational divers that may utilise the coastal waters inshore of the OA (see **Section 5**).

Offshore oil and gas installations are typically noisy above and below water; therefore, commercial divers working around the offshore facilities are already exposed to high levels of noise (Anthony *et al*., 2010). Dive operations at these installations are routinely carried out for inspection and maintenance works and may occur while the Otway Basin 3D MC MSS is operating. The closest producing field from the AA is the Thylacine Platform, approximately 8 km from the AA (and within the OA). Installation operators will be kept updated throughout the programme with the 48-hour look-ahead so that they may schedule any dive operations as they deem appropriate to ensure the safety of their divers as they undertake their own risk assessment as part of their diving procedures. TGS will be in regular contact with gas installation operators who will be able to schedule dive operations as they deem appropriate.

TGS has undertaken an extensive consultation programme during the preparation of the EP and has identified several dive operators that are of relevance to the Otway Basin 3D MC MSS including recreational and commercial (petroleum operators and abalone fishers) dive operators (**Section 5**). To date, there have been no concerns raised by recreational fishers with regard to dive operations. Commercial abalone divers have raised concerns regarding the potential effects of seismic emissions on abalone habitat, but not concerns for divers in the water. Due to the distance offshore of the OA from dive-able abalone habitat (<30 m), there will be no effects of acoustic emissions on abalone habitats or abalone divers. Full correspondence is provided in **Appendix H**.

Based on the above, and the control measures in place (**Table 84**), the potential residual risk to divers from noise emissions during the Otway Basin 3D MC MSS has been assessed as **Low** (*Rare x Minor*).

7.2.3.3 Evaluation of Known and Potential Impacts to UXOs and Defence Activities

The OA covers four areas identified by the Department of Defence as containing UXOs: SDG110, SDG136, SDC006, and 1052 (**Figure 70**). These areas were used for the dumping at sea of ammunition (including detonators and explosives), chemical munitions, and as an air-to-air firing range. SDC006 is of note as a dumping area for chemical munitions, i.e. mustard gas.

During World War II, Australia held stocks of Chemical Warfare Agents (**CWA**) to be used in retaliation to CWA used by the Japanese. None of the stockpiled CWA munitions were used during combat, leading to the need for disposal of CWAs. "*Drowning at sea at 500 fathoms (915 m)*" was determined to be the only feasible method of destruction (Plunkett, 2003) as disposal at sea was considered to be safe and convenient (Greenberg *et al*., 2016). Evidence suggests that most of Australia's CWA stocks were disposed of in this manner (Plunkett, 2003). It is considered that most of the disposed CWA material will have sunk close to the dump position where it would be buried by sediment or encrusted by marine organisms; however, due to surrounding currents there would have been some drift of lighter material away from the dump site. Some UXO may also no longer exists, having fully dissolved, rotted, or corroded (Plunkett, 2003).

Over time, the cylinders within which the UXOs were disposed are known to corrode, releasing the contained CWA into the surrounding marine environment. For example, in the 1950s, severe metal corrosion was evident in recovered munition casings a few years after dumping at sea had occurred (Greenberg *et al*., 2016), and WWII munitions that had been disposed of in the Baltic Sea and subsequently netted by fishermen between 2000 and 2005 were completely corroded (HELCOM, 2005). Corrosion rate will, however, be site specific due to differing environmental variables.

Although the water solubility of mustard gas is relatively low, dissolved components rapidly hydrolyse to form thiodiglycol and thioxane, with the formation of intermediate sulphur compounds in small amounts (Munro *et al*., 1999). Thiodiglycol is the most toxic degradation by-product and is a mild irritant with low acute and chronic toxicity potential (Reddy *et al*., 2005; Bizzigotti *et al*., 2009). Over time, mustard gas exposed to ocean water forms a solid concretion, with an outer polymer crust of intermediate breakdown products which increases its persistence in the marine environment (Munro *et al*., 1999); however, various environmental variables aid breakdown such as higher temperatures, water flow, and mechanical disruption (i.e. movement along the sea floor) (Greenberg *et al*., 2016). There are several naturally occurring sediment microorganisms that can break down CWAs (Medvedeva *et al.,* 2009), this biodegradation further enhances the breakdown of these materials and the removal of the toxic components (Sanderson *et al.,* 2010). These microbes can mineralise the degradation by-products even at low temperatures; hence they are thought to contribute significantly to dumpsite decontamination (Medvedeva *et al*., 2009). Furthermore, microbial action typically reduces the timescale over which CWAs are considered to be an environmental threat to <100 years (probably closer to 50 years); by which time the toxic components are expected to be significantly hydrolysed and mineralised (Sanderson *et al*., 2010).

Despite the high volumes of CWAs dumped worldwide, there is a paucity of information on the aquatic toxicity of mustard gas and its degradation products (Czub *et al*., 2020), although direct contact with mustard gas is known to be toxic for humans, terrestrial mammals, and fish (Czub *et al.,* 2020). Evidence suggests that it rapidly penetrates cells and (via damage to DNA, RNA and proteins) affects a variety of cell functions (Papirmeister *et al.*, 1991). Lang *et al*. (2014) investigated the health of cod (*Gadus morhua*) at CWA dumpsites in the Baltic Sea and concluded that there was no indication of significant generic health effects in cod from dump sites compared to reference sites, although fish communities within the dump site were regarded as stressed. In contrast, Stock (1996) stated that mustard gas has no significant effects on fish and fish do no bioaccumulate this agent (as described in Plunkett, 2003).

Acoustic sources produce short duration, predominantly low frequency noise with high peak source levels. The acoustic pulse forms a steep-fronted wave that is transformed into a high-intensity pressure wave. This pressure wave is essentially a shock wave with an outward (i.e. horizontal) flow of energy in the form of water movement. In addition to this horizontal pressure wave, the sea floor directly underneath the active seismic source will be subject to both the downward going incident signal and its upward going reflection from the seafloor (Duncan, 2016).

While little information is available about how pressure levels impact solid structures on the seafloor, research indicates that soft bodied benthic organisms directly in the path of an active seismic survey are largely unaffected by exposure at a cellular level. For example, Carrol *et al*. (2017) conducted a comprehensive literature review of the potential impacts of low-frequency seismic sound on the physical and physiological attributes or marine organisms and reported no tissue or organ damage for bivalves or fish at either realistic or unrealistic seismic exposures. It is reasonable to assume that solid objects on the seafloor, such as the munition casings dump sites, will be substantially more robust to exposure than living organisms and would therefore be unlikely to sustain any damage on account of the acoustic pressure waves generated during marine seismic surveys.

It is noteworthy that seismic surveys are often used to map the underlying substrate of the seafloor in areas where submerged pipelines exist (e.g. in producing oil and gas fields). Indeed, Sanderson *et al*. (2010) conducted extensive seismic mapping of the largest CWA dumpsite in the Baltic Sea (in water depths of 70 – 96 m) as part of a study into the potential environmental effects of legacy contaminants which were dumped following WWII.

The potential for seismic emissions to damage the casings containing the mustard gas was raised during consultation with relevant persons, therefore, as a precautionary control measure around UXOs, TGS will implement an Acoustic Exclusion Area of 3 NM around the centre point of UXO site SDS006 within which there will be no activation of the acoustic source (**Figure 84**). This site was an area of chemical munitions dumping (mustard gas).

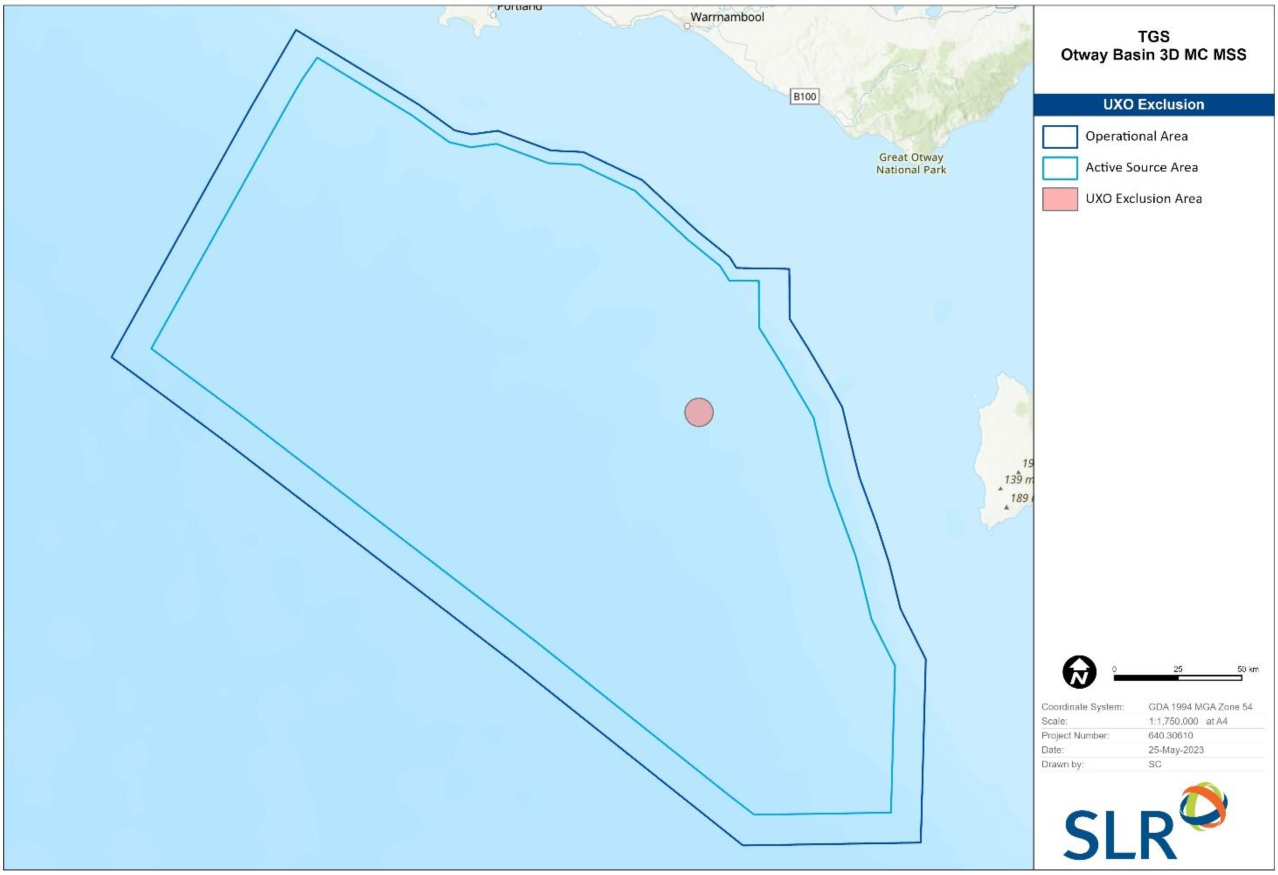

Figure 84 UXO SDS006 Acoustic Exclusion Area

TGS has consulted with the Department of Defence as a relevant person throughout the preparation of this EP who advised that part of the proposed OA is located within the South Australian Exercise Area and restricted airspace, and that UXO may be present on the seafloor. It was advised that all activities are conducted at TGS' own risk, and that the Commonwealth of Australia takes no responsibility for reporting the location and type of UXO that may be in the area, identifying or removing any UXO from the area, and any loss or damage suffered or incurred by TGS or any this part arising out of, or directly related to UXO in the area.

In order to ensure that activities associated with the Otway Basin 3D MC MSS, TGS will provide ongoing notification of activities prior to and during the Otway Basin 3D MC MSS and will ensure that any activities undertaken within the restricted airspace comply with the Notice to Airmen restrictions, including liaison with the airspace controlling agency if restricted airspace is activated (e.g. during periodic aerial surveys).

Based on the above, the residual risk to UXO and defence activities arising from acoustic emissions during the Otway Basin 3D MC MSS has been assessed as **Low** (*Minor x Remote*).

7.2.3.4 Evaluation of Known and Potential Impacts to Heritage Values

TGS has identified four shipwrecks within the OA (**Figure 46**) that will be subject to acoustic emissions during the Otway Basin 3D MC MS. MSSs are regularly utilised to detect and map the extent of shipwrecks in the marine environment (e.g. Ward *et al.,* 1999; Grøn *et al*., 2015) and as a result there will be no impacts to the identified shipwrecks as a result of acoustic emissions from the Otway Basin 3D MC MSS.

The residual risk to heritage values (i.e. shipwrecks) arising from acoustic emissions during the Otway Basin 3D MC MSS has been assessed as **Negligible** (*Negligible x Rare*).

7.2.4 Decision Context

The decision context for Acoustic Disturbance to the Marine Environment has been assessed as Type B, although the uncertainty is minimal, given the greater complexity associated with the predicted impacts and risks. The level of interested raised by relevant persons regarding predicted impacts to commercial fisheries, marine mammals and protected areas is consistent with this characterisation.

7.2.5 Identification of Control Measures, Residual Risk Assessment and Demonstration of ALARP

The control measures that will be implemented during the Otway Basin 3D MC MSS to manage the impacts from acoustic disturbance to **ALARP** have been included in **Table 84**. TGS has considered a number of control measures to determine the benefits of their implementation towards risk reduction (**Table 84**), based on a Hierarchy of Controls methodology **Table 83**). The control measures that will be adopted are those that have been assessed and characterised as effective and practicable to implement.

Table 83 Hierarchy of Control Measures for Acoustic Disturbance to the Marine Environment

Eliminate	Noise emissions are a fundamental requirement of any MSS in order to produce the detailed geological images and meet survey objectives. As a result, noise emissions cannot be eliminated.
Substitute	Alternative data acquisition methods are not yet commercially available or proven to meet geophysical data quality objectives, operational safety, and reliability requirements. Therefore, no practicable substitutes are available.
Reduce	The maximum capacity of the acoustic source has been designed to be as low as possible while still maintaining the ability to meet survey objectives. Survey operations will run 24/7 (where possible) to reduce the total duration of the Otway Basin 3D MC MSS. The acoustic source will not be operated in waters outside of the OA, and deployment and retrieval of the acoustic source will only occur within the bounds of the OA to ensure there is no accidental discharge of the acoustic source outside of the OA.
Mitigate	Control measures have been assessed within **Table 84** in order to mitigate the impacts from noise emissions to **ALARP** levels. Those which are appropriate and are not impracticable or unfeasible (**Table 84**) will be implemented for the duration of the Otway Basin 3D MC MSS.

Table 84 Assessment of Control Measures for Managing the Acoustic Disturbance to the Marine Environment

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Legislative Requirements:			
The Otway Basin 3D MC MSS will be undertaken in accordance with the approved EP.	P = Yes E = Effective	All vessels undertaking an offshore activity in waters between 3 and 200 NM must undertake that activity in line with an approved EP. The approved EP outlines the measures that will be taken to ensure that environmental effects from the activity will be reduced to **ALARP** and **Acceptable Levels**, including the management of routine permissible waste discharges.	Yes
Adherence to Policy Statement 2.1 requirements, through the implementation of the following control measures with respect to all whales (baleen and toothed), throughout the entire OA for the duration of the Otway Basin 3D MC MSS: • Observation zone[AC 35]: 5+ km horizontal radius from the acoustic source; • Shut-down Zone[AC]: 2 km horizontal radius from the acoustic source; • Crew training: Crew are trained in the basic requirements of Policy Statement 2.1 prior to the survey commencement and will also be familiar with the commitments in this EP; • Pre-start-up Visual Observations (daylight hours): 30 minutes prior to the commencement of Soft-start Procedure; • Soft-start Procedure: Commences only where no whales have been sighted within Shut-down Zone over a 30 minute Pre-start up Visual Observation period; • Start-up Delay Procedures: Will be implemented if a whale enters the Shut-down Zone during the soft-start; • Stop Work Procedures: Will be implemented whenever a whale is detected in the Shut-down Zone; • Night-time and Low Visibility Procedures: Will be implemented throughout periods of low visibility, including night-time, under rough seas or fog; • Compliance and Sighting Reports.	P = Yes E = Effective	Adherence to Policy Statement 2.1 is a legislative requirement. Further detail regarding the suite of control measures to be adopted in accordance with Policy Statement 2.1 has been provided below and within **Appendix M**. Note that the use of a 5+ km Observation Zone goes above and beyond the requirements of the standard management procedures outlined in Policy Statement 2.1. In the case of the Otway 3D MSS, an extension to the Observation Zone is warranted because of the high likelihood of encountering whales during the proposed survey. The distance of 5 km was selected on the basis that blue whale detection can be reasonably expected to 5 km over a range of sighting conditions, and several other whale species will be visible over this range (e.g. southern right whales, humpback whales, sperm whales, fin whales, sei whales). The use of a 2 km Shut-down Zone also goes above and beyond the requirements of the standard management procedures outlined in Policy Statement 2.1. Additional controls presented within the Legislative Requirements section, to assist in understanding the implementation of the total suite of whale management measures, are marked with AC superscript (e.g., control[AC]).	Yes
Policy Statement 2.1: Precaution Zones: • Observation Zone[AC]: 5+ km horizontal radius from the acoustic source; • Extended Observation Zone for BW/PBW and SRWs; • Shut-down Zone[AC]: 2 km horizontal radius from the acoustic source; • An Extended 7 km Shut-down Zone[AC] for BW/PBW and SRWs; and Shutdown at any distance for a SRW mother-calf pair.	P = Yes E= Effective	Precaution Zones are set based on the likely sound levels surrounding the acoustic source as demonstrated by acoustic modelling. The use of Precaution Zones provides the basis for the mitigation measures throughout Policy Statement 2.1 and defines the zones where certain operational procedures will be implemented (e.g. shut-downs of the acoustic source when a whale enters/is sighted within the Shut-down Zone). In addition to the standard Precaution Zones prescribed within Policy Statement 2.1, for surveys exceeding received sound exposure levels of 160 dB re 1 µPa, additional Precaution Zones have been applied to protect PBW, SRW and 'other whales' based on the outputs of UAM or Animat modelling. The justification for additional Precaution Zones is further described in **Appendix M.** Additional Precaution Zones that will be implemented during the Otway Basin 3D MC MSS include: • Observation Zone[AC]: 5+ km horizontal radius from the acoustic source; • An Extended Observation Zone[AC] for BW/PBW and SRWs; • An Extended 2 km Shut-down Zone[AC] for 'other whales'; • An Extended 7 km Shut-down Zone[AC] for BW/PBW and SRWs; and • Shutdown at any distance for a SRW mother-calf pair. It is a legislative requirement to adopt this control measure; environmental benefit outweighs additional cost.	Yes

[35] Additional controls presented within the Legislative Requirements section, to assist in understanding the implementation of the total suite of whale management measures, are marked with AC superscript (e.g., control[AC]).

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Policy Statement 2.1: A.2 – Crew training (General crew).	P = Yes E= Effective	Vessel crew are required to have sufficient training in order to implement the mitigation procedures of Policy Statement 2.1. TGS will ensure that all crew are trained to understand the basic requirements of Policy Statement 2.1 and the specific Precaution Zones that will be implemented as part of the Otway Basin 3D MC MSS. Crew will be informed that they have a responsibility to report any opportunistic marine mammal sightings that they may make to an on-duty MFO. At the start of the survey a briefing will be provided to all crew on board all survey vessels on environmental matters, including information on Policy Statement 2.1, whale identification and the environmental legal obligations for companies operating in Australian waters. This will constitute an environmental induction on the EP and it's requirements. Reference material will be provided and made available for the duration of the survey onboard all survey vessels, including Policy Statement 2.1, the Department's Whale and Dolphin sighting report form and the APPEA CD Guide 'Search Australian Whales and Dolphins'. Appropriate visual aids such as binoculars will be available on board each survey vessel to aid in the identification and reporting of any marine mammals sighted. The MFOs will have primary responsibility for whale observation and compliance with the Precautionary Zones; however, trained crew will act in a support role by immediately reporting any opportunistic marine mammal sighting (from either the Seismic Vessel or any of the support vessels) to the on-duty MFO, and by assisting the MFO with any duties as requested. Legislative requirement to adopt control measure; environmental benefit outweighs additional cost.	Yes
Policy Statement 2.1: A.3.1 – Pre-start-up visual observations procedures. The 5+ km Observation Zone[AC] will be monitored for the presence of whales for at least 30 minutes before the commencement of a Soft-start Procedures.	P = Yes E= Effective	Pre-start up visual observations are required under Policy Statement 2.1. An Observation Zone[AC] of 5+ km will be monitored from the Seismic Vessel. The 5+ km Observation Zone[AC] will be monitored for the presence of whales for at least 30 minutes before the commencement of a Soft-start Procedure. The dedicated, trained, and experienced MFOs on both the Seismic Vessel and the Attending Support Vessel will have direct responsibility for undertaking pre-start-up visual observations and compliance with the Precautionary Zones, with trained crew (see above) support as required. Legislative requirement to adopt control measure; environmental benefit outweighs additional cost.	Yes
Policy Statement 2.1: A.3.2 – Soft-start procedures. Limits on when soft start procedures can commence will be applied for the duration of the survey as follows: • If no acquisition has occurred in the preceding 24 hours, soft starts may only commence in daylight hours and when conditions allow visual inspection of the 5+ km Observation Zone[AC]; • If acquisition has occurred within the preceding 24 hours and no whale initiated shut-downs have been made during this period, then soft starts may commence at night or during periods of low visibility providing they occur outside of the BW BIAs/buffer and the SRW Ag BIA/buffer.	P = Yes E= Effective	Soft Start Procedures are a gradual increase of power over a set period with the intention of allowing adequate time for whales to leave the area before being exposed to the highest sound levels (Wright and Cosentino, 2015). They will also alert other marine fauna and allow them time to move away from the active source, avoiding potential physiological impacts. Soft-starts over a period of 30 minutes are a requirement of Policy Statement 2.1, where their implementation allows the power of an acoustic source to be gradually increased prior to the survey commencing which ensures that any whales that go undetected during pre-start-up observations have an opportunity to leave the vicinity of the acoustic array before full operational power is reached. The commencement of soft start procedures will be limited depending on whether or not acquisition occurred in the preceding 24 hours. If acquisition has occurred during this timeframe and no whale instigated shut downs were made, then soft starts may occur at night or during periods of low visibility providing they occur outside of the BW BIAs/buffer and the SRW Ag BIA/buffer. This provision is adopted on the basis that prior acquisition without sightings is indicative that the likelihood of whales going undetected in poor sightings conditions (night/low visibility) is low. However, if no acquisition occurred in the preceding 24 hours, then a more precautionary approach is warranted and soft starts may only commence in daylight hours and when conditions allow visual inspection of the 5+ km Observation Zone[AC.] Legislative requirement to adopt control measure; environmental benefit outweighs additional cost.	Yes

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Policy Statement 2.1: A.3.3 – Start-up delay procedures.	P = Yes E= Effective	During Soft-start Procedures in daylight hours, at least one MFO will be stationed on the bridge of the Seismic Vessel undertaking continuous visual observations for whales. If a whale enters a relevant Shut-down Zone (i.e., 7 km for BW/PBW and SRW; and 2 km for all 'other whales'), the acoustic source will be immediately shut-down. If the acoustic source is shut-down for an 'other whale' species, a soft-start procedure will only resume after the whale has been observed to move outside the 2 km Shut-down Zone[AC], or when 30 minutes has lapsed since the whale was last sighted within the Shut-down Zone. If the acoustic source is shut-down for a BW/PBW or SRW a soft-start procedure will only resume after the whale has been observed to move outside the 7 km Shut-down Zone[AC], or when 30 minutes has lapsed since the last BW/PBW or SRW sighting. The intention of these delays is to allow sufficient time for any whale/s to exit the Precaution Zones and avoid exposure to the highest sound levels. Start-up delays are a requirement of Policy Statement 2.1. Legislative requirement to adopt control measure; environmental benefit outweighs additional cost.	Yes
Policy Statement 2.1: A.3.5 – Stop work procedures. Stop work procedures will be implemented when: • Any 'other whale' enters or is detected in the Extended 2 km Shut-down Zone[AC;] • A BW/PBW enters or is detected in the Extended 7 km Shut-down Zone[AC]; • A SRW enters or is detected in the Extended 7 km Shut-down Zone[AC]; or • MFOs onboard the Seismic Vessel or the attending support vessel detect a SRW mother-calf pair at any distance.	P = Yes E= Effective	Stop work procedures are a requirement of Policy Statement 2.1. Stop work procedures will be implemented when: • Any 'other whale' enters or is detected in the Extended 2 km Shut-down Zone[AC;] • A BW/PBW enters or is detected in the Extended 7 km Shut-down Zone[AC]; • A SRW enters or is detected in the Extended 7 km Shut-down Zone[AC]; or • MFOs onboard the Seismic Vessel or the attending support vessel detect a SRW mother-calf pair at any distance. This control measure will be implemented by dedicated, trained and experienced MFOs that will be onboard the Seismic Vessel and Attending Support Vessel for the duration of the Otway Basin 3D MC MSS. After any 'other whale' has been observed to have left the Shut-down Zone or has not been detected for 30 minutes, start-up procedures can commence again. Following BW/PBW and SRW shut-downs, vessel relocation is required before start-up procedures can recommence. The details of these relocation requirements are provided later in this table where the specific controls for these species are described. Legislative requirement to adopt control measure; environmental benefit outweighs additional cost.	Yes
Policy Statement 2.1: A.3.6 – Night-time and low visibility procedures. During these periods, operations may proceed provided there have not been three or more whale instigated power-down or shut-downs during the preceding 24-hour period. Commencement of soft-start procedures at night or during periods of low visibility will be limited to circumstances when: • Acquisition has occurred within the preceding 24 hours and no whale initiated shut-downs have been made during this period; and • May only occur outside of the BW BIAs/buffer and the SRW Ag BIA/buffer. The following additional criteria in relation to BW/PBW or SRW shut-downs must also be satisfied before night time and low visibility operations can occur: • Low Visibility or Night-time Operations may occur provided that no BW/PBW shut-downs have been instigated during the preceding 24 hours within 32 km of the planned acquisition (i.e. the survey lines that will occur during the hours of darkness or the period of low visibility).[AC] • Low Visibility or Night-time Operations may occur provided the no SRW shut-downs have been instigated during the preceding 24 hours within 42 km of the planned acquisition (i.e. the survey lines that will occur during the hours of darkness or the period of low visibility).[AC]	P = Yes E= Effective	Specific night-time and low visibility procedures are a requirement of Policy Statement 2.1. They allow the MSS to continue throughout periods of reduced/low visibility (e.g. night-time, or periods of rough seas or fog). During these periods, operations may proceed provided there have not been three or more whale instigated power-down or shut-downs during the preceding 24-hour period. Generally speaking, TGS has adopted the threshold of three or more whales based on what was recommended within Policy Statement 2.1 Standard Management Procedures. However, given the proximity to the BW BIAs and the SRW Ag BIA, a more conservative threshold has been set for these species, and additional controls regarding the commencement of soft start procedures at night or during periods of low visibility will also apply[AC]. Legislative requirement to adopt control measure; environmental benefit outweighs additional cost.	Yes

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Policy Statement 2.1: A.4 – Compliance and Sighting Reports. All cetacean sightings will be recorded in the 'Cetacean Sightings Application' software.	P = Yes E= Effective	A report on the conduct of the Otway Basin 3D MC MSS and any whale interactions will be provided to the DoEE within two months of survey completion following the minimum content recommendations in Policy Statement 2.1. All cetacean sightings will be recorded in the 'Cetacean Sightings Application' software. Legislative requirement to adopt control measure; environmental benefit outweighs additional cost.	Yes
Good Practice			
The minimum source size to acquire the survey data and meet the geophysical objectives of the Otway Basin 3D MC MSS has been selected. The acoustic source size used will not exceed that which has been modelled (3,480 in^3) and for which the predicted impacts and risks have been assessed. If the source used for the Otway Basin 3D MC MSS differs to that modelled in the EP, additional modelling will be undertaken.	P = Yes E = Effective	The acoustic source volume has been intentionally selected as it is considered to be the minimum source size identified to meet the geophysical objectives of the survey, taking into account the water depth, the depth of the geophysical targets and the properties of the underlying geology The sound propagation which will arise as a result of the acoustic source generation has then been modelled. The outcomes of this modelling are required to inform the environmental impact and risk assessment and ensure the activity is adequately managed. The maximum modelled zero to peak sound pressure level from the triple 3,480 in^3 acoustic source will be 258.3 dB re 1 µPa @ 1 m. If the acoustic source used for the Otway Basin 3D MC MSS differs to that modelled in the EP (i.e. within Welch *et al*., 2023, **Appendix B**), additional modelling will be undertaken prior to the commencement of the Otway Basin 3D MC MSS to confirm that the far-field horizontal source level specifications of the selected seismic source are consistent with those assessed in the EP and that the control measures and EPSs adopted for the Otway Basin 3D MC MSS are appropriate and manage potential impacts to ALARP and Acceptable Levels. Changes will be documented as per the Management of Change requirements. Good industry practice, environmental benefit outweighs additional cost.	Yes
Towed equipment will be retrieved when the Seismic Vessel is in transit to and from the OA (e.g. to and from port).	P = No E =Effective	Retrieval of towed equipment would reduce the potential for more coastal species interacting with the towed equipment whilst in transit and will minimise the spatial footprint of the Seismic Vessel when transiting; however, the Seismic Vessel may on occasion be required to exit the OA without retrieving the towed equipment, such as during periods of inclement weather. Not practicable to implement.	No
The acoustic source will only be deployed and retrieved within the bounds of the OA.	P = Yes E = Effective	As outlined above, there may be occasions during the Otway Basin 3D MC MSS whereby the vessel may be required to exit the OA while towed equipment remains deployed. In order to ensure there is no accidental discharge of the acoustic source outside of the boundaries of the OA, the acoustic source will only be deployed and retrieved in the OA.	Yes
A communications protocol will be in place between the survey vessels and other relevant persons (e.g. commercial fishers known to utilise the OA, oil and gas operators), to actively manage concurrent activities.	P = Yes E =Effective	A communications protocol will be in place which details the methods used to contact third-party vessels prior to commencement of the Seismic Survey, throughout the survey duration, and following completion of the survey, and those identified only once at sea, to actively manage concurrent activities. Communication with relevant persons allows those potentially affected by the Otway Basin 3D MC MSS to plan activities in a manner that reduces the risk of interactions with the survey vessels and towed equipment (e.g. commercial fishers can avoid deploying gear in the path of the Seismic Vessel). TGS will provide a daily 'look-ahead' plan, which details the proposed operations for the next 48-hour period. Information regarding proposed operations will include, as a minimum, the current positions of the survey vessels and the proposed timing and location of operations for the following 48-hour period. These will be provided daily to those relevant persons who register for the service. As part of this communication, TGS will request information from commercial fisheries on upcoming fishing activities for the next 24 – 48 hours. This will allow the Seismic Vessel to consider alternative lines, where practicable. The Seismic Vessel will change sail lines to accommodate commercial fishers' requests if it is feasible to do so, providing there is open and advanced communication from the commercial fishing operator of their intention to fish at a specified location, no other environmental performance commitments in this EP conflict with a change in sail lines, and providing TGS is afforded a reasonable opportunity to complete the Otway Basin 3D MC MSS in a timely and efficient manner. This control measures have been proposed in response to consultation with relevant persons. Good industry practice, safety benefit outweighs additional cost.	Yes
Publication of a Notice to Mariners confirming the Otway Basin 3D MC MSS will proceed, no less than four weeks before operations commence.	P = Yes E = Effective	Under the Navigation Act 2012, AHO can publish and distribute a Notice to Mariners. This Notice outlines potential hazards and restrictions to other marine users. The notice will be published no less than four weeks before operations commence.	Yes

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
		Good industry practice, safety benefit outweighs additional cost.	
Where the potential for concurrent MSSs to occur is identified, TGS will engage with proponents prior to commencing the Otway Basin 3D MC MSS and develop a SIMOPS plan. SIMOPS planning will include the implementation of a 40 km spatial separation between the Seismic Vessel and any other operating Seismic Vessel in the Otway Basin area.	P = Yes E = Effective	Multiple MSSs operating simultaneously in close proximity to each other would potentially increase the spatial extent of acoustic energy and the intensity of acoustic energy (if acoustic areas overlap). Spatially separating concurrent MSSs reduces the potential for cumulative noise impacts, through limiting sound source levels to those associated with a single acoustic source. Engagement with proponents prior and development of a SIMOPS plan will include the following: • Communications protocol • Work programming • Hazard management • Emergency Response Good industry practice, environmental benefit outweighs additional cost.	Yes
Compensation to fishers and vessel crews (i.e., the claimant) is demonstrated to have occurred for the following circumstances: • Interaction resulting in loss or damage to fishing equipment; • A temporary loss of fish landed catch due to damaged or lost fishing equipment; • Where displacement from fishing grounds results in additional costs incurred due to relocating; or • A temporary reduction in fish landed catch due to the effects of acoustic emissions or displacement from fishing grounds. Claims received from fishers in any circumstances other than those outlined above will not be assessed. Claims will be considered provided the interaction/displacement/loss of catch took place in the Adjustment Area (plus any additional area of avoidance requested around the survey vessels and towed equipment) where the Otway Basin 3D MC MSS took place, and within the project active time frame only.	P = Yes E = Effective	Where impacts of the Otway Basin 3D MC MSS to the commercial fishing industry in Australian waters cannot be avoided or minimised, and commercial fishers experience an economic loss as a result of the Otway Basin 3D MC MSS, financial compensation will be considered as a potential appropriate response to eligible fishery licence holders. Compensation to commercial fishers for loss or damage to fishing equipment, a temporary loss of fish landed catch due to damaged or lost fishing equipment, where displacement from fishing grounds results in additional costs incurred due to relocating, or a temporary reduction in fish landed catch due to effects of acoustic emissions of displacement from fishing grounds that is proven to have occurred as a result of the Otway Basin 3D MC MSS will be considered on a case-by-case basis. Claims received from fishers in any circumstance other than these will not be assessed. Displacement from fishing grounds can be as a result of seismic operational activities and/or as a result of avoiding contaminated waters following a fuel oil spill. For TGS to accept a payment claim, fishers will need to provide suitable documented evidence and data to demonstrate their unavoidable economic loss in accordance with the Commercial Fisheries Compensation Protocol for the Otway Basin 3D MC MSS (**Section 7.2.3.1**). All fishing history and unavoidable economic losses should relate to the Adjustment Area and to the period of Otway MSS operations. The Adjustment Area is defined as an area extending 10 km around the perimeter of the OA. Any consideration of claims (for claims for temporary reduction in catch due to displacement from fishing grounds) beyond the Adjustment Area and outside the operations period will be determined with reference to available and relevant peer reviewed information on the effects of seismic surveys, as well as the impact assessment outlined in the EP as accepted by NOPSEMA. To be eligible for compensation, claimants are required to provide initial notification of their intent to submit a claim to TGS within 30 days of equipment being damaged or lost, and/or being displaced from 'usual fishing grounds' (defined as an area where fishing activity has been recorded by the commercial fishing licence holder on Government statutory fishing returns for at least two of the previous five years). For displacement claims only, licence holders or vessels are to notify TGS at the time of relocation for claims to be valid. A completed Compensation Claim Application Form must be submitted to TGS within 12 months of notifying TGS of the intention to submit a claim. In assessing the merit of the claim, consideration will be given to the circumstances giving rise to the claim, including whether the circumstances could have been reasonably avoided. Subject to a claim being lodged, TGS (at their expense) in consultation with the claimant, will engage a suitably experienced/qualified independent person/organisation as the assessor of the claim, defined as a person or organisation with proven demonstrated experience in data analysis and data auditing processes and procedures within the industry. The assessor will provide TGS with an assessment report, which, upon receiving and considering this report, TGS will provide to the claimant and offer to meet to discuss and address the claim. If a claimant disagrees with the claim assessment outcome and cannot reach agreement with TGS, they may, within 30 days, opt to request a suitably experienced and qualified independent third-party to review and determine the outcome of the claim. This appointment will be mutually agreed between TGS and the claimant. The dispute will be resolved within 60 days of dispute receipt by TGS, with the costs of engaging the independent third-part covered by TGS.	Yes

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
		Good industry practice, socio-economic benefits outweigh additional cost.	
Notification to recreational and commercial divers that are undertaking diving activities within 45 km of the acoustic source.	P = Yes E = Effective	Guidance note DMAC 12 issued by the DMAC "*Safe Diving Distance from Seismic Surveying Operations* recommends that where diving and seismic activity occur within 30 km of each other, a joint risk assessment should be conducted. Where diving and seismic activities occur within 45 km of each other, all parties should be made aware of the planned activity. Good industry practice, safety benefit outweighs additional cost.	Yes
A joint risk assessment will be conducted with recreational and commercial divers where their respective diving activities may occur within 30 km of the acoustic source.	P = Yes E = Effective	Guidance note DMAC 12 issued by the DMAC "*Safe Diving Distance from Seismic Surveying Operations* recommends that where diving and seismic activities occur within 30 km of each other, a joint risk assessment should be undertaken. Good industry practice, safety benefit outweighs additional cost.	Yes
Alternatives/Substitutes Considered			
Elimination of noise emissions from the acoustic source.	P = No E = Very Effective	Noise emissions are a fundamental requirement of any MSS in order to produce the detailed geological images and meet survey objectives. As a result, noise emissions cannot be eliminated.	No
Use of alternative seismic sound sources and alternative geological imaging technology.	P = No E = Unknown Effectiveness	Alternative technologies such as 'eSource' and 'e-seismic' have been considered. These technologies are relatively new technologies that have been designed to limit the component of sound levels at frequencies higher than then frequencies essential for seismic exploration. Presently, however, there is only one vessel globally with the eSource capability and is it currently impossible to commit to a single seismic operator at this stage. To replace or update the seismic array on another vessel would cost in the order of US$2 million for the new hardware. Marine vibroseis is another emerging technology that may reduce sound output. This technology has been designed to release the same amount of energy as a standard airgun array, but rather than releasing high-magnitude impulses, energy is release continuously or intermittently for al longer period of time. Instantaneous physiological effects (e.g. injury) ranges, such as those typically represented by the single impulse metrics may be reduced, however, cumulative sound exposures (which result in the greatest effects ranges for marine mammals and most other environmental receptors) are unlikely to be reduced, and the continuous nature of vibroseis introduces new issues in relation to behavioural and masking effects. This technology is also not widely or commercially available. The identified alternative technologies may have limited or no additional environmental benefit and could attract a commercial and financial cost that is not justified.	No
Additional Controls Considered			
The Seismic Vessel will not return to acquire any un-surveyed portion of any sail line (i.e. infill acquisition or re-shooting) until at least 24-hours has passed.	P = No E = Effective	As infill acquisition has the potential to expose site attached benthic species (including fish species targeted by commercial fisheries), to a second dose of seismic energy within a relatively short period of time, TGS considered deferring any infill acquisition by 24 hours to reduce the cumulative seismic exposure risk to site-attached species. However, for the following reasons this potential control measure will not be implemented during the Otway Basin 3D MC MSS: • Infill acquisition is typically displaced by 500 – 1,000 m from the original line and rescheduled for a later date to promote survey efficiency; and • Injury effects for site attached marine fauna are spatially restricted (c. 500 m for crustaceans and not predicted at any distance for bivalves, sponges and corals) (see UAM results in Appendix B); • While TTS effects on fish are theoretically possible out to 4.8 km, such effects are contingent on sustained exposure over a 24-hour period which is operationally untenable on account of continuous movement of the Seismic Vessel even if both the original line and the infill were acquired within a 24-hour period. While re-shooting aims to replicate the original sail line, the reason for the re-shoot is usually that acquisition was shut down on the initial pass; hence cumulative exposure will not result from re-shooting.	No

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
A 100 m precautionary Shut-down Zone from the operating source will be applied to marine turtles. The acoustic source will be shut-down, or start-up will be delayed for 15 minutes if a marine turtle is observed within the 100 m Shut-down Zone. Operation of the acoustic source using soft-starts may only resume when the turtle has been observed to move outside the 100 m Shut-down Zone, or when 15 minutes have lapsed since the last turtle sighting.	P = Yes E = Effective	The Otway region does not support biologically significant populations or habitat for marine turtles, however, individuals (particularly leatherback turtles) may be present in the region. While the potential for turtles to occur in close proximity to the acoustic source during the Otway Basin 3D MC MSS is limited, in order to reduce the potential risks to marine turtles, a 100 m Shut-down Zone is considered to be a practicable measure to implement. A 100 m Shut-down Zone is considered to be conservative given that PTS and TTS effects are not predicted to be exceeded within the limited of the modelling resolution (i.e. 20 m). Based on SEL_{24hr} results, PTS may occur within 110 m and TTS may occur from accumulated exposures within 310 m of the acoustic source. The acoustic source will be shut-down, or start-up will be delayed for 15 minutes if a marine turtle is observed within the 100 m Shut-down Zone. Operation of the acoustic source using soft-starts may only resume when the turtle has been observed to move outside the 100 m Shut-down Zone, or when 15 minutes have lapsed since the last turtle sighting. Over the course of 15 minutes, the Seismic Vessel will travel approximately 2 km from the sighting location. Given that marine turtles are slow swimming relative to the Seismic Vessel, and due to their limited sensitivity to sound, the shut-down and start-up delay is considered protect against PTS and TTS effects. The 2 km distance that the vessel would travel from the sighting location is greater than the 1.37 km modelled Rmax for the 175 dB SPL significant behavioural disturbance threshold.	Yes
Policy Statement 2.1: Part B.1 – Marine Mammal Observers. The use of suitably trained, dedicated and experienced MFOs to undertake visual observations for whales and ensure that the appropriate mitigation measures outlined in this EP are implemented. MFOs onboard survey vessels to maintain vigilance for SBT while conducting watches for other marine fauna.	P = Yes E = Effective	The use of trained, dedicated and experienced MFOs s is a recommendation of Part B.1 of Policy Statement 2.1 when the likelihood of encountering whales is moderate to high. From the assessment undertaken within this EP (**Section 4.5.6**) it has been determined that the likelihood of encountering whales during the Otway Basin 3D MC MSS is high. Therefore, TGS will have two dedicated, trained and experienced MFOs onboard the Seismic Vessel for the duration of the Otway Basin 3D MC MSS and two dedicated, trained and experienced MFOs will be stationed on the Attending Support Vessel for the duration of the Otway Basin 3D MC MSS. The role of MFOs is to undertake all visual observations for marine fauna and to ensure that the appropriate mitigation measures, as outlined in this EP, occur in response to any marine fauna sightings. The use of two MFOs onboard the Seismic Vessel and two onboard the Attending Support Vessel provides some redundancy in the event one MFO is unavailable and facilitates the implementation of Extended Observation Zones for BW/PBW and SRW (see the specific controls that will be implemented for these species later in this table or **Appendix M**). At least one MFO on the Seismic Vessel and the Attending Support Vessel will perform marine mammal observations during daylight hours. All MFOs used during the Otway Basin 3D MC MSS must have proven 'at sea' experience in whale identification and behaviour, and distance estimation, and must be confident in the identification of those species that the EP predicts will be present in the OA. All MFOs will hold a JNCC Marine Mammal Observation certification (or equivalent). In addition, the lead MFO on the Seismic Vessel must have logged a minimum of 20 weeks' relevant sea-time engaged in marine seismic survey operations in Australian waters as an MFO. Following consultation with ASBTIA, TGS propose to have MFOs conducting visual observations for marine fauna to also record any observations of SBT aggregations and share sightings data with stakeholders. Sightings will be reported to ASBTIA within 24-hours of the observation being made. Environmental benefit gained outweighs the additional cost.	Yes
EPBC Act Policy Statement 2.1: Part B.2 – Night-time/Poor Visibility.	P = Yes E = Effective	Policy Statement 2.1 recommends that in areas where whales are expected to be encountered, the proponent should include measures to detect whale presence and apply measures to reduce the likelihood of encounters. Regarding this, a combination of PAM and adaptive management measures will be implemented to provide an effective spread of controls and, ultimately, level of protection to whales in the OA under night-time/poor visibility conditions. PAM requirements are outlined presently in this table. The adaptive management measures that relate to night time/poor visibility operations are: • Low Visibility or Night-time Operations may occur provided that there have not been three or more whale instigated shut-down situations during the preceding 24-hour period.	Yes

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
		• Low Visibility or Night-time Operations may occur provided that no BW/PBW shut downs have been instigated during the preceding 24 hours within 32 km of the planned acquisition (i.e. the survey lines that will occur during the hours of darkness or the period of low visibility); however Low Visibility and Night Time Operations inside the BW BIAs/buffer are contingent on aerial surveys occurring within 7 days prior to acquisition occurring here. • Low Visibility or Night-time Operations may occur provided the no SRW shut downs have been instigated during the preceding 24 hours within 42 km of the planned acquisition (i.e. the survey lines that will occur during the hours of darkness or the period of low visibility); however Low Visibility and Night Time Operations inside the SRW Ag BIA/buffer are contingent on aerial surveys occurring within 7 days prior to acquisition occurring here. • Soft starts may only commence at night or during periods of low visibility providing they occur outside of the BW BIAs/buffer and the SRW Ag BIA/buffer providing acquisition has occurred within the preceding 24 hours and no whale initiated shut downs have been made during this period. Note that a combination of control and adaptive management measures are proposed to reduce reliance on PAM, which is not considered to be a particularly reliable method for detecting low-frequency cetaceans. Environmental benefit gained outweighs the additional cost.	
A PAM System will run 24-hours per day on the Seismic Vessel during the Otway Basin 3D MC MSS, with dedicated, trained, and experienced PAM Operators conducting acoustic monitoring for the presence of cetaceans while the acoustic source is active and during the 30 minutes before the commencement of any Soft Start Procedures. At least two dedicated, trained, and experienced PAM Operators will be on the Seismic Vessel for the duration of the Otway Basin 3D MC MSS, with at least one PAM Operator maintaining acoustic watch at all times while the acoustic source is active and during the 30 minutes prior to the commencement of any Soft Start Procedure.	P = Yes E = Effective	Visual methods of scanning for whales are restricted to daylight hours and relatively calm weather conditions. Animal behaviour such as diving further reduces detection probability (Verfuss *et al*., 2018). PAM detects whale vocalisations in real-time and is useful during night-time, low visibility operations and for submerged animals. The use of PAM is a suggestion under Part B.5 (Additional Measures) of Policy Statement 2.1 when the likelihood of encountering whales is moderate to high. TGS will run and monitor a PAM system around the clock while the acoustic source is active and during the 30 minutes before the commencement of any Soft Start Procedures; hence, detections of cetacean vocalisations will occur both at night and during daylight hours (to augment visual detections). The PAM system will be programmed to cover the frequency range 10 Hz to 200 kHz to theoretically detect a) low frequency vocalisations of baleen whales, and b) the high frequency echolocation clicks of sperm whales. Two trained, dedicated and experienced PAM Operators will be on the Seismic Vessel for the duration of the Otway Basin 3D MC MSS, with at least one PAM Operator maintaining 'acoustic watch' at all times. The lead PAM Operator must have logged a minimum of 20 weeks' relevant sea-time engaged in seismic survey operations in Australian waters as a PAM Operator (following the recommendation of the Marine Mammal Observer Association (MMOA, 2019). All PAM Operators will need to be able to demonstrate competency in the acoustic identification of the species that are likely to be present during the Otway Basin 3D MC MSS, and in interpreting acoustic software and estimating distance to any detected whale calls. PAM experience will be a pre-requisite for the recruitment of personnel for these positions. A full replacement PAM system will be kept onboard the Seismic Vessel and will be used as a back-up in the event that the PAM system malfunctions and is unable to be repaired. In the event that the PAM system malfunctions or becomes damaged, seismic operations may continue for 20 minutes without PAM while the PAM Operator diagnoses the issue. If it is found that the PAM system needs to be repaired or replaced, seismic operations may continue for an additional two hours without operational PAM as long as: a) it is daylight hours and the sea state is less than or equal to Beaufort 4, b) no whales were detected solely by PAM in the relevant mitigation zones in the previous two hours; c) two MFOs maintain watch at all times during seismic operations when PAM is not operational, d) seismic operations with an active source, but without an active PAM system, do not exceed a cumulative total of four hours in any 24-hour period. Frequency sensitivity will be designed into the hardware to remove vessel noise at very low frequencies masking whale vocalisations which may limit the performance of PAM.	Yes

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
		PAMGuard software will be incorporated into the PAM system to assist with locating and classifying the vocalisations of marine mammals. This sophisticated software allows the trained PAM Operators to make robust decisions during real-time mitigation operations, such as requesting shutdowns based on whales entering the Precaution Zones. The full PAM specs that will be implemented for the Otway Basin 3D MC MSS are provided in **Appendix L**. Environmental benefit gained outweighs the additional cost.	
Use of PAM on support vessel/s.	P = No E = Effective	PAM provides a useful detection method in addition to visual observations by MFOs and will be implemented onboard the Seismic Vessel. However, due to the limited capacity for additional personnel onboard the support vessel/s, the limitations of PAM systems to detect baleen whales, and the significant costs associated with engaging suitable PAM Operators and equipment, the cost of this option is considered to outweigh the limited potential for any further risk reduction that will not already be provided by the PAM system onboard the Seismic Vessel.	No
Policy Statement 2.1: B.3 – Use of spotter aircraft and vessels to detect presence of cetaceans. Observers conducting periodic aerial surveys will also record any sightings of SBT aggregations.	P = Yes E = Effective	Part B of Policy Statement 2.1 suggest spotter vessels and aircraft may be employed to determine the presence and likelihood of encountering whales where the likelihood of encountering whales is high. Given the proximity of the Otway Basin 3D MC MSS to the BW foraging BIAs and the SRW Ag BIA, it Is predicted that whale densities will be higher in the inshore sections of the OA where they approach or overlap these BIAs. The following apply to aerial surveys for the Otway Basin 3D MC MSS: • All reasonable efforts will be made to ensure that aerial surveys will be conducted to assist with the detection of BW/PBW in the BW BIAs/buffer during the 'foraging shoulder season'. Within the seven days prior to commencement of any acquisition in the BW BIAs/buffer aerial surveys will be flown, if possible, to identify any BW/PBWs that may be present. Any such detections will result in acquisition within the BW BIAs/buffers being redirected away from areas in which such detections have been made. The intent of this control is to allow TGS to respond adaptively to detections of BW/PBWs in the BW BIAs/buffer by relocating to parts of the BW BIAs/buffer where potential impacts on BW/PBWs are less likely. If this requirement for aerial surveys cannot be achieved, no low visibility or night time operations may occur inside the BW BIAs/buffer until such time as the aerial survey requirement is met. Aerial survey efforts will concentrate on the area of the BW BIAs/buffer nearest to the proposed start up location and/or those waters that will be subject to acquisition in the first 24 hours of planned seismic operations. Throughout the period in which acquisition is underway, aerial surveys will be flown periodically as weather permits to support the detection of BW/PBW and to redirect seismic survey efforts in order to avoid BW/PBW that are present. Aerial surveys must be undertaken by two experienced observers from a suitable aircraft. At least one of these observers must demonstrate previous experience in the detection and identification of BW/PBW from the air. • All reasonable efforts will be made to ensure aerial surveys will be conducted to assist with the detection of SRWs in the SRW Ag BIA/buffer during April and October. Within the seven days prior to commencement of any acquisition in the SRW Ag BIA/buffer, aerial surveys will be flown, if possible, to identify any SRW that may be present. Any such detections will result in acquisition within the SRW Ag BIA/buffer being redirected away from areas in which such detections have been made. The intent of this control is to allow TGS to respond adaptively to detections of SRWs in the SRW Ag BIA/buffer by relocating to parts of the OA where potential impacts on SRWs are less likely. If this requirement for aerial surveys cannot be achieved, no low visibility or night time operations may occur inside the BW BIAs/buffer until such time as the aerial survey requirement is met. Aerial survey efforts will concentrate on the area of the SRW Ag BIA/buffer nearest to those waters that will be subject to acquisition in the first 24 hours of planned seismic operations. Aerial surveys should also monitor any nearby waters of the known core range BIA that acquisition will soon occur in. Throughout the period in which acquisition in the SRW Ag BIA/buffer is underway, aerial surveys will be flown periodically as weather permits to support the detection of SRWs and to redirect seismic survey efforts in order to avoid areas where SRWs are present. Aerial surveys must be undertaken by two experienced observers from a suitable aircraft. At least one of these observers must demonstrate previous experience in the detection and identification of SRW from the air.	Yes

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
		• Aerial surveys will also be used to support whale detection efforts prior to 2D tie line acquisition. 2D tie line acquisition inside any BIA/buffer can occur at any time providing an aerial survey has been conducted within 4 days of such operations commencing and no baleen whales have been detected. This aerial survey must focus on the area of planned acquisition that overlaps the BIA/buffer and must extend to at least 42 km on either side of the planned 2D sail line. Following consultation with ASBTIA, TGS proposed to have MFOs conducting visual observations for marine fauna to also record any observations of SBT aggregations and share sightings data with relevant persons. MFOs onboard the survey vessels and conducting periodic aerial surveys for the Otway Basin 3D MC MSS will also conduct observations for aggregations of SBT, with any sightings reported to ASBTIA within 24-hours of the observation being made. Environmental benefit gained outweighs the additional cost.	
Policy Statement 2.1: B.4 – Increased Precaution Zones. The Shut-down Zone will be extended to 7 km from the acoustic source for BW/PBW and SRW and 2 km from the acoustic source for all 'other whales'. In addition, if a SRW mother-calf pair is observed from the Seismic Vessel or the Attending Support Vessel at any distance during the Otway Basin 3D MC MSS, the acoustic source will be immediately shut down. When species identification is uncertain, a precautionary approach will be taken, and the most conservative option in accordance with the additional management procedures for BW/PBW or SRWs will be followed until identification is otherwise confirmed.	P = Yes E = Effective	Policy Statement 2.1 defines the standard Shut-down Zone as being 500 m from the acoustic source with a Low-power Zone out to 2 km. In keeping with their precautionary approach, TGS have committed to extending the Shut-down Zone out to 7 km from the acoustic source for BW/PBW and SRW and 2 km from the acoustic source for all 'other whales'. Detection of a SRW mother-calf pair from the Seismic Vessel or the Attending Support Vessel at any distance will trigger an immediate shut down. When species identification is uncertain, a precautionary approach will be taken, and the additional management procedures for BW/PBW or SRW will be followed until identification is otherwise confirmed. Environmental benefit gained outweighs the additional cost.	Yes
Policy Statement 2.1: B.6 Adaptive Management Measures: all whales. If there have been three or more whale instigated shut-down situations during the preceding 24-hour period, then low visibility or night-time operations must not occur.	P = Yes E = Effective	If there have been three or more whale instigated shut-down situations during the preceding 24-hour period, then low visibility or night-time operations must not occur. In addition to this adaptive management controls specific to BW/PBW and SRWs are presented in this table below. Decisions on the implementation of these controls will be made daily, i.e. at dusk each day, the MFO on-duty will advise whether these thresholds have been triggered and will confirm if night-time operations can occur. The same applies for low visibility operations where decisions on whether to continue operating will be made each time low visibility conditions arise. Environmental benefit gained outweighs the additional cost.	Yes
Policy Statement 2.1: B.6 Adaptive Management Measures: blue whales/pygmy blue whales Adaptive management controls will be implemented for BW/PBW if higher than anticipated numbers of BW/PBWs are observed (three or more BW/PBW instigated shut downs are made during the preceding 48 hour period).	P = Yes E = Effective	In accordance with Policy Statement 2.1, adaptive management procedures will be adopted for BW/PBW as follows: • If higher than anticipated numbers of BW/PBW are observed (three or more BW/PBW instigated shut-downs are made during the preceding 48 hour period) at any time or location during the Otway Basin 3D MC MSS, the following adaptive management controls will apply: a. Acquisition in the BW BIAs/buffer must cease; b. Low Visibility or Night-time Operations must cease; and c. Normal operations may only resume after 24 hours of no BW/PBW instigated shut-downs. When species identification is uncertain, a precautionary approach will be taken, and the most conservative option in accordance with the additional management procedures for BW/PBW or SRWs will be followed until identification is otherwise confirmed. Environmental benefit gained outweighs the additional costs.	Yes
Policy Statement 2.1: B.6 Adaptive Management Measures: southern right whales Adaptive management controls will be implemented for SRW in the following circumstances: • If higher than anticipated numbers of SRWs are observed (three or more SRW instigated shut-downs are made during the preceding 48 hour period); or • If a SRW mother-calf pair is observed from the Seismic Vessel or the Attending Support Vessel.	P = Yes E = Effective	In accordance with Policy Statement 2.1, adaptive management procedures will be adopted for SRW as follows: • If higher than anticipated numbers of SRW are observed (three or more SRW instigated shut-downs are made during the preceding 48 hour period) at any time or location during the Otway Basin 3D MC MSS, the following adaptive management controls will apply: a. Acquisition in the SRW Ag BIA/buffer must cease b. Low Visibility or Night-time Operations must cease;	Yes

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
		c. The acoustic source will be shut-down and the Seismic Vessel will relocate to another area at least 42 km away from the last SRW sighting, and outside of the SRW Ag BIA/buffer, before commencing Pre Start-up Visual Observations and Soft Start Procedures. If relocation of the seismic vessel is not possible, then acquisition will cease and will not recommence until 24 hours have elapsed and no SRW has been detected in the 7 km Extended Shut-down Zone; and d. Normal operations may only resume after 24 hours of no SRW instigated shut-downs. • If a SRW mother-calf pair is observed from the Seismic Vessel or the Attending Support Vessel at any distance during the Otway Basin 3D MC MSS, the acoustic source will be immediately shut-down and the Seismic Vessel will relocate to another area at least 42 km away, and outside of the SRW Ag BIA/buffer, before commencing Pre Start-up Visual Observations and Soft Start Procedures. If relocation of the seismic vessel is not possible, then acquisition will cease and will not recommence until 24 hours have elapsed and no SRW has been detected in the 7 km Extended Shut-down Zone. When species identification is uncertain, a precautionary approach will be taken, and the most conservative option in accordance with the additional management procedures for BW/PBW or SRWs will be followed until identification is otherwise confirmed. Environmental benefit gained outweighs the additional cost.	
Policy Statement 2.1: B.6 Adaptive Management Measures: other whales Adaptive management controls will be implemented for other whales in the following circumstances: • If higher than anticipated numbers of other whales are observed (three or more instigated shut-downs are made during the preceding 24-hour period); or • If an 'other whale' mother-calf pair is observed within 12 km of the active acoustic source.	P = Yes E = Effective	In accordance with Policy Statement 2.1, adaptive management procedures will be adopted for 'other whales' as described below. • If three or more 'other whale' instigated shut-downs occur within a 24-hour period, the Seismic Vessel will relocate at least 12 km in the direction away from the sightings before commencing Pre Start-up Visual Observations and Soft Start Procedures; and • If an 'other whale' mother-calf pair is observed within 12 km of the active acoustic source during the Otway Basin 3D MC MSS, the acoustic source will be immediately shut-down and the Seismic Vessel will relocate to another area at least 12 km away from the last recorded position of the mother-calf pair before commencing Pre Start-up Visual Observations and Soft Start Procedures. When species identification is uncertain, a precautionary approach will be taken, and the most conservative option in accordance with the additional management procedures for BW/PBW or SRWs will be followed until identification is otherwise confirmed. Environmental benefit gained outweighs the additional cost.	Yes
Additional Management Measures – Blue Whales/Pygmy Blue Whales to allow Biologically Important Behaviours to Continue: • No operation of the acoustic source within 16 km of any BW/PBW BIA during the period January to June (inclusive) which represents the peak foraging season during which BW/PBW are expected to consistently be present at foraging areas in and around the OA at elevated densities. The only exception allowed relates to the acquisition of the 2D tie line. • Implementation of an Extended 7 km Shut-down Zone[AC]; • Additional MFO observation effort (including aerial surveys); and • Implementation of adaptive management measures.	P = Yes E= Effective	In addition to the above-mentioned Standard and Adaptive Management Control Measures, the following control measures are proposed to afford a high level of protection to endangered BW/PBW during the Otway Basin 3D MC MSS. In particular, the BW Conservation Management Plan includes the following action: "*Anthropogenic noise in biologically important areas will be managed such that any blue whale continues to utilise the area without injury and is not displaced from a foraging area*". In addition, one of the CMPs interim objectives is that "*anthropogenic threats are demonstrably minimised*" and in particular "*Robust and adaptive management regimes leading to a reduction in anthropogenic threats to Australian blue whale are in place*". The proposed additional management procedures for BW/PBW have been developed to ensure consistency with these requirements. Cumulative TTS effects from acquisition on the continental slope are predicted to occur to 15.4 km inshore of the active acoustic source and out to 32 km offshore of the acoustic source; and the maximum predicted onset distance for behavioural impacts for PBW is 7 km (see **Section 7.2.2.2.7** and **Section 7.2.2.3.6**). To mitigate the effects of the Otway Basin 3D MC MSS on biologically important behaviours, the following additional management procedures are proposed to be implemented for BW/PBW during the Otway Basin 3D MC MSS (following **Appendix M**): • BMP 1: A 16 km buffer will be established around all BW BIAs where they overlap or approach the OA.	Yes

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
		• BMP 2: The Seismic Vessel will not activate the acoustic source(s) within any BW BIAs/buffer from January to June (inclusive) which represents the peak foraging season during which BW/PBW are expected to consistently be present at foraging areas in and around the OA at elevated densities. The only exception allowed relates to the acquisition of the 2D tie line in accordance with the criteria outlined in **AMP 2** in **Appendix M**. • BMP 3: A 7 km Extended Shut-down Zone will be implemented for BW/PBW throughout the OA (including the BW BIAs/buffer). On this basis a Low Power Zone is deemed unnecessary. • BMP 4: An 'Extended Observation Zone' will be adopted such that vessel based MFOs observe for BW/PBWs as far as practicable, and to a minimum of 7 km during daylight hours. During periods when visibility is < 7 km, the Extended Observation Zone will be monitored by the combined efforts of the MFOs on both the Seismic Vessel and at least one Support Vessel travelling approximately 5 – 7 km ahead of the Seismic Vessel. This Support Vessel will focus monitoring efforts on the 90° quadrant that lies directly ahead of the Seismic Vessel, and in reference to these specific duties, is herein referred to as the EOZ Support Vessel. When visibility is > 7 km, this Extended Observation Zone may be monitored solely by MFOs on the seismic vessel. At these times the EOZ Support Vessel will be available to assist with vessel operations and port calls; however, whenever possible the intention is that the EOZ Support Vessel shall maintain its position 5 – 7 km ahead of the seismic vessel to assist with BW/PBW detections. The only permissible exceptions to the specified EOZ Support Vessel duties will be issues of safety that require relocation of the EOZ Support Vessel or in the event of incidents involving significant risk to in-sea equipment when the EOZ Support Vessel will be permitted to temporarily assist providing the following criteria are met: a. The MFO onboard the EOZ Support Vessel continues observations for BW/PBWs; b. There have been no BW/PBW instigated shut-downs in the preceding 6 hours; and c. No more than 4 hours elapse before the EOZ Support Vessel resumes its position ahead of the Seismic Vessel. • BMP 5: Low Visibility or Night-time Operations may occur provided that no BW/PBW shut-downs have been instigated during the preceding 24 hours within 32 km of the planned acquisition (i.e. the survey lines that will occur during the hours of darkness or the period of low visibility). • BMP 6: During the 'foraging shoulder season' months of September to December and July the seismic vessel is permitted to operate in the BW BIAs/buffer in accordance with the following protocols: a. All reasonable efforts[36] will be made to ensure that aerial surveys will be conducted to assist with the detection of BW/PBW in the BW BIAs/buffer during the 'foraging shoulder season'. Within the seven days prior to commencement of any acquisition in the BW BIAs/buffer aerial surveys will be flown, if possible, to identify any BW/PBWs that may be present. Any such detections will result in acquisition within the BW BIAs/buffers being redirected away from areas in which such detections have been made. The intent of this control is to allow TGS to respond adaptively to detections of BW/PBWs in the BW BIAs/buffer by relocating to parts of the BW BIAs/buffer where potential impacts on BW/PBWs are less likely. b. If the requirement for aerial surveys as outlined in (a) above cannot be achieved, no low visibility or night time operations may occur inside the BW BIAs/buffer until such time as the aerial survey requirement is met. c. Aerial survey efforts will concentrate on the area of the BW BIAs/buffer nearest to the proposed start up location and/or those waters that will be subject to acquisition in the first 24 hours of planned seismic operations. Throughout the period in which acquisition is underway, aerial surveys will be flown periodically as weather permits to support the detection of BW/PBW and to redirect seismic survey efforts in order to avoid BW/PBW that are present.	

[36] Noting that in some circumstances aerial surveys may not be possible due to weather or aircraft availability constraints.

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
		d. Aerial surveys must be undertaken by two experienced observers from a suitable aircraft. At least one of these observers must demonstrate previous experience in the detection and identification of BW/PBW from the air. e. Start-up (via soft start) can only commence in the BW BIAs/buffer during the 'foraging shoulder season' if the following criteria are met: v. A minimum of two hours of daylight remain before nightfall; vi. Good sightings conditions prevail that allow visual observations of the Extended Observation Zone; vii. MFOs on board the Seismic Vessel and the EOZ Support Vessel have completed at least 30 minutes of pre-start observation procedures and confirmed no BW/PBW have been sighted; and viii. The start-up location does not occur within 32 km of an area where a BW/PBW detection has been made in the last four days. • BMP 7: If a BW/PBW is detected in the 7 km Extended Shut-down Zone during the survey the acoustic source will be immediately shut-down and the seismic vessel will relocate to another area at least 32 km away from the last PBW sighting before commencing Pre Start-up Visual Observations and Soft Start Procedures. If relocation of the seismic vessel is not possible[37], then acquisition will cease and will not recommence until 24-hours have elapsed and no BW/PBW has been detected in the 7 km Extended Shut-down Zone. • BMP 8: A Start-up Delay will occur if a BW/PBW enters or is detected in the 7 km Extended Shut-down Zone during the soft start, and soft start procedures may only resume once the BW/PBW is observed to move outside this Shut-down Zone or when 30 minutes have lapsed since the last BW/PBW sighting. • BMP 9: If higher than anticipated numbers of BW/PBW are observed (three or more BW/PBW instigated shut downs are made during the preceding 48 hour period[38]) at any time or location during the survey, the following adaptive management controls will apply: a. Acquisition in the BW BIAs/buffer must cease; b. Low Visibility or Night-time Operations must cease; and c. Normal operations may only resume after 24 hours of no BW/PBW instigated shut downs. In light of the conservative approach taken by the modelling, the proposed controls (as outlined below) demonstrate consistency with the objective of the BW Conservation Management Plan (that "anthropogenic threats are demonstrably minimised") and the purpose of the Australian Whale Sanctuary (that cetaceans are not killed, injured, or interfered). On this basis, acoustic injury to BW/PBW can be avoided managed to an acceptable level throughout the OA; hence, anthropogenic threats (as they relate to physiological impacts from underwater noise) are minimised through robust and adaptive management measures. Environmental benefit gained outweighs the additional cost.	
Additional Management Measures – Southern Right Whales to allow Biologically Important Behaviours to Continue: • No operation of the acoustic source within 42 km of the SRW Ag BIA during the core aggregation months of May to September; • Implementation of an Extended 7 km Shut-down Zone[AC]; • Additional MFO observation effort (including aerial surveys); and • Implementation of adaptive management measures.	P = Yes E= Effective	In addition to the above-mentioned Standard and Adaptive Management Control Measures, the following control measures are proposed to afford a high level of protection to endangered SRWs during the Otway Basin 3D MC MSS. The operative SRW Conservation Management Plan (CoA, 2012) states that "*Noise interference is of particular concern within or close to southern right whale aggregation areas where young calves are present and whales are resident for long periods of time*"; hence the measures described below are targeted to address these specific noise impacts. While there is another designated 'known core range' BIA in the area, the OA only marginally overlaps with this, and the expectation is that animals traverse this area on their way to and from the more coastal aggregation	Yes

[37] For instance, towards the end of the survey when few survey lines remain to be acquired.
[38] Note that any unidentified whale/s will contribute to this count.

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
		areas and connecting habitat. Strong adaptive management measures have been developed to address potential noise effects in the wider area. The 42 km onset distance for behavioural impacts to mother-calf pairs has been used to define a buffer zone around the SRW Aggregation BIA (referred to as the SRW Ag BIA herein). No acquisition will occur within the SRW Ag BIA or the 42 km buffer during the core aggregation months of May to September (SWIFFT, 2023). The only exception allowed is the acquisition of the 2D tie line which will be subject to additional operational restrictions (see **AMP 2** in **Appendix M**) and will only take approximately 12 hours to acquire. This spatio-temporal measure has been designed to eliminate any physiological or behavioural effects on SRWs in the SRW Ag BIA during the months over which SRWs are expected to be present. On this basis, compliance with Interim Recovery Objective 5 of the operative Southern Right Whale Conservation Management Plan that anthropogenic threats are demonstrably minimised, is achieved. This control also aligns with the recommendation in Policy Statement 2.1 that seismic surveys should be undertaken outside of biologically important areas at biologically important times. While the Draft National Recovery Plan for the Southern Right Whale (CoA, 2022) is not yet operative, once finalised it will supersede the current operative plan. The conservation actions included in the draft plan that are of relevance to seismic survey noise are listed in **Table 79** along with how they are addressed by the proposed controls. TGS is aware that the designated BIAs are also being reviewed as part of the process underpinning the review of the recovery plan. There is a strong possibility that the BIA boundaries for SRWs will change prior to the commencement of the proposed Otway Basin 3D MC MSS. TGS can confirm that the 42 km buffer as described above will be applied to the updated aggregation/reproductive BIA should it be published before the Otway Basin 3D MC MSS commences. To mitigate the effects of the Otway Basin 3D MC MSS on biologically important behaviours, the following additional management procedures are proposed to be implemented for SRWs during the Otway Basin 3D MC MSS (following **Appendix M):** • <u>SRMP 1:</u> A 42 km buffer will be established around the SRW Ag BIA where it approaches the OA. • <u>SRMP 2:</u> The Seismic Vessel will not activate the acoustic source(s) within the SRW Ag BIA/buffer from May to September (inclusive) which represents the core aggregation months during which SRWs are expected to be present here. The only exception allowed relates to the acquisition of the 2D tie line in accordance with the criteria outlined in **AMP 2** in **Appendix M**. • <u>SRMP 3</u>: A 7 km Extended Shut-down Zone will be implemented for SRWs throughout the OA (including the SRW Ag BIA/buffer). On this basis a Low Power Zone is deemed unnecessary. • <u>SRMP 4</u>: An 'Extended Observation Zone' will be adopted such that vessel based MFOs observe for SRWs as far as practicable, and to a minimum of 7 km during daylight hours. During periods when visibility is < 7 km, the Extended Observation Zone will be monitored by the combined efforts of the MFOs on both the Seismic Vessel and at least one Support Vessel travelling approximately 5 – 7 km ahead of the Seismic Vessel. This Support Vessel will focus monitoring efforts on the 90° quadrant that lies directly ahead of the Seismic Vessel, and in reference to these specific duties, is herein referred to as the EOZ Support Vessel. When visibility is > 7 km, this Extended Observation Zone may be monitored solely by MFOs on the seismic vessel. At these times the EOZ Support Vessel will be available to assist with vessel operations and port calls; however, whenever possible the intention is that the EOZ Support Vessel shall maintain its position 5 – 7 km ahead of the seismic vessel to assist with SRW detections. The only permissible exceptions to the specified EOZ Support Vessel duties will be issues of safety that require relocation of the EOZ Support Vessel or in the event of incidents involving significant risk to in-sea equipment when the EOZ Support Vessel will be permitted to temporarily assist providing the following criteria are met: a. The MFO onboard the EOZ Support Vessel continues observations for SRWs; b. There have been no SRW instigated shut-downs in the preceding 6 hours; and c. No more than 4 hours elapse before the EOZ Support Vessel resumes its position ahead of the Seismic Vessel.	

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
		• <u>SRMP 5:</u> Low Visibility or Night-time Operations may occur provided that no SRW shut-downs have been instigated during the preceding 24 hours within 42 km of the planned acquisition (i.e. the survey lines that will occur during the hours of darkness or the period of low visibility). • <u>SRMP 6:</u> During April and October (shoulder aggregation months) the Seismic Vessel is permitted to operate in the SRW Ag BIA/buffer in accordance with the following protocols: a. All reasonable efforts will be made to ensure aerial surveys will be conducted to assist with the detection of SRWs in the SRW Ag BIA/buffer during April and October. Within the seven days prior to commencement of any acquisition in the SRW Ag BIA/buffer, aerial surveys will be flown, if possible, to identify any SRW that may be present. Any such detections will result in acquisition within the SRW Ag BIA/buffer being redirected away from areas in which such detections have been made. The intent of this control is to allow TGS to respond adaptively to detections of SRWs in the SRW Ag BIA/buffer by relocating to parts of the OA where potential impacts on SRWs are less likely. b. If the requirement for aerial surveys as outlined in (a) above cannot be achieved, no low visibility or night time operations may occur inside the BW BIAs/buffer until such time as the aerial survey requirement is met. c. Aerial survey efforts will concentrate on the area of the SRW Ag BIA/buffer nearest to those waters that will be subject to acquisition in the first 24 hours of planned seismic operations. Aerial surveys should also monitor any nearby waters of the known core range BIA that acquisition will soon occur in. Throughout the period in which acquisition in the SRW Ag BIA/buffer is underway, aerial surveys will be flown periodically as weather permits to support the detection of SRWs and to redirect seismic survey efforts in order to avoid areas where SRWs are present. d. Aerial surveys must be undertaken by two experienced observers from a suitable aircraft. At least one of these observers must demonstrate previous experience in the detection and identification of SRW from the air. e. Start-up (via soft start) can only commence in the SRW Ag BIA/buffer during April and October if the following criteria are met: vi. A minimum of two hours of daylight remain before nightfall; vii. Good sightings conditions prevail that allow visual observations of the Extended Observation Zone; viii. A Support Vessel is available to undertake the requisite marine mammal monitoring; ix. MFOs on board the Seismic Vessel and the EOZ Support Vessel have completed at least 30 minutes of pre-start observation procedures and confirmed no SRWs have been sighted; and x. The start-up location does not occur within 42 km of an area where a SRW detection has been made in the last four days. • <u>SRMP 7:</u> If a SRW is detected in the 7 km Extended Shut-down Zone during the survey the acoustic source will be immediately shut-down and the seismic vessel will relocate to another area at least 11 km away from the last SRW (unaccompanied) sighting before commencing Pre Start-up Visual Observations and Soft Start Procedures. Note that this distance increases if a calf is present in accordance with **SRMP 10**. If relocation of the seismic vessel is not possible, then acquisition will cease and will not recommence until 24 hours have elapsed and no SRW has been detected in the 7 km Extended Shut-down Zone. • <u>SRMP 8</u>: A Start-up Delay will occur if a SRW enters or is detected in the 7 km Extended Shut-down Zone during soft start, and soft start procedures may only resume once the SRW is observed to move outside this Shut-down Zone or 30 minutes have lapsed since the last SRW sighting.	

<table>
<tr><th>Control Measure</th><th>Practicability/ Effectiveness</th><th>Justification</th><th>Will it be adopted?</th></tr>
<tr><td></td><td></td><td>SRMP 9: If higher than anticipated numbers of SRW are observed (three or more SRW instigated shut downs are made during the preceding 48 hour period[39]) at any time or location during the survey, the following adaptive management controls will apply:
a. Acquisition in the SRW Ag BIA/buffer must cease
b. Low Visibility or Night-time Operations must cease;
c. The acoustic source will be shut down and the Seismic Vessel will relocate to another area at least 42 km away from the last SRW sighting, and outside of the SRW Ag BIA/buffer, before commencing Pre Start-up Visual Observations and Soft Start Procedures. If relocation of the seismic vessel is not possible, then acquisition will cease and will not recommence until 24 hours have elapsed and no SRW has been detected in the 7 km Extended Shut-down Zone; and
d. Normal operations may only resume after 24 hours of no SRW instigated shut downs.
SRMP 10: If a SRW mother and calf pair is observed from the Seismic Vessel or the Attending Support Vessel at any distance during the Otway Basin 3D MC MSS, the acoustic source will be immediately shut-down and the Seismic Vessel will relocate to another area at least 42 km away, and outside of the SRW Ag BIA/buffer, before commencing Pre Start-up Visual Observations and Soft Start Procedures. If relocation of the seismic vessel is not possible, then acquisition will cease and will not recommence until 24 hours have elapsed and no SRW has been detected in the 7 km Extended Shut-down Zone.
In light of the conservative approach taken by the modelling, the proposed controls (as outlined below) demonstrate consistency with the objectives of both the operative SRW Conservation Management Plan (that anthropogenic threats are demonstrably minimised) and the purpose of the Australian Whale Sanctuary (that cetaceans are not killed, injured, or interfered).
In addition to the measures outlined above, TGS has contacted the Department of Energy, Environment, and Climate Action (DEECA) to enquire about the possibility of establishing a data sharing agreement whereby TGS receive notifications of SRW sightings (date and location) in a timely fashion throughout the SRW breeding season (via WhaleFace or other platforms that feed into the DEECA Southern Right Whale Sightings Database). DEECA has agreed to provide periodic in-season updates of sightings to TGS throughout the duration of the Otway Basin 3D MSS. DEECA has also agreed to provide sightings summaries from the monthly aerial surveys that they undertake throughout each breeding season. This data sharing arrangement will enable operational activity to be redirected away from areas in which whales are known to be present; hence will assist with reducing any potential impacts on this endangered species.
Environmental benefit gained outweighs the additional cost.</td><td></td></tr>
<tr><td>Additional Management Measures – other whales:
A 2 km Extended Shutdown Zone[AC] for ‘other whales’ will be implemented throughout the entire OA at all times. On this basis a low power zone is deemed unnecessary.
Soft starts at night and during periods of low visibility will also be limited[AC] as will acquisition of the 2D tie line within any BIA/buffer[AC].</td><td>P = Yes
E= Effective</td><td>In addition to the above-mentioned Standard and Adaptive Management Control Measures, the following control measures are proposed to afford a high level of protection to all other whales during the Otway Basin 3D MC MSS in accordance with the intention of the Australian Whale Sanctuary:
Soft start procedures throughout the OA can only proceed under the following circumstances:
a. If no acquisition has occurred in the preceding 24 hours, soft starts may only commence in daylight hours and when conditions allow visual inspection of the 5+ km Observation Zone[AC];
b. If acquisition has occurred within the preceding 24 hours and no whale initiated shut-downs have been made during this period, then soft starts may commence at night or during periods of low visibility providing they occur outside of the BW BIAs/buffer and the SRW Ag BIA/buffer.
2D tie line acquisition inside any BIA/buffer will only be permitted to occur in daylight hours, and two MFOs must be on duty on the Seismic Vessel and two MFOs must be on-duty on the Attending Support Vessel. 2D tie line acquisition inside any BIA/buffer can occur at any time providing the following criteria are met:</td><td>Yes</td></tr>
</table>

[39] Note that any unidentified whale/s will contribute to this count.

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
		a. An aerial survey has been conducted within 4 days of such operations commencing and no baleen whales have been detected. This aerial survey must focus on the area of planned acquisition that overlaps the BIA/buffer and must extend to at least 42 km on either side of the planned 2D sail line; b. 2D tie line acquisition inside any BIA/buffer must not occur for more than 12 hours total within any 24 hour period; c. The Extended Observation Zone as described in BMP 4 is implemented; and d. The acoustic source must not be active for more than a combined total of 20 hours (maximum) in the BIAs/buffers. Environmental benefit gained outweighs the additional cost.	
No acquisition overlapping the West Tasmanian Canyons KEF.	P = No E= Limited Effectiveness	This would result in the removal of 3,769 km² of area from the proposed OA, equating to approximately 8.9% of the OA and TGS would not be able to obtain sufficient data for all hydrocarbon prospects being targeted. The West Tasmania Canyons KEF is considered to be of importance due to the topography and bathymetry within the KEF which support a high biodiversity of benthic invertebrates and facilitate high productivity. Due to the water depths present within the West Tasmania Canyons KEF, there will be no impacts on the benthic invertebrate communities present within the KEF. The adopted criteria of 226 dB re 1 µPa PK, which is the threshold for no effects for sponges and coral, was not detected at any distance from the 3,480 in³ acoustic source (Welch *et al.*, 2023). Control is not practicable to implement and cost outweighs environmental benefit gained.	No
Consider adopting varying Seismic Vessel relocation distances following whale instigated shut-downs to account for propagation variation inshore/offshore/end-fire.	P = No E = Unknown Effectiveness	The results of the modelling confirm that underwater propagation of seismic survey noise varies depending on the direction it travels in relation to both the acoustic source and the local bathymetry (**Appendix B**). Because of this, the contour at which the threshold level for TTS in marine mammals is not symmetrical around the acoustic source. Using BW/PBW as an example, the animat modelling indicates that in the offshore direction the TTS threshold is exceeded out to 32 km, but in the onshore direction the TTS threshold is only exceeded out to c. 16 km, the distance to this threshold would change again in the end-fire direction. TGS notes that some recent seismic surveys in Australian waters have used this directional variation in propagation to set their requirements for seismic vessel relocation following marine mammal instigated shut-downs. While this approach has the potential to reduce the relocation distance in certain directions from the acoustic source, it is also a complex and imprecise control regime to implement. TGS considers that this complexity increases the likelihood of non-compliances and for this reason this approach will not be taken during the Otway Basin 3D MSS. Instead, and in accordance with the precautionary principle, when relocation distances have been defined, they have been informed by the maximum relevant onset distance in each instance.	No
Consider a shut-down requirement for BW/PBW mother-calf pairs at any distance in line with the requirement for SRWs.	P = No E = Very Effective	For cetaceans (as with most animals) mother-calf pairs are generally regarded as the cohort that is most vulnerable to disturbance. For this reason, they are often offered a higher level of protection than other cohorts. Blue whale presence in the OA is not typified by reproductive behaviours (which occur in Indonesian waters, see **Section 4.5.6.1.1**) and the level of protection offered to this species (spatio-temporal restrictions on acquisition within the BW BIAs and the 7 km Extended Shut-down Zone) is high. If a BW/PBW mother-calf pair is detected, the 7 km Shut-down Zone will protect these individuals from behavioural disturbance and the 32 km relocation requirement post shut-down will mean that hearing injury will be avoided. These control measures are considered to provide sufficient protection to BW/PBW mother-calf pairs, noting that a higher level of protection is afforded to SRW mother-calf pairs as the region is recognised as a calving location and very young calves could be present.	No

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Use of an additional vessel for the specific purpose of marine mammal monitoring.	P = No E = Limited Effectiveness	Having another vessel specifically dedicated to marine mammal monitoring (with MFOs and a PAM system onboard) could provide additional capacity for detecting whales at greater distances than from the Seismic Vessel. In this respect a dedicated marine mammal monitoring vessel would provide a high level of support to the extended Precaution Zones outlined in this EP. However, instead of using an additional vessel that is dedicated to marine mammal observations, all Extended Observation Zones will be monitored using at least one Support Vessel as an additional observation platform with two MFOs onboard. Aerial surveys will also be required prior to any acquisition in the BW/PBW BIAs/buffer and the SRW Ag BIA. On this basis, an additional and dedicated marine mammal monitoring vessel is not considered to be necessary as the proposed control measures that will be adopted sufficiently address the risks to marine mammals as quantified by underwater noise modelling. In addition, the adaptive management measures that will be implemented also serve to manage risk to marine mammals throughout the survey. Cost is grossly disproportionate to the environmental benefit gained from implementing the control measure.	No
Activation of a single low power acoustic source (mitigation gun) on line turns.	P = Yes E = Limited Effectiveness	The ongoing activation of a single low power acoustic source during line turns is often considered to reduce the likelihood of cetaceans approaching the Seismic Vessel during turns when the acoustic array is inactive (i.e. data acquisition is not occurring). While the use of a mitigation gun potentially assists by displacing marine fauna away from the acquisition area, the acoustic source will be completely shut down on line turns during the Otway Basin 3D MC MSS as 1) mitigation guns serve to increase the overall noise levels in the marine environment and 2) mitigation guns act in direct contradiction to the objectives of the BW Conservation Management Plan which specifically requires that blue whales are not displaced from foraging areas.	No
Implementation of shut downs for dolphins and pinnipeds.	P = Yes E= Effective	A small shut-down zone (e.g. 100 m) for dolphins is sometimes implemented around the active acoustic source as a precaution to address the purpose of the Australian Whale Sanctuary that cetaceans are not killed, injured, or interfered. TGS considered this approach for dolphins and otariid seals and rejected it on the basis that while dolphin or fur seal/se lion presence in the immediate vicinity of the Seismic Vessel is expected, it will be transitory (typically < 1 hour) and will certainly be less than the 24 hours for which TTS and PTS predictions apply. For dolphins (HF cetaceans) and otariid seals, the onset distance for TTS_{24h} is 100 m, and PTS is not predicted for dolphins or otariid seals (either from cumulative exposure or exposure to a single pulse). Cost (in terms of operational downtime) is grossly disproportionate to the environmental benefit gained from implementing the control measure.	No
Extended pre-start observation period.	P = Yes E = Limited Effectiveness	TGS recognises that by increasing the duration of pre-start visual observations, detectability rates of some marine fauna may increase. On this basis and due to the potential presence of deep/long diving cetacean species such as sperm whale and beaked whales, extending pre-start observations from 30 minutes to 45 minutes was considered. However, this control measure will not be implemented for the following reasons: a) the species identified as deep/long diving cetacean species are HF odontocete species for which modelling predicts that PTS will not occur from exposure to either a single pulse or cumulative exposure over 24 hours. For high-frequency species, TTS is also not predicted to occur from exposure to a single pulse and the onset distance for cumulative TTS is limited to within 100 m of the source; b) the acoustic source is moving continuously at a speed of ~8km/hr and therefore commencing observations earlier would include waters ~4 km further away from where acquisition is planned, meaning tangible benefits to individual species in the acquisition zone are limited; and c) For BW/PBW which are the species expected at greatest densities during the Seismic Survey, 30 minutes of pre-start observations is sufficient based on the following dive times as published by Owen *et al*. (2016) for pygmy blue whales off WA: - Feeding dives mean duration 7.6 min (max. 17.5 min) - Migratory dives mean duration 5.2 min (max. 26.7 min) - Exploratory dives mean duration 8.6 min (max 22.05 min) Cost is grossly disproportionate to the limited environmental benefit gained from implementing the control measure	No

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Acoustic source model validation.	P = No E = Limited effectiveness	UAM results are extensively used to inform suitable control measures for various receptors (including blue whales/pygmy blue whales) throughout this EP. While it is often considered best practise to undertake a programme of in-field noise measurements at relevant distances from the source to verify the accuracy of model predictions, in practise, this approach can be extremely challenging from both a scientific and logistical perspective. For the proposed Otway Basin 3D MC MSS, the impact assessment has relied extensively upon UAM conducted by JASCO of the 3,480 in^3 acoustic source with a far-field source specification of 248.9 dB re 1 µPa m PK and 225.1 dB 1 $\mu Pa^2 m^2 s$ SEL (10 – 2,000 Hz) in the broadside direction (see **Appendix B** for the UAM report). Predictions from JASCO's Airgun Array Source Model and propagation models have been extensively validated by JASCO globally against underwater acoustic measurement programs in different marine environments from Australia, the United States, Canada, Greenland and Russia (e.g. Hannay and Racca 2005; Aerts *et al.* 2008; Funk *et al*. 2008; Ireland *et al*. 2009; O'Neill *et al*. 2010; Warner *et al*. 2010; Racca *et al*. 2012a, 2012b; Matthews and MacGillivray 2013; Martin *et al*. 2015; Racca *et al.* 2015; Martin *et al*. 2017a, 2017b; Warner *et al.* 2017; MacGillivray 2018; McPherson *et al*. 2018). The large number of measurement programs conducted by JASCO across a range of environments has allowed for a rigorous assessment of the performance of acoustic source and propagation models, and a process of continued improvement to be in place. The models used by JASCO to generate the predictions of underwater noise that underpin this EP are consistently found to be reliable and robust. This provides confidence in the impact assessment which was based on the acoustic modelling results. It is noteworthy that, a verification study for four different acoustic sources in Australian waters found that measured data showed good agreement with the modelling in all cases (McPherson *et al*. 2018). This validation study used fixed loggers on the seafloor which are far superior to streamer-based measurements that have been used previously for the collection of in-field measurements during seismic surveys. With regards to the acoustic array sound source specifications, there is little to no uncertainty in the source model when the acoustic array is a standard type (MacGillivray 2018; McPherson *et al.* 2018). JASCO has confirmed that the proposed acoustic source for the Otway Basin 3D MC MSS fits this description. If the final acoustic source selected for the Otway Basin 3D MC MSS differs to that which was modelled in **Appendix B**, then additional source modelling will be undertaken to confirm whether the sound levels are consistent with levels assessed as acceptable in this EP. Cost is grossly disproportionate to the limited environmental benefit gained from implementing the control measure.	No
Alternative line sequencing to a 'race track' design to avoid sequential lines.	P = No E = Effective	If an alternative line turn sequencing programme was implemented, it could double the line change time. This results in the duration of the survey would be for a lot longer, which has other implications with other marine users and peak-foraging season. With the duration of the survey increasing, this means that the crew are out on the vessel for longer, which can increase HSE exposure and potential conflict with other water users. In addition, increasing the duration of the survey increases the costs to the programme significantly. Cost is grossly disproportionate to the environmental benefit gained from implementing the control measure	No
Alternative methods for detecting marine mammals other than PAM and visual observations (i.e. Active Acoustic Monitoring, and Radio Detection and Ranging (**RADAR**)).	P = No E = Limited/ Unknown Effectiveness	Visual sightings methods using MFOs are restricted to daylight hours and relatively good weather conditions and can only detect whales at the sea surface. Therefore, any additional method for detecting marine mammals during poor sighting conditions would be beneficial, especially during night-time operations and detection of submerged animals. Alternative detection methods include PAM, Active Acoustic Monitoring, and RADAR. TGS will utilise PAM on the Seismic Vessel during the Otway Basin 3D MS MSS. PAM will be operational 24 hours per day while the acoustic source is active and will be continuously monitored by an experienced PAM Operator. Classification to species level from the acoustic detections can only be reliably achieved using PAM, as all other detection methods have not yet been commercially proven or validated (including for detection distance) (Verfuss *et al*., 2018). PAM provides the most cost effective and reliable method to complement visual sightings, despite its limitations for detecting some low frequency vocalisations. Cost is grossly disproportionate to the limited environmental benefit gained from implementing the control measure	No

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Thermal imaging camera trial.	P = Unknown E = Limited/ Unknown Effectiveness	If available, TGS will trial thermal imaging camera technology to assess its effectiveness to detect large cetaceans during night time. The reliability and accuracy of thermal imaging technology for the use of detecting cetaceans at sea is currently unproven and distance estimates for detections made with the thermal imaging camera will need to be verified against concurrent PAM detections and distance estimates. Should thermal imaging be found to provide reliable detection and distance estimates during one phase of the survey, TGS will commit to using the technology on the Seismic Vessel during subsequent survey phases and will engage additional MFO resources to cover night shifts.	Yes
Prohibition of night-time operations.	P = No E= Effective	Under the standard management procedures for all whales, night-time operations may occur provided that there have not been three or more whale instigated power-down or shut-down situations during the preceding 24-hour period. Decisions on the requirement for this control will be made daily, i.e. at dusk each day, the MFO on-duty will advise whether the threshold of three whale instigated shut-downs was reached in the preceding 24 hours and will therefore confirm if night-time operations can occur. The same applies for low visibility operations where decisions on whether to continue operating will be made each time low visibility conditions arise. For BW/PBW and SRWs, a slightly more conservative approach is proposed as follows: • Low Visibility or Night-time Operations may occur provided that no BW/PBW shut downs have been instigated during the preceding 24 hours within 32 km of the planned acquisition (i.e. the survey lines that will occur during the hours of darkness or the period of low visibility); however Low Visibility and Night Time Operations inside the BW BIAs/buffer are contingent on aerial surveys occurring within 7 days prior to acquisition occurring here. • Low Visibility or Night-time Operations may occur provided the no SRW shut downs have been instigated during the preceding 24 hours within 42 km of the planned acquisition (i.e. the survey lines that will occur during the hours of darkness or the period of low visibility); however Low Visibility and Night Time Operations inside the SRW Ag BIA/buffer are contingent on aerial surveys occurring within 7 days prior to acquisition occurring here. While excluding night time operations would reduce the probability of a cetacean occurring within the Shut-down Zones without being detected, this approach would double the amount of time and the cost required to acquire the same amount of seismic data. Given the already limited windows for acquisition when accounting for potential weather downtime, and the significant number of seasonal environmental sensitivities, it may not be possible to completed acquisition of individual survey phases if night-time operations do not occur. The control measure of no night-time operations is not considered practicable, as it will result in extending the duration of the overall survey.	No
Use of drones or unmanned aerial vehicles (**UAV**).	P = No E = Limited	The capability of drones in offshore environments is limited by battery life, the distance they can travel and to low wind conditions (~<20 knots). The battery life of UAV's is longer, and they are capable of travelling longer distances, but are still limited to wind conditions of <25 knots. An experienced pilot is needed to operate an UAV and the costs associated with this in an offshore environment are likely to be c. $700/day, excluding the cost of drone hire. It is considered that there would be limited benefit of using a drone/UAV over visual observation by MFOs as both are best suited to optimal conditions. As such, the costs associated with using drones or UAVs to observe for whales are considered to be grossly disproportionate to the benefits gained.	No
Use of acoustic detection systems (e.g. Autonomous Underwater Vehicles, Autonomous Surface Vehicles, moored acoustic systems) for detection of the arrival of pygmy blue whales into the pygmy blue whale foraging BIAs.	P = No E = Unknown Effectiveness	In addition to PAM, other systems for acoustic detection of whales and other cetaceans could be used to increase the ability to detect and avoid animals during the Otway Basin 3D MC MSS. All of these systems have limitations. Moored systems have been successfully used to record acoustic data in the vicinity of the Bonney Upwelling (McCauley *et al.,* 2018; Jolliffe *et al*., 2021), but this did not include real-time or near-real-time access to the data and could not be used for mitigation purposes. Close to real-time monitoring has been implemented from a moored system using surface buoys transmitting data via an Iridium/GPS antenna to mitigate impacts on northern right whales (Baumgartner *et al*., 2019), but this system relies on bespoke stretch hoses and mooring buoys that have highly limited availability and significant costs to install and maintain, and the system is restricted to monitoring in the vicinity of the mooring; detecting whales across significant areas within or adjacent to the pygmy blue whale foraging BIAs is not considered practicable.	No

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
		Autonomous Underwater Vehicles and Autonomous Surface Vehicles can be used to detect vocalising whales and dolphins; however, such systems are currently restricted to presence/absence information rather than being able to localise or accurately detect the range to animals. These systems also require significant costs associated with leasing or buying equipment, piloting the systems, and data processing. If used in conjunction with aerial surveys, these systems could provide some additional ability to detect whales and other cetaceans, but the limited availability of equipment and costs associated with implementing these systems outweighs the benefit provided.	
Use of remote sensing data or moored loggers for detection of upwelling sites and potential feeding aggregations (e.g. sea surface temperature, chlorophyll-α) for detection of the arrival of pygmy blue whales into the pygmy blue whale foraging BIAs.	P = No E = Unknown Effectiveness	Remote sensing data or data from moored loggers of environmental parameters could be used to predict upwelling locations and subsequent food sources for blue whales and other marine mammals. Although such data could provide an early indication of the onset of the upwelling season, and therefore help to predict timing of cetaceans arriving in the region to forage, the use of such data to predict whale presence at a fine scale is more limited. Gill *et al*. (2011) noted the first blue whales arriving approximately one week after the onset of upwelling in 2003 and 2004. However, data cannot always be accessed in real-time and upwelling itself does not necessarily equate to cetaceans being present at any given location. In addition, Gill (2023; pers. comm) has indicated that individual upwelling episodes are unlikely to be predictive of PBW presence, rather cumulative upwelling presence influences PBW distribution over the following 12 months; hence there are uncertainties around the interpretation of any upwelling data in relation to PBW distribution. These limitations outweigh any potential benefits.	No
Avoidance of spawning times for commercially targeted fish and crustacean species.	P = No E = Fairly effective	Many fish species within the OA are widely distributed and have extended spawning periods in which they spawn multiple times. Combined spawning periods for the key target species covers most months of the year, and therefore the survey could not be acquired if all spawning periods were avoided. Fish spawning periods were considered in detail as part of the planning process for the Otway Basin 3D MC MSS, noting the importance of spawning and recruitment of fish stocks, but also noting fishes' sensitivity to seismic source is significantly less than that of cetaceans. Significant disturbance to groups of spawning fishes may occur for short periods when the acoustic source passes within hundreds of meters of their location. The spawning periods of the many different key species for the commercial fisheries in the region extent throughout the majority of the year but can vary significantly between species. Most species are highly fecund and spawn over protected spawning periods, thus naturally offsetting potential natural or anthropogenic mortalities. Occasional localised disturbances of groups of spawning fishes may occur, but this is not expected to have a significant impact on stocks due to their high fecundity, protracted spawning periods, biological connectivity through recruitment from across the region, as well as large natural variability in the spawning biomass and recruitment levels. Avoidance of fish spawning periods would provide limited additional environmental benefit at a disproportionate cost (in terms of potential impacts to more sensitive marine fauna and costs associated with additional measures that would likely be required for whales such as additional shut-downs, adaptive management, etc.). Further constraining the survey window and limiting the overlap of the survey with fish spawning periods may mean that the proposed Otway Basin 3D MC MSS could not be completed, therefore this option is not considered practicable.	No
Seismic activities will be restricted to areas outside key commercial fishing areas/seasons.	P = No E = Effective	This would potentially avoid overlap with the commercial fishing operations identified during the consultation programme with relevant persons and the fisheries assessment undertaken. Best efforts have been made to avoid fisheries where possible; however, there will be some overlap, and this will be managed through control measures and ongoing communication for the duration of the survey to minimise conflict and disturbance. TGS will consider adjusting sail lines to accommodate commercial fishers' requests (see below).	No
No operation of the acoustic source within the UXO SDC006 Acoustic Exclusion Area.	P = Yes E = Effective	The potential for seismic emissions to damage the casings containing the mustard gas was raised during consultation with relevant persons, therefore, as a precautionary control measure around UXOs, TGS will implement an Acoustic Exclusion Area of 3 NM around the centre point of UXO site SDS006 within which there will be no activation of the acoustic source (**Figure 84**). This site was an area of chemical munitions dumping (mustard gas).	Yes
A BACI study is implemented prior to the Otway Basin 3D MC MSS commencing.	P = No E = Effective	Developing and completing a BACI study for the active fisheries within and surrounding the OA is a significant undertaking and would need to occur over a long period of time to assure that the methodology and results were robust, representative and consider the inherently high level of natural variability present.	No

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
		Many studies have been undertaken on the effects of fish and their response to seismic emissions, with many reporting that fish typically move away from a loud acoustic source if they are uncomfortable with the noise, thereby minimising their exposure and the potential for any deleterious effects. Most studies that are undertaken on fish are essentially represented as worst case scenarios, as the fish are not able to move away from the acoustic source like they can in the wild. The costs of such an extensive BACI study would be grossly disproportionate to the environmental benefit gained from implementing such a control measure.

ALARP Statement			
The decision context has been assessed as Type B for all receptors. The corresponding residual risk rankings have been determined to range from **Negligibl**e to **Moderate**. TGS considers the adopted control measures appropriate to manage the impact from acoustic disturbance to the marine environment associated with the Otway Basin 3D MC MSS. The proposed control measures have been developed in accordance with the legislative requirements, good industry practice, using professional experience and taking into account the specific environmental, social, economic and cultural characteristics of the OA and predicted impacts to other marine users. Alternative and additional control measures were considered, and implemented where effective and practicable, as part of the assessment process. No further additional or alternatively controls were identified. Therefore, the predicted impacts to receptors from acoustic disturbance to the marine environment during the Otway Basin 3D MC MSS are reduced to **ALARP.**			

7.2.6 Impact and Risk Acceptability

Table 85 Demonstration of General Impact and Risk Acceptability for Acoustic Disturbance to the Marine Environment

Context	Acceptability Summary
Residual Risk Ranking	The Residual Risk has been determined to range from **Negligible** to **Moderate**
Ecologically Sustainable Development	There is no threat of serious or irreversible environmental damage or significant impact to biological diversity and ecological integrity associated with underwater sound emission from the acoustic source during the Otway Basin 3D MC MSS. The aspect and potential interactions are well understood and managed in accordance with applicable industry standards and industry good practice. Therefore, the impact is considered to be consistent with the principles of ESD.
TGS's Internal Context	The proposed management of the risks associated with the establishment of IMS is consistent with TGSs QHSE Policy commitments of: • Protecting the environment; and • Conducting operations in an environmentally sustainable and responsible manner.
Existing Environmental Context	The OA overlaps with BIAs for the following species: whale sharks, BW/PBW, SRW, wedge-tailed shearwater, short-tailed shearwater, wandering albatross, Antipodean albatross, Australasian gannet, white faced storm petrel, common diving petrel, Buller's albatross, shy albatross, Indian Ocean yellow-nosed albatross, black browed albatross, and Campbells albatross. While numerous commercially valuable fish stocks occur in the region, by far the majority of fishing effort occurring inshore of the OA. Based on the UAM results, the maximum residual risk ratings for all animal groups were assessed as **Low**, with the exception of marine mammals. A **Moderate** residual risk rating for behavioural effects and perceptual effects was reported for marine mammals. The OA directly overlaps with two AMPs; the Nelson AMP and the Zeehan AMP which are classified IUCN VI. The OA overlaps with one KEF being the West Tasmania Canyons. Environmental sensitivities within each AMP and KEF have been individually taken into consideration within the EP. Based on the UAM results, the maximum residual risk ratings for all these protected and sensitive areas were assessed as **Low**. Overall, it is considered that through the implementation of the proposed control measures (including precaution zones, MFOs, temporal and spatial measures and adaptive management measures), and the associated operational procedures, the impacts from underwater noise emissions from the Otway Basin 3D MC MSS will not have any serious, long-term or irreversible impacts to ecology or socio-economic values. The Seismic Vessel, and associated acoustic source, will be constantly moving at a speed of 4.5 knots during acquisition. The proposed acoustic source size of 3,480 in^3 is consistent with that used in contemporary MSSs for which there have been little, if any, reported deleterious effects. Therefore, the impacts to the existing environment and identified receptors are likely to be short-term, localised, and rapidly recoverable.
External Context – Management Plans, Species Recovery Plans and Conservation Advice	The residual risk of the acoustic disturbance to the marine environment has been determined to range between Negligible to Moderate and will not have a significant impact on a matter of national environmental significance in accordance with Policy Statement 1.1. The NOPSEMA guidance note for petroleum activities and Australian Marine Parks (Guidance Note N-04750-GN 1785 A620236) requires that an EP is developed for undertaking activities such as MSSs to evaluate how environmental impacts and risks will be of an **Acceptable Level** and reduced to **ALARP** and demonstrate that the MSS will not be inconsistent with the relevant marine park management plan. The OA for the Otway Basin 3D MC MSS overlaps with the Nelson AMP and Zeehan AMPS. Despite this, the Otway Basin 3D MC MSS will be undertaken in accordance with the objectives of the South-east Commonwealth Marine Reserves Network Management Plan 2013–2023. Each of the environmental sensitivities within the AMPs have been assessed within this EP, where the management of the Otway Basin 3D MC MSS is considered to be consistent with the objectives of the management plan. The relevant measures within the conservation advice and recovery plans have been considered during the development of the control measures that will be implemented during the Otway Basin 3D MC MSS and are considered to be consistent with these recovery plans and conservation advice as described below.

Context	Acceptability Summary
	Conservation Management Plan for the Blue Whale Interim Objective 4 of the 'Conservation Management Plan for the Blue Whale' is to "*ensure anthropogenic threats are demonstrably minimised*" and is to be tested by Target 4-1; "*Robust and adaptive management regimes leading to a reduction in anthropogenic threats to Australian blue whales are in place*". This Conservation Management Plan listed seismic noise as a potential source of anthropogenic noise impacts, which was determined a threat with very high priority for pygmy blue whales. Listed conservation actions to ensure recovery targets are met that are applicable to the Otway Basin 3D MC MSS include: • Assessing the effect of anthropogenic noise on blue whale behaviour; • Anthropogenic noise in BIAs will be managed such that any blue whale continues to utilise the area without injury, and is not displaced from a foraging area (where 'foraging area' is defined in the 'Guidance on key terms within the Blue Whale Conservation Management Plan'; DAWE, 2021) as any designated foraging BIA); and • Policy Statement 2.1 is applied to all MSSs. The effects of anthropogenic noise on PBWs have been assessed in this EP. Animat modelling was undertaken to understand the specific injury and disturbance risk that the Otway Basin 3D MC MSS poses to PBWs. This modelling incorporated PBW movement data to predict exposure ranges that are significantly more realistic than those produced by UAM. Animat modelling predicted that the maximum distance within which 95% of threshold exceedances would occur for PBW is 130 m for PTS (SEL_{24h}) and 32 km for TTS (SEL_{24h}). Cumulative TTS effects from acquisition on the continental slope are however only expected to occur to c.16 km inshore of the active acoustic source on account of reduced sound propagation in the upslope direction. The 16 km onset distance for cumulative TTS in the inshore direction has been used to define a buffer zone around all of the BW BIAs in the vicinity of the OA. No acquisition will occur within these BIAs or the associated buffer during the 'peak feeding season' from January to June (inclusive) based on the expected consistent and widespread presence of whales in the foraging areas during these months (Gill *et al.*, 2011; 2015; McCauley *et al*., 2018). The only exception to this is the acquisition of the 2D tie line which will be subject to additional operational restrictions (see **AMP 2** in **Appendix M**) and will only take approximately 12 hours to acquire. This spatio-temporal measure has been designed to eliminate any physical or behavioural effects on foraging BW/PBW in the designated BW BIAs during the foraging season; hence, to comply with the requirement of the BW Conservation Management Plan that BWs can continue to use biologically important areas without injury and no BW will be displaced from a foraging area. On this basis, the protection afforded to BW/PBW in the BW BIAs is very strong during the peak months of foraging area use. Operations inside the BW BIAs and the 16 km buffer will be permitted outside these months including during the 'foraging shoulder season' months of September to December and July when whales may be present, but densities are expected to be substantially lower and presence is less consistent. All operations inside the BW BIAs/buffer during the foraging shoulder season will be subject to the use of aerial surveys to assist with BW/PBW detection. Throughout the entire OA and for the full duration of the Otway Basin 3D MSS an Extended Observation Zone[AC] will be implemented to detect BW/PBWs at extended distances from the seismic source and a 7 km Extended Shut-down Zone[AC] for BW/PBW will be adopted. Where 7 km represents the maximum predicted onset distance for behavioural effects for BW/PBW. The adoption of the 7 km Extended Shut-down Zone for BW/PBW will therefore minimise behavioural impacts and prevent the displacement of BW/PBWs from foraging areas inside and outside of the designated BW BIAs. In addition, the 32 km maximum predicted onset distance for TTS has also been utilised in defining several control measures for BW/PBW to manage 1) Seismic Vessel relocations following shut-downs, and 2) the ability for night-time/low visibility operations to occur. In addition, several adaptive management measures will be implemented if higher than anticipated numbers of BW/PBW are encountered. In summary, adoption of Policy Statement 2.1 Part A measures and several Part B measures including the implementation of additional control measures throughout the OA will ensure that BW/PBW will be able to utilise the BIA and surrounds without injury or significant behavioural impacts whilst the Otway Basin 3D MC MSS takes place, and the control measures that TGS will implement are consistent with the required conservation actions for BWs. Based on the proposed control measures (including the temporal and spatial mitigations to be implemented, the 7 km Extended Shut-down Zone and several adaptive management measures), and the species specific Animat modelling to quantify potential impacts, the overall environmental risks from the Otway Basin 3D MC MSS are considered to be reduced to **ALARP** and at **Acceptable Levels** with regard to BW/PBWs and that management of the Otway Basin 3D MC MSS aligns with the objective of the BW Conservation Management Plan. **Conservation Management Plan for the Southern Right Whale** Interim Recovery Objective 5 of the Operative SRW Conservation Management Plan (CoA, 2012) requires that "*Anthropogenic threats are demonstrably minimised*" in accordance with Target 5.1 that requires "*robust and adaptive management regimes leading to a reduction in anthropogenically-induced southern right whale mortality in Australian waters are in place*" and Target 5.2 that requires that "*management decisions are supported by high quality information and high priority research targets identified in this plan are achieved or underway by 2021*". Listed conservation actions to ensure recovery targets are met that are applicable to the Otway Basin 3D MC MSS include: • Assessing anthropogenic noise in key calving areas; • Assessing responses of SRWs to anthropogenic noise; and • If necessary, developing further mitigation measures for noise impacts. The operative SRW Conservation Management Plan also states that "*noise interference is of particular concern within or close to SRW aggregation areas where young calves are present and whales are resident for long periods of time*"; hence control measures that will be implemented during the Otway Basin 3D MC MSS for this species have been designed to address these specific noise impacts. The operative SRW Conservation Management Plan also recognises that "*noise may also deter whales from establishing aggregations in otherwise suitable but currently unused habitat and disrupt migratory movements, thereby preventing individuals from using preferred habitats*". While there is another designated 'known core range' BIA in the area, the OA only marginally overlaps with this, and the expectation is that animals traverse this area on their way to and from the more coastal aggregation areas and connecting habitat. Strong adaptive management measures have been developed to address potential noise effects in the wider area; hence to minimise impacts on migrating SRWs.

Context	Acceptability Summary
	The effects of anthropogenic noise on SRWs have been assessed in this EP. Animat modelling was undertaken to understand the specific injury and disturbance risk that the Otway Basin 3D MC MSS poses to SRWs (both mother-calf pairs and all other cohorts). This modelling incorporated SRW movement data to predict exposure ranges that are significantly more realistic than those produced by UAM. Animat modelling predicted that the maximum distance within which 95% of threshold exceedances would occur for SRWs is 40 m for PTS (SEL_{24h}) and 11 km for TTS (SEL_{24h}). Based on these results, TTS effects are not predicted to extend from the OA into the Aggregation BIA (which occurs 14 km north of the OA) or any of the connecting habitat, migration and resting on migration BIAs that occur further afield in coastal waters. The predicted onset distance for behavioural effects for SRWs were assessed separately for 'mother-calf pairs' and 'other individuals' as 31.5 km and 6.1 km respectively. In addition to the Animat modelling results the maximum-over-depth acoustic modelling results indicate that the 140 dB (SPL) behavioural effects threshold may indeed be exceeded approximately 42 km inshore of acquisition on the continental shelf. Hence behavioural effects on mother-calf pairs could occur in the SRW Ag BIA. The 42 km onset distance for behavioural effects for mother-calf pairs has been used to define a buffer zone around the SRW Ag BIA that lies inshore of the OA. No acquisition will occur within this BIA or the associated buffer during the during the core aggregation months of May to September. The only exception to this is the acquisition of the 2D tie line which will be subject to additional operational restrictions (see **AMP 2** in **Appendix M**) and will only take approximately 12 hours to acquire. This spatio-temporal measure has been designed to eliminate any physiological or behavioural effects on SRWs in the SRW Ag BIA during the months over which SRWs are expected to be present. On this basis, compliance with Interim Recovery Objective 5 of the operative SRW Conservation Management Plan that anthropogenic threats are demonstrably minimised, is achieved. This control also aligns with the recommendation that seismic surveys should be undertaken outside of biologically important areas at biologically important times. The adoption of these controls ensures that the protection afforded to SRWs in the SRW Ag BIA is very strong during the core aggregation period. Operations inside the SRW Ag BIA and the 42 km buffer will be permitted outside these months including during the aggregation shoulder months of April and October. All operations inside the SRW Ag BIA/buffer during the shoulder months will be subject to the use of aerial surveys to assist with SRW detection. Throughout the entire OA and for the full duration of the Otway Basin 3D MSS an Extended Observation Zone[AC] will be implemented to detect SRWs at extended distances from the seismic source and a 7 km Extended Shut-down Zone[AC] for SRW will be adopted. In keeping with the Shut-down Zone with BW/PBW, 7 km has been selected as the Shut-down Zone for SRW, to conservatively address the maximum predicted onset distance of 6.1 km for behavioural effects on individual (i.e., unaccompanied) SRWs. The adoption of the 7 km Extended Shut-down Zone for SRW will therefore minimise behavioural impacts both inside and outside of the designated SRW Ag BIA and throughout the 'known core range' BIA. In addition, the 42 km maximum predicted onset distance for behavioural effects on mother-calf pairs has also been utilised in defining several control measures for SRWs to manage 1) Seismic Vessel relocations following mother-calf pair instigated shut-downs, and 2) the ability for night-time/low visibility operations to occur. In addition, several adaptive management measures will be implemented if higher than anticipated numbers of SRW are encountered. In summary, adoption of Policy Statement 2.1 Part A measures and several Part B measures (as summarised above) will ensure that SRWs will be able to utilise the OA without injury or significant behavioural impacts whilst the Otway Basin 3D MC MSS takes place and ensures consistency with the objective of the SRW Conservation Management Plan (that anthropogenic threats are demonstrably minimised) is achieved. Hence, the control measures that TGS will implement are consistent with the required conservation actions for SRWs in the operative SRW Conservation Management Plan. While the Draft National Recovery Plan for the Southern Right Whale (CoA, 2022) is not yet operative, once finalised it will supersede the operative conservation management plan. The conservation actions included in the draft plan have also been considered in this EP (see **Table 79**) and are also addressed by the proposed controls. Based on the proposed control measures (including the temporal and spatial mitigations to be implemented, the 7 km Extended Shut-down Zone and several adaptive management measures), and the species specific Animat modelling to quantify potential impacts, the overall environmental risks from the Otway Basin 3D MC MSS are considered to be reduced to **ALARP** and at **Acceptable Levels** with regard to SRWs and that management of the Otway Basin 3D MC MSS aligns with the objective of both the operative SRW Conservation Management Plan and the Draft National SRW Recovery Plan. For all other species of baleen whale, conventional UAM results predicted that 24-hour cumulative PTS could occur out to a maximum of 500 m, but that exposure to a single pulse from the active acoustic source would not elicit PTS even if an animal was very close to the source (< 20 m) (**Table 70**). The maximum onset distance for 24-hour cumulative TTS is predicted to be 156 km while the single pulse onset distance for TTS is 70 m. On the basis that other baleen whales are probably only present in the OA at low densities (see **Table 25**) and that UAM does not account for animal movement or the movement of the Seismic Vessel, the 24-hour cumulative UAM results were considered to be excessively conservative for defining the extent of observation or shut-down zones for other baleen whales. It is noteworthy that over a 24-hour period the Seismic Vessel could travel up to 200 km; hence 24-hour cumulative exposure over the 156 km TTS onset distance and the 500 m PTS onset distance is unlikely for baleen whales. As a precaution, an Extended 2 km Shut-down Zone for all other whales will be adopted throughout the OA and this will serve to provide complete protection from short-term exposure to underwater noise for these species. In addition, adaptive management measures will be implemented to provide further protection to these other species of whale. **<u>Approved Conservation Advice for *Megaptera novaeangliae* (humpback whale):</u>** Conservation and Management Actions for humpback whales have been outlined in the Humpback Whale Conservation Advice and include "*assessing and addressing anthropogenic noise: shipping, industrial and seismic surveys*". All mitigation measures listed within the Conservation Advice are included within the proposed control measures and will be implemented throughout the Otway Basin 3D MC MSS, this also includes the adoption of all Policy Statement 2.1 Part A measures and certain Part B measures (including extended Precaution Zones, use of MFO, spatial and temporal adaptive management procedures, such as limits on night-time/low visibility operations and vessel location in certain circumstances, and the use of PAM), and the undertaking of UAM. The mitigation measures in place for the Otway Basin 3D MSS will adhere to the requirements of the Conservation Advice and will assist with reducing potential noise impacts and risks to **ALARP** so that any potential impacts are managed to an **Acceptable Level** with regard to humpback whales and that the Otway Basin 3D MSS will be carried out in a way that will be consistent with the Humpback Whale Conservation Advice. **<u>Conservation Advice for Sei and fin Whales</u>** No further mitigation measures have been provided in the Conservation Advice for sei and fin whales to address anthropogenic noise; however, those mitigations adopted to address potential impacts on BW/PBW will be of substantial benefit to sei and fin whales given their feeding association with the regional upwelling system as well. Adoption of Policy Statement 2.1 Part A measures and several Part B measures will be implemented to reduce the potential noise impacts and risks to **ALARP** and **Acceptable Levels** with regard to sei and fin whales, and the survey will be consistent with the Conservation Advice for these species. **<u>Conservation Advice for the Australian sea lion</u>:** The Conservation Advice for Australian sea lions recognises that exposure to sharp, short sounds of moderate intensity for extended periods (e.g. from MSSs) may cause avoidance behaviour and/or hearing threshold changes in pinnipeds. Seismic pulses may also affect bony fish which pinnipeds feed on. No standards for managing noise impacts from MSSs (or other noise sources) are specified. The impact assessment has demonstrated that no significant or long-term disturbance or injury to Australian sea lions is predicted, and the level of impact and risk is considered to be acceptable. **<u>Conservation Advice for the Australian sea lion</u>:**

Context	Acceptability Summary
	The Conservation Advice for Australian sea lions recognises that exposure to sharp, short sounds of moderate intensity for extended periods (e.g. from MSSs) may cause avoidance behaviour and/or hearing threshold changes in pinnipeds. Seismic pulses may also affect bony fish which pinnipeds feed on. No standards for managing noise impacts from MSSs (or other noise sources) are specified. The impact assessment has demonstrated that no significant or long-term disturbance or injury to Australian sea lions is predicted and the level of impact and risk is considered to be acceptable. **Recovery Plan for Marine Turtles in Australia (Commonwealth of Australia 2017)** Although the impact of anthropogenic activities, specifically anthropogenic noise, has been identified within the Recovery Plan for Marine Turtles in Australia, there are few specific requirements with regard to management actions which may address effects on marine turtles. The OA for the Otway Basin 3D MC MSS does not overlap with any areas identified as BIAs for marine turtles and high numbers of marine turtles are not expected to be encountered during the Otway Basin 3D MC MSS. As a precaution, TGS will adopt several control measures to ensure the Otway Basin 3D MC MSS is sufficient to meet the requirements of, and undertake the activity consistent with, the Recovery Plan for Marine Turtles in Australia (Commonwealth of Australia 2017). In particular, TGS will adopt a precautionary 100 m Shut-down Zone from the operating acoustic source for marine turtles whereby the acoustic source will be shut-down, or start-up will be delayed for 15 minutes if a marine turtle is observed within the 100 m Shut-down Zone. Operation of the acoustic source using soft-starts may only resume when the turtle has been observed to move outside the 100 m Shut-down Zone, or when 15 minutes have lapsed since the last turtle sighting. Tail buoys on the streamers will also be fitted with turtle guards, of be of a design that does not pose an entrapment risk to marine turtles. **Draft Wildlife Conservation Plan for Seabirds 2019** Under the Draft Wildlife Conservation Plan for Seabirds 2019, effects of anthropogenic disturbance to seabird breeding and roosting areas are to be managed. Given the open ocean nature of the Otway Basin 3D MC MSS no disturbance effects from underwater noise are predicted for breeding or roosting sites therefor no specific additional measures are required to reduce potential noise impacts and risks to **ALARP** and **Acceptable Levels** for seabirds. **Recovery plan for the White Shark (*Carcharodon carcharias*)** The Recovery Plan for the White Shark does not identify sound as a threat to the species. Acoustic emission impacts from the Otway Basin 3D MC MSS are not predicted on white sharks. Actions are considered consistent with the objective of facilitating recovery of white sharks. **AMP Values, Management Prescriptions and IUCN Reserve Management Principles** No population level impacts or serious or irreversible ecological implications to AMPs within the OA are predicted to occur as a result of acoustic disturbance to the marine environment. Therefore, the biological diversity and sustainability of the AMPs are considered to be conserved. There are no predicted impacts to the ongoing sustainable use, where permitted, of the AMPs within the OA. The activity is consistent with the IUCN management prescriptions and permissible use of the AMPs. **Conservation values and objectives of the South-east Commonwealth Marine Reserves Network Management Plan 2013 – 2023** NOPSEMA Guidance Note "*Petroleum activities and Australian Marine* Parks' states that "*Petroleum activities may be allowable in Multiple Use Zones and Special Purpose Zones (IUCN category IV) subject to environmental approvals and demonstration that environmental impacts will be consistent with the relevant management plan"* and that "*Titleholders undertaking petroleum activities in Australian waters must ensure that any potential environmental impacts from the petroleum activities are managed to be consistent with the relevant management plan".* There are no predicted severe or long-term impacts to individual species or ecological populations as a result of the acoustic disturbance to the marine environment. Therefore, the biodiversity and ecosystem health of the SEMR Network is considered to be conserved. The predicted impacts are not inconsistent with the requirements of the Conservation Advice, Recovery Plans and Management Plans associated with the EPBC Act listed species identified. The activity is consistent with the goals and objectives of the South-east Commonwealth Marine Reserves Network Management Plan 2013 – 2023.
Social Acceptance – Relevant Person Expectations	Relevant persons have noted concerns regarding the potential for the survey to impact on SBTF fishing operations and interfere with the migration of SBT. Given the limited sensitivity of SBT to sound, behavioural effects will be localised and short term, and no impacts to migration are expected. Control measures have been proposed to manage seismic acquisition with the industry. Concerns have been raised regarding the impacts of seismic on primary productivity and the food web, commercial fishery catch rates and the SBT migration. Impacts to all have been assessed and the residual risk is considered to be low. Fishers in the TAS giant crab and rock lobster fisheries, raised concerns regarding to adults and larvae (recruitment). The exclusion of acquisition within water depths less than 1,000 m adjacent to the TAS fisheries was also requested. Noting that the TAS giant crab stock is currently assessed as depleted, TGS have adopted the requested exclusion. It was acknowledged that that the Otway Basin 3D MC MSS is mostly located offshore in deep waters that avoid most rock lobster fishing effort, but concerns were noted regarding the effects of seismic on rock lobster and rock lobster larvae. The relevant person also explained that some deep water fishing effort occurs occasionally for white lobster and requested that the survey be modified to avoid these areas. Although no such exclusion has been adopted by TGS for rock lobster, the AA already avoids depths and most areas where any fishing effort has previously occurred. The exclusion zone defined for TAS giant crab also has some indirect benefit in this respect for rock lobster. No significant impacts to rock lobster recruitment or to fishing activities is expected. Several relevant persons questioned TGS over potential compensation to commercial fishers who experience financial loss as a result of the Otway Basin 3D MC MSS. TGS has developed a commercial fisheries compensation protocol, whereby fishers who experience an economic loss as a result of damage to fishing gear, displacement, or loss of catch may lodge a claim for compensation to be assessed by a third-party independent assessor. This has been provided as **Appendix N** of this EP. One relevant person highlighted the potential utilisation of offshore waters and the STC for foraging PBWs. This has been factored into the assessment. TGS has developed the control measures for marine mammals (particularly SRW and BW/PBW) with relevant persons with expertise in blue whales and aerial surveys. Marine Parks Australia, on behalf of the Director of National Parks, responded during consultation with concerns on impacts to AMPs. Impacts to values of the AMP network will be managed such that there is no long term impact to the biological diversity and values of the AMPs. TAS relevant persons raised concerns on the potential disruption of foraging in sooty shearwaters/muttonbird; a species with cultural significance. Impacts to plankton have been assessed within this EP and it is considered that there will be no significant impacts to plankton communities and therefore knock-on effects on sooty shearwaters (and seabirds in general).

Context	Acceptability Summary
	Relevant persons also raised concerns regarding a WWII munitions dump site. TGS has implemented an exclusion area around this UXO dump site to ensure there will be no impacts to the integrity of the munitions casings from acoustic emissions. General concerns raised during the preparation for this EP included potential impacts on plankton/zooplankton, whales, SBT, and spawning. These potential impacts have all been assessed throughout this EP. All concerns raised by relevant persons were considered as part of the EP process and responses were provided to all submissions with further information or feedback as necessary. Results of the impact assessments have been summarised and provided to all relevant persons, when requested. Engagement with all relevant persons will continue for the duration of the EP. All submissions and associated response are provided in **Appendix H**. Detailed literature reviews and UAM were included in the development of the EP and an extensive set of control measures to reduce the overall impacts from the Otway Basin 3D MC MSS on the marine environment and those relevant persons that use the marine environment for their economic wellbeing, to **ALARP** and an **Acceptable Level**.
External Context – Commonwealth and State Legislative Criteria	The Otway Basin 3D MC MSS will comply with all relevant legislative requirements, in particular Policy Statement 2.1 Part A measures. Under Part B of Policy Statement 2.1, various measures are recommended when the likelihood of encountering whales is moderate to high. Several control measures will be implemented for the duration of Otway Basin 3D MC MSS in accordance with Part B of Act Policy Statement 2.1.
Industry Best Practice	The proposed control measures follow industry best practice and best practice guidelines, including: • Adoption of Policy Statement 2.1 which is considered Industry Best Practice for minimising the effects of MSSs on marine mammals. Control measures will be implemented for the duration of the Otway Basin 3D MC MSS and these measures have been developed in accordance with Policy Statement 2.1 (i.e. soft-starts, Precaution Zones, MFOs), as well as through discussion with experts in the field of marine mammals (i.e. Blue Whale Study). Where appropriate, TGS has provided increased protection for marine mammals above that which is required within Policy Statement 2.1, for example through the use of Extended Observation and Shut-down Zones, and aerial surveys; • Development of a Commercial Fisheries Compensation Protocol to ensure that seismic acquisition is undertaken in a manner that prevents any increased cost encumbrance or loss of income to commercial fishing licence holders. • The IAGC Environmental Manual for Worldwide Geophysical Operations which includes recommended mitigation measures for cetaceans to minimise acoustic disturbance during geophysical operations. These measures include, but are not limited to: • Use of Soft-start Procedures; • Providing basic awareness training to the entire crew; have them immediately report any cetacean observation to the bridge; • Reporting immediately to local authorities any animals in distress, animal carcasses, etc.; and • The APPEA Code of Environmental Practice which includes objectives to reduce the impact on cetaceans and other marine life to ALARP and to an Acceptable Level by ensuring operations are in accordance with legislative requirements and demonstrate the implementation of appropriate management measures.
ALARP	The decision context has been assessed as Type B for all receptors. The corresponding residual risk rankings have been determined to range from Negligible to Moderate. TGS considers the adopted control measures are appropriate to manage the impact from acoustic disturbance to the marine environment associated with the Otway Basin 3D MC MSS. The proposed control measures have been developed in accordance with the legislative requirements, good industry practice, using professional experience, and taking into account the specific environmental, social, economic and cultural characteristics of the OA and predicted impacts to relevant persons. Alternative and additional control measures were considered, and implemented where effective and practicable, as part of the assessment process. No further additional or alternatively controls were identified. Therefore, the predicted impacts to receptors from acoustic disturbance to the marine environment are reduced to **ALARP.**

Table 86 Demonstration of Specific Impact and Risk Acceptability for Acoustic Disturbance to the Marine Environment

Receptor	Relevant External Context	Defined Acceptable Level	Comparison with Predicted Levels of Impact	Acceptable
Plankton	Principles of ESD, specifically no serious or irreversible environmental damage and the conservation of biological diversity and ecological integrity.	Impacts to plankton communities are localised (within 100s of m from the acoustic source) and recoverable (< 1 week to recover). Note that the latter is considered sufficient to protect against population level impacts and impacts to the recruitment levels at surrounding habitats.	Overall, there is the potential for localised, short-term impacts to zooplankton as a result of the Otway Basin 3D MD MCC; however, population recovery is expected within days after the Otway Basin 3D MD MCC has ceased and no lasting ecosystem population impacts are expected.	Yes
Benthic Habitats	Principles of ESD, specifically no serious or irreversible environmental damage and the conservation of biological diversity and ecological integrity.	No detectable impacts to habitat forming benthic primary producers as a result of the Otway Basin 3D MC MSS.	The threshold value of 226 dB re 1 µPa PK was not reached at any of the modelled sites analysed within the UAM. Therefore, no detectable impacts to benthic habitat forming species such as sponges and corals are expected.	Yes

Receptor	Relevant External Context	Defined Acceptable Level	Comparison with Predicted Levels of Impact	Acceptable
Benthic Invertebrates	Principles of ESD, specifically no serious or irreversible environmental damage and the conservation of biological diversity and ecological integrity.	Impacts to crustaceans and bivalves arising from the Otway Basin 3D MC MSS will not result in mortality rates beyond the natural range of variation.	The no-effect criteria for crustaceans of 202 dB re 1 µPa PK-PK, was modelled as being detectable at no greater than 512 m from the acoustic source. Given that this threshold represents no observed effects, any crustaceans inhabiting seabed areas at between 512 m and 500 m are considered to exist in areas that are on the outer margins of potential for sub-lethal effects. The area of the AA that lies at between 500 and 520 m is 2.5 km^2 which is 0.0005% of the total AA. The sublethal-effect criteria of 209 - 213 dB re 1 µPa PK-PK for crustaceans was modelled as being detectable at no greater than 157 m from the acoustic source. Given that the seabed is no shallower than 500 m in areas where 3D seismic activities will occur, this level of sub-lethal effects is highly unlikely to occur. Despite the potential vulnerability to seismic emissions of benthic invertebrates due to their limited mobility, the studies that produced the effects threshold criteria adopted here concluded that mortality rates observed during exposure to seismic sound were within the natural range of variation which may be expected to occur due to changes in environmental conditions and anthropogenic stressors. On the basis that any potential sublethal effects to invertebrates in areas shallower than 512 m will be sub-lethal and temporary and that existing literature has found that effect levels at the effect thresholds adopted here potentially fall within the range of existing background variability, the level of consequence is considered minor and the likelihood that minor effects will occur in this area is likely.	Yes
Non-Listed Marine Fauna (Cephalopods Fish, Sharks, Rays)	Principles of ESD, specifically no serious or irreversible environmental damage and the conservation of biological diversity and ecological integrity.	No serious or irreversible damage to a population of any Non-listed marine fauna species as a result of the Otway Basin 3D MC MSS.	**Cephalopods:** The evidence suggests that no serious physiological impacts to individuals or larvae will occur as a result of the Otway Basin 3D MC MSS. The life history traits of cephalopods mean they are well adapted to disturbance and appear to become habituated to acoustic release, displaying other behaviours which indicate rapid recovery. Therefore, no serious or irreversible risks to cephalopod populations are predicted. **Fish:** Consistent with the fisheries management principles, key indicator species have been considered representative of the full fish assemblage which may exist within the OA and relevant distances to thresholds. As described below, no serious or irreversible impacts to key indicator fish populations to the extent that sufficient spawning fish biomass and recruitment of stock may be compromised are predicted. **Sharks and Rays:** No serious or irreversible damage to shark and ray populations are expected.	Yes
EPBC Act Listed marine fauna (White Sharks, Marine Turtles, Marine Mammals, Seabirds)	**Marine Mammals** EPBC Act Part 3 (18A and 20A); EPBC Act Significant Impact Guidelines 1.1; Conservation Management Plan for the Blue Whale; Conservation Management Plan for the Southern Right Whale 2011-2021;	Impacts to EPBC Act Listed marine fauna are limited to minor, short term effects to individuals and ensure biologically important behaviours can continue, within and outside nominated BIAs.	The 16 km buffer zone around the BW BIAs, exclusion of seismic operations within the BW BIAs/buffer during the peak feeding season, the 7 km Extended Shut-down Zone, and the adaptive management controls for BW/PBW have been designed to eliminate any physical or behavioural effects on feeding BW/PBW, hence, to comply with the requirements of the Blue Whale Conservation Management Plan whereby this species can continue to use biologically important areas without injury and that no BW/PBW is displaced from a foraging area.	Yes

Receptor	Relevant External Context	Defined Acceptable Level	Comparison with Predicted Levels of Impact	Acceptable
	Draft National Recovery Plan for the Southern Right Whale (*Eubalaena australis*); Approved Conservation Advice for *Megaptera novaeangliae* (humpback whale); Approved Conservation Advice for *Balaenoptera borealis* (sei whale); Approved Conservation Advice for *Balaenoptera physalus* (fin whale); Recovery Plan for the Australian sea lion (*Neophoca cinerea*); and Conservation Advice *Neophoca cinerea* (Australian sea lion).		The 42 km buffer zone around the SRW Ag BIA, exclusion of seismic operations within the BIA/buffer during the core aggregation months, the 7 km Extended Shut-down Zone, and the adaptive management controls for SRWs have been designed to minimise any physical or behavioural effects SRWs, hence, to comply with the requirements of both the operative SRW Conservation Management Plan and the Draft National Recovery Plan for the SRW whereby anthropogenic threats are demonstrably minimised, and operations adjacent to SRW BIAs do not prevent any SRW from utilising the area or cause injury or disturbance. While the extended 2 km Shut-down Zone for all 'other whales' does not eliminate the risk of cumulative TTS, it provides strong protection from short-term exposure to high levels of underwater noise and both vessel and animal movement will ensure that the likelihood of physiological impacts on other whales remains low. Single-pulse PTS is not predicted for baleen whales (of which some have an EPBC threatened listing) within the limits of the modelling resolution (20 m) and single pulse TTS would only occur if an animal was exposed within 70 m of the source. On this basis, significant injury effects (PTS or TTS) could only occur if a whale went undetected inside the proposed precaution zones or if they remained in the general vicinity of the active source for 24-hours; both vessel and animal movement will ensure that the likelihood of this occurring is very low. On this basis effects will be limited to minor and short-term effects on individuals. Regarding the continuation of biologically important behaviours of 'other whales'; while avoidance behaviours are expected within 12 km of the acoustic source and serve to protect against hearing injury, other EPBC listed whales are probably only present in and around the OA at low densities and the OA does not overlap with habitat identified as biologically important for these species; hence significant effects on biologically important behaviours are not expected.	

Receptor	Relevant External Context	Defined Acceptable Level	Comparison with Predicted Levels of Impact	Acceptable
	Marine Turtles EPBC Act Part 3 (18A and 20A) EPBC Act Significant Impact Guidelines 1.1 Recovery Plan for Marine Turtles in Australia (Commonwealth of Australia 2017)	Impacts to EPBC Act Listed marine fauna are limited to minor, short term effects to individuals and ensure biologically important behaviours can continue, within and outside nominated BIAs.	Industry practice seismic levels associated with PTS and TTS attributable to acoustic emissions in marine turtles is 232 dB_{peak} and 226 dB_{peak}, respectively. Based on the UAM (Welch *et al.,* 2023) these thresholds are expected to be experienced at a maximum distance of 110 m (PTS) and 310 m (TTS). Based on the UAM (Welch *et al.,* 2023), sound pressure levels associated with behavioural response (166 dB re 1µPa) and disturbance (175 dB re 1µPa) were not detected at horizontal distances greater than 4.18 km and 1.37 km, respectively. The OA has not been identified as an area particularly important to marine turtles (i.e. there are no BIAs identified within, or in the vicinity of, the OA) and as such, the presence of marine turtles in the OA during the Otway Basin 3D MC MSS is expected to be low. Marine turtles are therefore unlikely to experience PTS/TTS effects as a result of the Otway Basin 3D MC MSS, which are predicted to be minor and short-term, should they occur. Where they do occur, behavioural effects to marine turtles are predicted to be minor, short-term and affect the small number of individuals that may be transiting the OA. Due to the transient nature of the active acoustic source, whereby the Seismic Vessel will travel at a speed of 4.5 knots, and based on the modelled ranges for behavioural response and disturbance, an individual turtle may respond the acoustic source for approximately one hour and exhibit stronger signs of disturbance for less than 30 minutes. No population level impacts are predicted and the risk to marine turtles is already low.	Yes
	White Sharks EPBC Act Part 3 (18A and 20A) EPBC Act Significant Impact Guidelines 1.1 Recovery Plan for the White Shark	Impacts to EPBC Act Listed marine fauna are limited to minor, short term effects to individuals and ensure biologically important behaviours can continue, within and outside nominated BIAs.	Industry practice seismic levels associated with mortality or mortal injury attributable to seismic emissions on fish with no swim bladders (applicable to whale sharks) is >213 dBpeak. Based on the UAM (Welch *et al.,* 2023) this threshold is expected to be experienced a maximum of 70 m. There is a slight overlap of the OA with the distribution and known distribution BIAs of the white shark, however, this overlap is limited to along the north-eastern to south-eastern boundaries of the OA, limiting the likelihood that white sharks would be utilising the deep waters of the OA. Should white sharks be present within the OA during the survey period, it is expected that these highly mobile individuals would actively avoid the area of acoustic emissions should it be having a negative effect on an individual. Given their limited sensitivity to sound and transient nature of the acoustic emissions, whereby the Seismic Vessel will move at a speed of 4.5 knots, behavioural disturbances to white sharks are predicted to be limited to short-term and one-off disturbances to individuals, should they occur. On this basis, elicitation of potential avoidance behaviours in response to the acoustic source are not expected to displace white sharks from within the BIA or preclude the continuation of biologically important behaviours, noting that the seismic sound emissions have not been identified as a threat to white sharks within the Recovery Plan.	Yes

Receptor	Relevant External Context	Defined Acceptable Level	Comparison with Predicted Levels of Impact	Acceptable
	Seabirds Wildlife Conservation Plan for Seabirds (Commonwealth of Australia 2019)	Impacts to EPBC Act Listed marine fauna are limited to minor, short term effects to individuals and ensure biologically important behaviours can continue, within and outside nominated BIAs.	Birds on the sea surface are unlikely to suffer physiological effects as the Lloyd Mirror effect means that noise levels at the surface are lower than those deeper in the water column. However, studies suggest physiological damage might occur to those seabirds exhibit diving behaviours and which are in extremely close proximity to the acoustic source. Seabirds chase small bait fish as their prey, and it is likely that these small fish would be displaced from the immediate vicinity of the active acoustic source. Seabirds are expected to detect this change in fish distribution and cease any foraging, which would in turn reduce their exposure to any potential physiological effects. Therefore, any impacts to seabirds are predicted to be minor, short term and effect only a small number of individuals. The OA overlaps with the BIAs of 12 species, with these BIAs identified as important foraging areas. Based on the limited effects on seabirds and their prey species, as discussed in the EP, biologically important behaviours are predicted to continue, within and outside the nominated BIAs.	Yes
Marine Protected Areas and Sensitive Areas	EPBC Act South-east Marine Parks Network Management Plan 2013 – 2023 Australian IUCN Reserve Management Principles for Commonwealth Marine Protected Areas	• Meet the Zeehan and Nelson AMP IUCN Category VI (Multiple Use Zone) objective to provide for ecologically sustainable use while conserving ecosystems, habitats and native species. • The Otway Basin 3D MC MSS is undertaken in a manner consistent with the requirements of the South-east Marine Parks Network Management Plan 2013 - 2023 • The ecosystem function and integrity of Commonwealth Marine Areas are maintained.	There are no predicted severe or long-term impacts to individual listed species as a result of the acoustic disturbance to the marine environment and no impacts to ecological populations, habitat or functions are expected to occur. The control measures proposed will serve to protect benthic invertebrates from sub-lethal effects and mortality or mortal injury for site-attached fish (including those commercially targeted) from the Otway Basin 3D MC MSS. Therefore, the Otway Basin 3D MC MSS meets the objectives to: • Provide for ecologically sustainable use while conserving ecosystems, habitats and native species within the Zeehan and Nelson AMP. • Conserve the biodiversity and ecosystem health of the South-east Marine Region • Maintain the ecosystem function and integrity of Commonwealth Marine Areas, including KEFs.	Yes
Commercial Fisheries	The peak industry body representative for commercial fishing, raised concerns regarding the potential effects of the Seismic Survey on commercial catch level. Commercial fisheries data and publications used to inform the impact assessment include: • ABARES Fishery Status Reports 2021 (Patterson *et al.*, 2021); • Commercial fishing catch and effort data for the recent five-year period 2016 – 2020 was obtained from the ABARES, VFA, DNRET and PIRSA which allowed spatial and temporal patterns in fisheries catch and effort distribution to be assessed; and	• No interference with other marine users to an extent greater than is necessary for the exercise of right conferred by the titles granted. • No change to the sustainability status of the fishery; the Otway Basin 3D MC MSS is undertaken in a manner that does not result in serious, irreversible or long-term impacts to key indicator commercial fish populations and to the extent that sufficient spawning fish biomass and recruitment of the stocks may be maintained such that stocks continue to be assessed as sustainable. • There is no increased costs or loss of income for commercial fishing license holders.	The predicted level of interference to commercial fisheries is no greater than is necessary to exercise of right conferred by the titles granted to carry out exploration activities. Based on the detailed evaluation undertaken in **Sections 7.2.2.2.3, 7.2.2.3.2 and 7.2.2.4.1**, the predicted level of impact from acoustic emissions do not exceed the defined acceptable level, given that: • No significant changes in the diversity and abundance of fish species on various reef and non-reef habitats in western Australia have been reported to occur following exposure to seismic emissions. Studies include contemporary investigation of acoustic impacts on commercially important species such as snapper, emperor and groupers, on the North-west Shelf.	Yes

Receptor	Relevant External Context	Defined Acceptable Level	Comparison with Predicted Levels of Impact	Acceptable
	• TGS commissioned the SETFIA to compile an additional review of the level of catch made by Commonwealth and State-managed fisheries within the OA, the proportion of each fisheries' total allowable catch and the annual average catch value that it represents (based upon data from the ten years prior to 2021).		• Despite the potential vulnerability of site attached fish with limited mobility to acoustic emissions, assemblages that have been exposed anthropogenic acoustic disturbances have been reported to exhibit high levels of resilience and quick recovery following exposure. • Commercially important pelagic species such as mackerels do not have a large swim bladder, if present at all, and as such mortality and mortal injury are predicted to occur within a maximum horizontal distance of 80 m from the acoustic source. Species that inhabit the pelagic environment can avoid areas that exceed current conservative industry practise levels. Moreover, as the seismic emission source is moving pelagic fishes would have a period as the source approaches to avoid the area and thus avoid exposure to levels that may cause mortality or mortal injury. • Under a 'worst-case' scenario, the reported mortality rates for fish (cod, saithe, herring, turbot and plaice) larvae and fry due to exposure to acoustic emissions did not approach or exceed natural rates of mortality. • The overall conclusion from the behavioural seismic acoustic exposure experiments was that there was minimal impact on fish behaviour and that any changes that were observed were short term and unlikely to have caused any significant biological or ecological impacts (Woodside, 2007). • Pelagic fish that target zooplankton as prey could be subject to indirect effects associated with changes to the abundance and distribution of zooplankton. These potential flow-on effects to marine food webs are expected to be spatially restricted to within a few kilometres of the Seismic Vessel with baseline conditions resuming relatively quickly after the survey line is complete. The energetic consequences of a small shift in foraging habitat will likely be negligible for pelagic fish. • Where they do occur, reported reductions in catch rates of fish following exposure to acoustic emissions are predicted to be temporary. Based on the available evidence, fish are expected to return to normal behaviour and distributions within days of acoustic exposure. Likewise, catch rates have been observed to return to pre-survey levels following the cessation of acoustic emissions. • Overall, no serious, irreversible or long-term impacts to key indicator commercial fish populations to the extent that sufficient spawning fish biomass and recruitment of stock may be compromised are predicted to occur. On this basis, the sustainability status of the fishery is predicted to be conserved.	

Receptor	Relevant External Context	Defined Acceptable Level	Comparison with Predicted Levels of Impact	Acceptable
			• A Commercial Fisheries Compensation Protocol will be implemented to formally manage claims by commercial fishers for loss of catch, displacement and lost or damaged fishing gear as a consequence of the Otway Basin 3D MC MSS.	
Divers	UK Diving Medical Advisory Committee (DMAC) Safe Diving Distance from Seismic Surveying Operations 2019.	No health impacts to divers or underwater recreational activities as a result of the Otway Basin 3D MC MSS.	No recreational diving is expected to occur within the OA, with recreational diving typically constrained to coastal waters of 30 m or less. Commercial dive operations may occur in the vicinity of the OA around petroleum facilities. All petroleum operators have been consulted with during the preparation of this EP, with this consultation continuing for the life of the EP. TGS will provide look ahead plans to petroleum operators. TGS will conduct a joint risk assessment and planning/mitigation between parties where diving operations will occur within 30 km and will make all parties aware of the Otway Basin 3D MC MSS where diving and seismic activities will occur within 45 km of each other. Should new diving activities be identified, the adopted control measures regarding notification of survey commencement to diving operators and the need to conduct joint risk assessment where diving and seismic activities occur within 30 km of each other, ensure that no health impacts to divers will occur as a result of the Otway Basin 3D MC MSS.	Yes

Acceptability Statement
Impacts and risks classified as ‘Type B’ or above are considered acceptable if the requirements in **Table 51** can be demonstrated and it can be determined that the predicted levels of impact and/or residual risk are at or below pre-defined Acceptable Levels for that impact or risk, including those described in **Table 52**. Based on the above evaluation, the potential impacts from acoustic disturbance to the marine environment meets the requirements of the risk acceptability criteria. The control measures that will be implemented throughout the Otway Basin 3D MC MSS have been developed in accordance with these criteria and are considered appropriate to manage the impacts of acoustic disturbance to the marine environment on all receptors, including the associated disruption and interference with other marine users to an **Acceptable Level.**

7.2.7 Environmental Performance

Table 87 Environmental Performance Outcomes, Standards and Measurement Criteria for Acoustic Disturbance to the Marine Environment

Number	Environmental Performance Outcome	Environmental Performance Standard
EPO 4	Seismic acquisition is undertaken in a manner that limits impacts from underwater noise to individual listed threatened, listed migratory or listed marine fauna protected under the EPBC Act to minor, short term effects and do not preclude the continuation of biologically important behaviours.	**EPS 53** to- **EPS 88**, **EPS 111** to **EPS 162**
EPO 5	Seismic acquisition is undertaken in a manner that prevents serious or irreversible damage to a population of marine fauna species not listed as threatened or migratory under the EPBC Act from underwater noise.	**EPS 53** to **EPS 88**, **EPS 111**to **EPS 137**, **EPS 143** to **EPS 144**, **EPS 160**
EPO 6	Seismic acquisition is undertaken in a manner such that any pygmy blue whales may continue to utilise the area without injury and are not displaced from a foraging area.	**EPS 53** to **EPS 88**, **EPS 111**to **EPS 125**, **EPS 128** to **EPS 130**, **EPS 132** to **EPS 133**, **EPS 136** to **EPS 139**, **EPS 143** to **EPS 152**, **EPS 161** to **EPS 162**
EPO 7	Seismic acquisition is undertaken in a manner such that any southern right whale may continue to utilise the area without injury or significant behavioural impacts.	**EPS 53** to **EPS 88**, **EPS 111**to **EPS 127**, **EPS 130**, **EPS 132** to **EPS 133**, **EPS 135** to **EPS 137**, **EPS 140** to **EPS 144**, **EPS 153** to **EPS 159**
EPO 8	Seismic acquisition is undertaken in a manner that preserves the sustainability status of the relevant fishery, as any impacts to stock, spawning or fishing activities will be minor, recoverable and short-term.	**EPS** 53 to **EPS** 54, **EPS** 85 to **EPS** 93, **EPS** 96 to **EPS** 108, **EPS** 116, **EPS** 131
EPO 9	Seismic acquisition is undertaken in a manner that prevents any increased cost encumbrance or loss of income to commercial fishing license holders.	**EPS** 53 to **EPS** 54, **EPS** 85 to **EPS** 93, **EPS** 96 to **EPS** 108, **EPS** 116**, EPS** 131
EPO 10	Seismic acquisition is undertaken in a manner that does not compromise the objectives of relevant recovery plans or wildlife conservation plans/advice that are in force for a marine fauna species.	**EPS 53** to **EPS 88**, **EPS 111** to **EPS 132**, **EPS 137** to **EPS 162**
EPO 11	Seismic acquisition is undertaken in a manner that does not compromise the ecosystem function or integrity of Commonwealth marine areas.	**EPS 53** to **EPS 88**, **EPS 111**to **EPS 132**, **EPS 137**, **EPS 143** to **EPS 162**
EPO 12	Seismic acquisition is undertaken in a manner that does not compromise the ecosystem function or integrity of AMPs or conservation status of native species within the AMPs.	**EPS 53** to **EPS 88**, **EPS 111** to **EPS 132**, **EPS 137** to **EPS 162**
EPO 13	Seismic acquisition is undertaken in a manner that prevents widespread (>100s of m from the acoustic source) and long term (>1 week to recover) impacts to plankton communities.	**EPS** 53 to **EPS** 54, **EPS** 85 to **EPS** 88, **EPS** 96
EPO 14	Seismic acquisition is undertaken in a manner that prevents any detectable impacts to habitat forming primary producers, such as coral.	**EPS** 53 to **EPS** 54, **EPS** 85 to **EPS** 88, **EPS** 96
EPO 15	Seismic acquisition is undertaken in a manner that prevents lethal injury or mortality to crustaceans and bivalves at rates beyond the natural range of variation.	**EPS** 53 to **EPS** 54, **EPS** 85 to **EPS** 88, **EPS** 96
EPO 16	Seismic acquisition is undertaken in a manner that prevents any health impacts to divers or underwater recreational activities due to underwater seismic emissions.	**EPS** 53 to **EPS** 54, **EPS** 85 to **EPS** 93, **EPS** 96, **EPS** 109 to **EPS** 110
EPO 17	Seismic acquisition is undertaken in a manner such that it does not interfere with other marine users to a greater extent than is necessary for the exercise of right conferred by the titles granted to carry out exploration activities.	**EPS** 53 to **EPS** 54, **EPS** 85 to **EPS** 96
EPO 18	Seismic acquisition is undertaken in a manner that prevents any damage to UXOs or defence activities	**EPS** 53 to **EPS** 54, **EPS** 85 to **EPS** 88, **EPS** 163 to **EPS** 164

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
The Otway Basin 3D MC MSS will be undertaken in accordance with the approved EP.	**EPS 53**: The Otway Basin 3D MC MSS may only commence following acceptance of the EP by NOPSEMA.	Pre-mobilisation audit and inspection are completed prior to operations and confirm an accepted EP has been obtained. Audit records verify compliance with the requirements of the EP.	TGS VOM EA
	EPS 54: The Otway Basin 3D MC MSS will be undertaken in accordance with the accepted EP.	Bridge logs verify compliance with the requirements of the EP. Audit records verify compliance with the requirements of the EP.	TGS VOM VOC EA Vessel Master SEA
Adherence to Policy Statement 2.1 requirements, through the implementation of the following control measures with respect to all whales (baleen and toothed), throughout the entire OA for the duration of the Otway Basin 3D MC MSS: • Observation Zone[AC]: 5+ km horizontal radius from the acoustic source; • Shut-down Zone[AC]: 2 km horizontal radius from the acoustic source; • Crew training: Crew are trained in the basic requirements of Policy Statement 2.1 prior to the survey commencement • Pre-start-up Visual Observations (daylight hours): 30 minutes prior to the commencement of Soft-start Procedure; • Soft-start Procedure: Commences only when no whales have been sighted within the relevant Shut-down Zone over a 30 minute Pre-start up Visual Observation period; • Start-up Delay Procedures: Will be implemented if a whale enters the Shut-down Zone during the Soft-start Procedures; • Stop Work Procedures: Will be implemented whenever a whale is detected in the relevant Shut-down Zone; • Night-time and Low Visibility Procedures: Will be implemented throughout periods of low visibility, including night-time, under rough seas or fog; • Compliance and sighting reports.	**EPS 55**: Operations will comply with Policy Statement 2.1. Part A requirements at all times, to mitigate potential impacts to whales.	Compliance and sighting reports as per Policy Statement 2.1 Part A.4 verify the implementation of these procedures.	Vessel Master SEA CSR MFO
	EPS 56: During daylight hours at least one MFO will be on duty at all times from the Seismic Vessel and one MFO will be on duty at all times from the Attending Support Vessel to undertake continuous visual observations for marine mammals[AC.]	Compliance and sighting reports as per Policy Statement 2.1 Part A.4 verify the implementation of these procedures.	Vessel Master SEA CSR MFO
	EPS 57: MFOs will implement a 5+ km Observation Zone[AC] from the acoustic source.	Compliance and sighting reports as per Policy Statement 2.1 Part A.4 verify the implementation of these procedures.	Vessel Master SEA CSR MFO
	EPS 58: During daylight hours, Pre Start-up Visual Observations for the presence of whales within the 5+ km Observation Zone will be undertaken for at least 30 minutes before the commencement of the Soft Start Procedure	Compliance and sighting reports as per Policy Statement 2.1 Part A.4 verify the implementation of these procedures.	Vessel Master SEA CSR MFO
	EPS 59: If no whales have been sighted within the relevant Shut-down Zones, Soft-start Procedures will commence over a 30-minute period;	Compliance and sighting reports as per Policy Statement 2.1 Part A.4 verify the implementation of these procedures.	Vessel Master SEA CSR MFO
	EPS 60: A 2 km Shut-down Zone[AC] for all whales will be implemented throughout the entire OA at all times. On this basis a Low Power Zone is unnecessary	Compliance and sighting reports as per Policy Statement 2.1 Part A.4 verify the implementation of these procedures.	Vessel Master SEA CSR MFO
	EPS 61: A start-up Delay will occur if a whale enters or is detected in the relevant Shut-down Zone during Soft-start Procedures. Whale presence within the Shut-down Zone will trigger an immediate and complete shut-down, and Soft-start Procedures may only resume after the whale has been observed to move outside the relevant Shut-down Zone, or when 30 minutes have lapsed since the last whale sighting	Compliance and sighting reports as per Policy Statement 2.1 Part A.4 verify the implementation of these procedures.	Vessel Master SEA CSR MFO
	EPS 62: If a whale is detected within any nominated observation zone during the Otway Basin 3D MC MSS, an additional MFO will be stationed on the bridge of the vessel from which the detection was made to assist with observations. The only permissible exception to this is when the off-duty MFO is on a meal or toilet break or is standing-down having reached maximum shift duration for that particular working day. In these instances, a trained crew member will assist with marine mammal observation	Compliance and sighting reports as per Policy Statement 2.1 Part A.4 verify the implementation of these procedures.	Vessel Master SEA CSR MFO

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
	EPS 63: Stop Work Procedures will be implemented for the entire duration in which operations are underway as follows: the acoustic source will shut-down whenever a whale is detected in the relevant Shut-down Zone. Soft-start Procedures may only resume after the whale has been observed to move outside the relevant Shut-down Zone, or when 30 minutes has lapsed snice the last whale sighting	Compliance and sighting reports as per Policy Statement 2.1 Part A.4 verify the implementation of these procedures.	Vessel Master SEA CSR MFO
	EPS 64: Low visibility or night-time operations may occur provided that there have not been three or more whale instigated power-down or shut-down situations during the preceding 24-hour period	Compliance and sighting reports as per Policy Statement 2.1 Part A.4 verify the implementation of these procedures.	Vessel Master SEA CSR MFO
	EPS 65: When species identification is uncertain, a precautionary approach will be taken, and the most conservative option in accordance with the additional management procedures for BW/PBW or SRWs will be followed until identification is otherwise confirmed	Compliance and sighting reports as per Policy Statement 2.1 Part A.4 verify the implementation of these procedures.	Vessel Master SEA CSR MFO
Policy Statement 2.1: Precaution Zones: • Observation Zone[AC]: 5+ km horizontal radius from the acoustic source; • Shut-down Zone[AC]: 2 km horizontal radius from the acoustic source for 'other whales'; • An Extended Observation Zone for BW/PBW and SRW to a minimum of 7 km. • An Extended 7 km Shut-down Zone[AC] for BW/PBW and SRW; and • Shut-down at any distance for a SRW mother-calf pair.	**EPS 66**: The following Precaution Zones will be implemented throughout the duration of the Otway Basin 3D MC MSS: • Observation Zone – 5+ km horizontal radius from the acoustic source using the Seismic Vessel as the observation platform; • Extended Observation Zone for BW/PBW and SRW such that vessel based MFOs observe for BW/PBWs and SRWs as far as practicable, and to a minimum of 7 km during daylight hours. • Extended 7 km Shut-down Zone[AC] for BW/PBW and SRWs; • Extended 2 km Shut-down Zone[AC] for all 'other whales'.	MFO daily and weekly logs confirm the Precaution Zones were implemented.	SEA MFOs Party Chief CSR
	EPS 67: The acoustic source will be shut-down at any distance for a SRW mother-calf pair detection.	MFO daily and weekly logs confirm the Precaution Zones were implemented and shut downs occurred in the presence of a SRW mother-calf pair.	SEA MFOs Party Chief CSR
	EPS 68: MFOs and PAM operators onboard will have the primary responsibility for whale observation and compliance of the Precautionary Zones.	MFO and PAM daily and weekly logs confirm the Precaution Zones were implemented.	SEA MFOs CSR
Policy Statement 2.1: A.2 – Crew training (General crew).	**EPS 69**: All vessel crew will be trained to understand the basic requirements of Policy Statement 2.1 and the specific Precaution Zones that will be implemented as part of the Otway Basin 3D MC MSS.	Induction records outline the content of vessel inductions and crew present. A copy of these records will be kept onboard the Seismic Vessel and the CSR will also have a copy.	CSR SEA Vessel crew
	EPS 70: Vessel crews, MFOs and PAM Operators will be briefed on the EP controls and EP reporting requirements.	Induction records outline the content of vessel inductions and crew present. A copy of these records will be kept onboard the Seismic Vessel and the CSR will also have a copy.	CSR SEA Vessel crew
	EPS 71: Trained crew will act in a supporting role to the MFO by immediately reporting any opportunistic marine mammal sighting (from either the Seismic Vessel or any of the support vessels) to the on-duty MFO and assisting with MM observations as requested by the on-duty MFO.	Compliance and sighting reports as per Policy Statement 2.1 Part A.4 verify the implementation of this procedure. Bridge logs record opportunistic sightings by trained crew and confirms they were reported to the MFO. MFO daily and weekly logs record opportunistic sightings by trained crew.	CSR SEA Vessel crew

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
	EPS 72: MFOs and PAM Operators will be inducted in their responsibilities regarding environmental matters (including Policy Statement 2.1 and all additional management procedures specific to the Otway Basin 3D MC MSS), whale identification, and the environmental legal obligations for companies operating in Australian waters.	Induction records outline the content of MFOs and PAM Operator inductions and personnel present.	CSR SEA MFO PAM Operators
	EPS 73: Reference material will be available onboard all vessels, with available materials Policy Statement 2.1, the Department's whale and dolphin sighting report form, and the APPEA CD Guide Search Australian Whales and Dolphins, and a copy of this EP.	Audit/inspection records verify the presence of reference materials on board the vessel.	CSR SEA
	EPS 74: Appropriate visual aids such as binoculars will be available on board the vessel to aid in the identification and reporting of any whales sighted.	Audit/inspection records verify the presence of suitable visual ais on board the vessel.	CSR SEA
Policy Statement 2.1: A.3.1 – Pre-start-up visual observations procedures. The 5+ km Observation Zone^{AC} will be monitored for the presence of whales for at least 30 minutes before the commencement of a Soft-start Procedures.	**EPS 75**: During daylight hours, visual observations for the presence of whales will be undertaken by the on-duty MFO onboard the Seismic Vessel in the 5+ km Observation Zone^{AC} for at least 30 minutes before the commencement of Soft-start Procedures.	Compliance and sighting reports as per Policy Statement 2.1 Part A.4 verify the implementation of this procedure. MFO daily and weekly logs confirm Pre-start-up procedures were implemented.	SEA MFOs Vessel Master CSR
Policy Statement 2.1: A.3.2 – Soft-start procedures. Limits on when soft start procedures can commence will be applied for the duration of the survey as follows: • If no acquisition has occurred in the preceding 24 hours, soft starts may only commence in daylight hours and when conditions allow visual inspection of the 5+ km Observation Zone^{AC}; • If acquisition has occurred within the preceding 24 hours and no whale initiated shut-downs have been made during this period, then soft starts may commence at night or during periods of low visibility providing they occur outside of the BW BIAs/buffer and the SRW Ag BIA/buffer.	**EPS 76**: Soft start procedures throughout the OA can only proceed under the following circumstances: • If no acquisition has occurred in the preceding 24 hours, soft starts may only commence in daylight hours and when conditions allow visual inspection of the 5+ km Observation Zone^{AC}; • If acquisition has occurred within the preceding 24 hours and no whale initiated shut-downs have been made during this period, then soft starts may commence at night or during periods of low visibility providing they occur outside of the BW BIAs/buffer and the SRW Ag BIA/buffer.	Compliance and sighting reports as per Policy Statement 2.1 Part A.4 verify the implementation of this procedure. MFO daily and weekly logs confirm soft-start procedures were implemented.	SEA MFOs Vessel Master CSR
Policy Statement 2.1: A.3.3 – Start-up delay procedures (if a whale is detected in any relevant Shut-down Zone during pre-start observations or during the soft start procedure).	**EPS 77**: If a whale is sighted within any Observation Zone during Soft-start Procedures, an additional MFO will be brought to the bridge of the vessel from which the detection was made to assist with observations. The only permissible exception to this is when the off-duty MFO is on a meal or toilet break or is standing down having reached maximum shift duration for that particular working day. In these instances, a trained crew member will assist with marine mammal observations.	Compliance and sighting reports as per Policy Statement 2.1 Part A.4 verify the implementation of this procedure. MFO daily and weekly logs confirm start-up delay procedures were implemented.	SEA MFOs Vessel Master CSR
	EPS 78: If any 'other whale' is sighted within or about to enter the 2 km Extended Shut-down Zone^{AC}, the acoustic source will shut-down completely. A Soft-start Procedure will resume only after the whale has been observed to move outside the 2 km Extended Shut-down Zone^{AC}, or when 30 minutes has lapsed since the whale was last sighted.	Compliance and sighting reports as per Policy Statement 2.1 Part A.4 verify the implementation of this procedure. Bridge logs. MFO daily and weekly logs confirm start-up delay procedures were implemented.	SEA MFOs Vessel Master CSR

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
	EPS 79: If a BW/PBW or SRW is sighted within or about to enter the 7 km Extended Shut-down Zone during soft-start procedures, the acoustic source will shut-down immediately and soft start procedures may only resume once the BW/PBW or SRW is observed to move outside this Shut-down Zone or when 30 minutes have lapsed since the last BW/PBW or SRW sighting.	Compliance and sighting reports as per Policy Statement 2.1 Part A.4 verify the implementation of this procedure. Bridge logs. MFO daily and weekly logs confirm start-up delay procedures were implemented.	SEA MFOs Vessel Master CSR
Policy Statement 2.1: A.3.5 – Stop Work Procedures. Stop work procedures will be implemented when: • Any 'other whale' enters or is detected in the Extended 2 km Shut-down Zone[AC;] • A BW/PBW enters or is detected in the Extended 7 km Shut-down Zone[AC]; • A SRW enters or is detected in the Extended 7 km Shut-down Zone[AC]; or • MFOs onboard the Seismic Vessel or the attending support vessel detect a SRW mother-calf pair at any distance.	**EPS 80**: If a whale is detected within any Observation Zone during daylight hours, an additional MFO will be stationed on the bridge of the vessel from which the detection was made to assist with observations. The only permissible exception to this is when the off-duty MFO is on a meal or toilet break or is standing-down having reached maximum shift duration for that particular working day. In these instances, a trained crew member will assist with marine mammal observations.	Compliance and sighting reports as per Policy Statement 2.1 Part A.4 verify the implementation of this procedure. MFO daily and weekly logs confirm stop work delay procedures were implemented.	MFOs SEA CSR
	EPS 81: Policy Statement 2.1: A.3.5 – Once full power operations are underway, the following Stop Work Procedures and additional controls will be applied: • If a BW/PBW is detected within the 7 km Extended Shut-down Zone[AC] the acoustic source will be immediately shut-down and the seismic vessel will relocate to another area at least 32 km away from the last PBW sighting before commencing Pre Start-up Visual Observations and Soft Start Procedures. If relocation of the seismic vessel is not possible, then acquisition will cease and will not recommence until 24 hours have elapsed and no BW/PBW has been detected in the 7 km Extended Shut-down Zone. • If a SRW is detected within the 7 km Extended Shut-down Zone[AC] the acoustic source will be immediately shut-down and the seismic vessel will relocate to another area at least 11 km away from the last SRW (unaccompanied) sighting before commencing Pre Start-up Visual Observations and Soft Start Procedures. Note that this distance increases to 42 km if a calf is present. If relocation of the seismic vessel is not possible, then acquisition will cease and will not recommence until 24 hours have elapsed and no SRW has been detected in the 7 km Extended Shut-down Zone. • If an 'other whale' is detected within/about to enter the 2 km Extended Shut-down Zone[AC], the acoustic source will be shut-down immediately. • If a SRW mother-calf pair is observed from the Seismic Vessel or Attending Support Vessel at any distance during the Otway Basin 3D MC MSS, the acoustic source will be immediately shut-down and the Seismic Vessel will relocate to another area at least 42 km away, and outside of the SRW Ag BIA/buffer, before commencing Pre Start-up Visual Observations and Soft Start Procedures.	Compliance and sighting reports as per Policy Statement 2.1 Part A.4 verify the implementation of this procedure. MFOs daily and weekly logs confirm stop work delay procedures were implemented.	MFOs SEA CSR Vessel Master

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
	EPS 82: Power-up of the acoustic source during the resumption of operations will only occur as follows: • For 'other whales' – when the individual whale/s have been observed to more outside the relevant Shut-down Zone, or when 30 minutes has lapsed since the last sighting. Power-up will follow the Soft-start Procedure. • For BW/PBW – once the seismic vessel has relocated to another area at least 32 km away from the last PBW sighting and Pre Start-up Visual Observations and Soft Start Procedures have occurred. Noting that if relocation of the seismic vessel is not possible, then acquisition will cease and will not recommence until 24 hours have elapsed and no BW/PBW has been detected in the 7 km Extended Shut-down Zone. • For SRW - once the seismic vessel has relocated to another area at least 11 km away (for unaccompanied whales) or 42 km away (for mother-calf pairs) from the last SRW sighting and Pre Start-up Visual Observations and Soft Start Procedures have occurred. Noting that if relocation of the seismic vessel is not possible, then acquisition will cease and will not recommence until 24 hours have elapsed and no BW/PBW has been detected in the 7 km Extended Shut-down Zone.	Compliance and sighting reports as per Policy Statement 2.1 Part A.4 verify the implementation of this procedure. MFOs daily and weekly logs confirm stop work delay procedures were implemented.	MFOs SEA CSR Vessel Master
Policy Statement 2.1: A.3.6 – Night-time and low visibility procedures. During these periods, operations may proceed provided there have not been three or more whale instigated shut-downs during the preceding 24-hour period. Commencement of soft-start procedures at night or during periods of low visibility will be limited to circumstances when: • Acquisition has occurred within the preceding 24 hours and no whale initiated shut-downs have been made during this period; and • may only occur outside of the BW BIAs/buffer and the SRW Ag BIA/buffer[AC]. • Additional criteria relating to BW/PBW or SRW shut-downs must also be satisfied before night time and low visibility operations can occur as described later in this table.	**EPS 83**: Low visibility or night-time operations may occur provided: • there have not been three or more whale instigated shut-downs during the preceding 24-hour period. In addition, commencement of soft-start procedures at night or during periods of low visibility will be limited to circumstances when: • Acquisition has occurred within the preceding 24 hours and no whale initiated shut-downs have been made during this period; and • may only occur outside of the BW BIAs/buffer and the SRW Ag BIA/buffer[AC].	Compliance and sighting reports as per Policy Statement 2.1 Part A.4 verify the implementation of this procedure. MFO and PAM daily and weekly logs confirm night-time and low visibility procedures were implemented.	MFOs SEA CSR Vessel Master
Policy Statement 2.1: A.4 – Compliance and Sighting Reports. All cetacean sightings will be recorded in the 'Cetacean Sightings Application' software.	**EPS 84**: Whale sightings will be reported in accordance with Policy Statement 2.1 Part A.4 Compliance and Sighting Reports requirements, including submission of a report to the DoEE within two months of the survey completion.	Compliance and sighting reports as per Policy Statement 2.1 Part A.4. Whale Observation Report confirms compliance.	MFOs SEA CSR
The minimum source size to acquire the survey data and meet the geophysical objectives of the Otway Basin 3D MC MSS has been selected. The acoustic source size used will not exceed that which has been modelled (3,480 in^3) and for which the predicted impacts and risks have been assessed. If the source used for the Otway Basin 3D MC MSS differs to that modelled in the EP, additional modelling will be undertaken.	**EPS 85**: The acoustic source will have a maximum source output no greater than 3,000 in^3, with a maximum zero to peak SPL of 256.3 dB re 1 µPa @ 1 m. Care will be taken to ensure spare acoustic sources are not discharged as part of the active source array.	MFOs will record source volumes as part of their daily observations each swing. MFOs daily and weekly logs confirm compliance.	Party Chief Vessel Master Survey Environmental Advisor MFOs TGS QC and HSE Representative
	EPS 86: If the source used for Otway Basin 3D MC MSS differs to that modelled within Welch *et al.* (2023), additional modelling will be undertaken, and the control measures and EPSs reviewed as appropriate to confirm they continue to manage impacts to ALARP and Acceptable Levels. Changes will be documented as per the Management of Change requirements.	MFOs will record source volumes as part of their daily observations each swing. MFOs daily and weekly logs confirm compliance. Documentation of modelling report and review of control measures/EPSs as per the Management of Change requirements.	EA

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
The acoustic source will only be deployed and retrieved within the bounds of the OA.	**EPS 87:** The acoustic source will be retrieved and brought onboard the Seismic Vessel when not required, and will only be permitted to be in the water when in the bounds of the OA. The acoustic source will not be deployed or retrieved when outside the boundaries of the OA.	Compliance and sighting reports as per Policy Statement 2.1 Part A.4 show no breach in operations. Bridge logs. MFOs daily and weekly logs confirm compliance.	Vessel Master SEA MFOs CSR Seismic Operations Technicians
	EPS 88: Shape files will be loaded onto the survey vessels' navigation system outlining the areas within which the acoustic source may be activated, against the boundary extents of the OA and AA.	Exclusion polygons on survey vessel's navigation system.	Vessel Master SEA CSR Party Chief
A communications protocol will be in place between the survey vessels and other relevant persons (e.g. commercial fishers known to utilise the OA, oil and gas operators), to actively manage concurrent activities.	**EPS 89**: Pre-survey consultation with relevant persons, confirming the Otway Basin 3D MC MSS will proceed, no less than four weeks before operations commence.	Documentation of consultation and consultation log demonstrate compliance.	EA TGS VOM
	EPS 90: Onshore personnel (EA) will communicate any updates determined through the continuing consultation process to the Vessel Master, where they have the potential to impact the Otway Basin 3D MC MSS and/or relevant persons.	Documentation of consultation and consultation log demonstrate compliance. Forms part of continuing consultation strategy.	EA Vessel Master
	EPS 91: Relevant persons will be notified following the conclusion of the survey as per the following Post-Activity Notifications: • All relevant persons – relevant time post completion; • AMSA – relevant time post completion; • NOPSEMA – 10 days post completion advising the completion of the Seismic Survey; and • NOPSEMA – As soon as practicable advising that all of the activities and obligations covered under the EP have been completed.	Documentation of consultation and consultation log demonstrate compliance.	EA TGS VOM
	EPS 92: A 48-hour 'look-ahead plan' will be provided to relevant persons (who register for the service) identified throughout the relevant persons consultation process, detailing the survey activities over the next 48 hours. The 48-hour look-ahead plans will be updated and issued every 24 hours and distributed to relevant persons via email.	Documentation of consultation, consultation log and issuing of weekly and 48-hour look-ahead plans demonstrate compliance. Forms part of continuing consultation strategy.	TGS VOM EA CSR Vessel Master
Publication of a Notice to Mariners of survey presence and towed array, no less than four weeks before operations commence.	**EPS 93**: A Notice to Mariners will be published and distributed by the AHO under the Navigation Act 2012, informing other marine users of the Seismic Survey, no less than four weeks before operations commence.	Record of Notice to Mariners.	EA TGS VOM
Where the potential for concurrent MSSs to occur is identified, TGS will engage with proponents prior to commencing the Otway Basin 3D MC MSS and develop a SIMOPS plan. SIMOPS planning will include the implementation of a 40 km spatial separation between the acoustic source and any other operating acoustic source in the Otway Basin area.	**EPS 94**: The NOPSEMA database of activity status and summaries has been searched to identify the potential for temporal and spatial overlap with other MSSs in the Otway Basin, in the development of this EP and will be searched immediately prior to the survey commencing for completeness.	Search of the NOPSEMA activity status and summaries website, looking in particular for EP submissions or decisions in the surrounding areas to the OA is completed and documented within the EP. This will be completed, again, immediately prior the survey and documented within SIMOPS plan.	EA TGS VOM
	EPS 95: A SIMOPS plan is developed and implemented where concurrent MSSs are identified to occur.	SIMOPS Plan documents the following: • Communications protocols • Work programming • Hazard management • Emergency Response Bridge logs confirm implementation and compliance.	EA Vessel Master SEA CSR
	EPS 96: TGS will maintain at least 40 km separation distance with any concurrent MSS at all times to avoid cumulative impacts to marine fauna.	Vessel track records as well as AIS track records demonstrate compliance. Communication records between the title holders and survey vessels.	Vessel Master SEA CSR

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
Compensation to fishers and vessel crews (i.e., the claimant) is demonstrated to have occurred for the following circumstances: • Interaction resulting in loss or damage to fishing equipment; • A temporary loss of fish landed catch due to damaged or lost fishing equipment; • Where displacement from fishing grounds results in additional costs incurred due to relocating; or • A temporary reduction in fish landed catch due to the effects of acoustic emissions or displacement from fishing grounds. Claims received from fishers in any circumstances other than those outlined above will not be assessed. Claims will be considered provided the interaction/displacement/loss of catch took place in the Adjustment Area (plus any additional area of avoidance requested around the survey vessels and towed equipment.) where the Otway Basin 3D MC MSS took place, and within the project active time frame only.	**EPS 97**: A Commercial Fisheries Compensation Protocol is in place for the Otway Basin 3D MC MSS.	Documentation of consultation demonstrates Fisheries Compensation Protocol for the Otway Basin 3D MC MSS is in place for the Seismic Survey	TGS VOM EA
	EPS 98: Pre-survey consultation with commercial fishers known to utilise the OA, notifying them in writing of the Commercial Fisheries Compensation Protocol in place for the Otway Basin 3D MC MSS, no less than 28 days before operations commence. Notification will be via SETFIA, TSIC, SIV, or AFMA (as relevant to each fishery) and will be provided in the form of a map, showing the OA and associated Adjustment Area, plus digital files in formats such as shapefiles and a copy of the Protocol in full.	Documentation of consultation demonstrates the Commercial Fisheries Compensation Protocol is in place for the Otway Basin 3D MC MSS and was provided to commercial fishers known to utilise the OA no less than 28 days before operations commence. Information provided is demonstrated to include a copy of the Protocol in full, a map showing the OA and Adjustment Area, plus digital files in formats such as shapefiles.	TGS VOM EA
	EPS 99: Eligible Commercial Fishes have been provided application forms and contact point relevant to commercial fishers relating to lodging a claim or notification regarding loss of catch, displacement, or fishing gear loss of damage.	Documentation of consultation demonstrates Attachment A of the Commercial Fisheries Compensation Protocol was attached to the pre-survey consultation with commercial fishers known to utilise the OA, and that contact point has been provided to commercial fishers.	TGS VOM EA
	EPS 100: Subject to a claim being lodged, a suitably experienced/qualified independent person/organisation will be engaged as the assessor of the claim, in consultation with the claimant. Suitably experienced and qualified is defined as a person or organisation with proven demonstrated experience in data analysis and data auditing processes and procedures within the industry.	Documentation of consultation with claimant around engagement of independent assessor, appropriate experience/qualifications of independent assessor, and agreements in place between TGS and independent assessor to engage their services for assessing the claim.	TGS VOM EA
	EPS 101: TGS will provide the assessor with a letter of instruction/project brief, which is to also be provided to the claimant as part of the assessment report.	Documentation of communications with assessor and claimant including provision of letter of instruction/project brief.	TGS VOM EA
	EPS 102: All compensation claims made by commercial fishing license holders or vessel crews for equipment damage/loss, displacement and loss of catch will be assessed for merit in accordance with the processes outlined in the Commercial Fisheries Compensation, within 30 days of receiving the claim.	Records demonstrate that claims made by commercial fishery license holders and vessel crew were assessed in accordance with the processes outlined in the Commercial Fisheries Compensation Protocol.	TGS VOM EA
	EPS 103: Where a commercial fishing licence holder has been involved in an interaction leading to loss or damage to the licence holder's equipment or displacement from usual fishing grounds, all interactions between the commercial fishing licence holder and the survey vessels will be recorded by the MSS operator. Details to be recorded should include, but not be limited to: the time, date and location coordinates of where the gear interaction occurred or the fishing was aborted and where it recommended, the name of the vessel, the licence holder number on the fishing gear, and any details of communications between the commercial fishing licence holder and the vessel/s.	Records demonstrate documentation of interactions with commercial fishing licence holder leading to loss or damage of the licence holder's equipment or displacement from usual fishing grounds.	Vessel Master
	EPS 104: Where possible and safe to do so, the Vessel Master shall make attempts to recover any fishing equipment. Photos will be provided to TGS by the Vessel Master.	Records demonstrate attempts to retrieved fishing equipment and photos of retrieved equipment.	Vessel Master.
	EPS 105: The independent assessor is to provide TGS with an assessment report which is to include the following information: - A copy of the letter of instruction/project brief; - Confirmation (or otherwise) that the information provided in the claim is sufficient to conduct a meaningful assessment; - A summary of the claim details (survey, applicant, vessel, month/s);	Records demonstrate receipt of assessment report and consultation with claimant.	TGS VOM EA

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
	- For a loss of catch claim, monthly CPUE assessments as outlined in the Commercial Fisheries Compensation Protocol, including an estimation of any loss of catch and its market price; and - Any other information, comments, or views relevant to the assessment that the assessor may wish to include. Upon receiving and considering the assessment report, TGS will provide a copy of the report to the claimant and offer to meet with the claimant to discuss/address the claim.		
	EPS 106: All claimants will be notified of the outcome of the claim (or request clarification/additional information from the claimant) as soon as practicable and within 30 days after receiving the application, in accordance with the Commercial Fisheries Compensation Protocol.	Records demonstrate claimants were notified of the outcome of the claim or request for clarification/additional information, within 30 days of receiving the claim, in accordance with the Commercial Fisheries Compensation Protocol.	TGS VOM EA
	EPS 107: All claimants considered to have a claim of merit will receive compensation, in accordance with the Commercial Fisheries Compensation Protocol within 60 days of the claim determination. Claimants will be contacted via the email addressed provided within the claim application, unless requested otherwise. Compensation value paid will calculated based on the measures provided in the Commercial Fisheries Compensation Protocol.	Records demonstrate all claimants considered to have a claim of merit received compensation in accordance with the Commercial Fisheries Compensation Protocol, within 60 days of the claim determination.	TGS VOM EA
	EPS 108: In the event that a claimant disagrees with a claim assessment outcome, and an agreement cannot be reached between TGS and the claimant, the claimant may, within 30 days, opt to request that a suitably experienced/qualified independent third-party is engaged to review and determine the outcome of the claim. The appointment of the independent third party will be agreed mutually between TGS and the claimant. The dispute will be resolved within 60 days of dispute received by TGS, with the costs of engaging the independent third-party assessor covered by TGS.	Records demonstrate that a claimant's dispute has been assessed by a suitable experience/qualified independent third-party, where requested, and that costs of engaging the independent third-party assessor have been covered by TGS. Records document outcome of the independent third-party assessor's assessment and that the dispute has been resolved within 60 days of receipt of the dispute.	TGS VOM EA
Notification to recreational and commercial divers that are undertaking diving activities within 45 km of the acoustic source.	**EPS 109**: A Notification of MSS commencement will be provided to diving operators undertaking any diving activities within 45 km of the acoustic source, no less than four weeks before operations commence.	Documentation of consultation, consultation log demonstrates compliance.	EA SEA CSR
A joint risk assessment will be conducted with recreational and commercial divers where their respective diving activities may occur within 30 km of the acoustic source.	**EPS 110**: Where diving and seismic activities occur within 30 km of each other, a joint risk assessment between TGS and the proponent undertaking diving activities will be conducted prior to either operator commencing activity.	Documentation of consultation, consultation log demonstrates compliance. Records confirm a joint risk assessment has been developed, where diving and seismic activities occur within 30 km of each other. Bridge logs confirm implementation and compliance	EA Vessel Master SEA CSR
A 100 m precautionary Shut-down Zone from the operating source will be applied to marine turtles. The acoustic source will be shut-down, or start-up will be delayed for 15 minutes if a marine turtle is observed within the 100 m Shut-down Zone. Operation of the acoustic source using soft-starts may only resume when the turtle has been observed to move outside the 100 m Shut-down Zone, or when 15 minutes have lapsed since the last turtle sighting.	**EPS 111**: The acoustic source will be shut-down, or start-up will be delayed for 15 minutes if a marine turtle is observed within 100 m of the acoustic source. Operation of the acoustic source using soft-starts may only resume when the turtle has been observed to move outside the 100 m Shut-down Zone, or when 15 minutes have lapsed since the last turtle sighting	MFOs daily and weekly logs confirm marine turtle procedures were implemented.	MFOs SEA CSR Vessel Master
Policy Statement 2.1: Part B.1 – Marine Mammal Observers.	**EPS 112**: Marine mammal observations made during the Otway Basin 3D MC MSS will be undertaken by dedicated, trained and experienced MFO. All MFOs must: • Have proven 'at sea' experience in whale identification and behaviour, and distance estimation; and	Procurement process for engaging MFOs includes the provision of compliant CVs. Induction records outline qualifications/training of each MFOs.	TGS VOM SEA MFOs

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
The use of suitably trained, dedicated and experienced MFOs to undertake visual observations for whales and ensure that the appropriate mitigation measures outlined in this EP are implemented. MFOs onboard survey vessels to maintain vigilance for SBT while conducting watches for other marine fauna.	• Be confident in the identification of those species that the EP predicts will be present in the OA; and • Hold a JNCC Marine Mammal Observer certification (or equivalent).		
	EPS 113: The lead MFO on the Seismic Vessel must have logged a minimum of 20 weeks' relevant sea-time engaged in marine seismic survey operations in Australian waters as an MFO.	Procurement process for engaging MFOs includes the provision of compliant CVs. Induction records outline qualifications/training of each MFOs.	TGS VOM SEA MFOs
	EPS 114: A minimum of two dedicated, trained, and experienced MFOs will be onboard the Seismic Vessel at all times, with at least one MFO on the bridge of the Seismic Vessel during daylight hours for the visual detection of marine mammals.	Induction records outline qualifications/training of each MFOs. MFOs daily and weekly logs confirm two MFOs were on board the Seismic Vessel to complete daylight visual observations.	TGS VOM SEA MFOs
	EPS 115: Two dedicated, trained, and experienced MFOs will be onboard the Attending Support Vessel at all times, with at least one MFOs on the bridge of the Attending Support Vessel during daylight hours for the visual detection of marine mammals.	MFOs daily and weekly logs confirm two MFOs were on board the Attending Support Vessel to complete daylight visual observations.	TGS VOM SEA MFOs
	EPS 116: MFOs onboard survey vessels are to maintain vigilance for SBT while conducting watches for other marine fauna. Sightings will be reported to ASBTIA within 24-hours of the observation being made.	MFOs daily and weekly logs document any SBT sightings Documentation of consultation, consultation log demonstrates compliance with notification of SBT sightings to ASBTIA.	MFOs SEA CSR Vessel Master EA
Policy Statement 2.1: Part B.2 – Night-time/Poor Visibility. During these periods, operations may proceed provided there have not been three or more whale instigated power-down or shut-downs during the preceding 24-hour period; or no BW/PBW or SRW shut-downs in the preceding 24 hours within 32 km and 42 km (respectively) of the planned acquisition (i.e. the survey lines that will occur during the hours of darkness or the period of low visibility).	**EPS 117**: Poor Visibility or night-time operations may occur provided that: • that there have not been three or more whale instigated power-down or shut-down situations during the preceding 24-hour period; and • that no BW/PBW shut downs have been instigated during the preceding 24 hours within 32 km of the planned acquisition (i.e. the survey lines that will occur during the hours of darkness or the period of low visibility); and • that no SRW shut downs have been instigated during the preceding 24 hours within 42 km of the planned acquisition (i.e. the survey lines that will occur during the hours of darkness or the period of low visibility).	MFOs daily and weekly logs confirm night time and poor visibility procedures were implemented	SEA MFO PAM Operator Vessel Master CSR
A PAM System will run 24-hours per day on the Seismic Vessel during the Otway Basin 3D MC MSS, with dedicated, trained, and experienced PAM Operators conducting acoustic monitoring for the presence of cetaceans while the acoustic source is active and during the 30 minutes before the commencement of any Soft Start Procedures. At least two dedicated, trained, and experienced PAM Operators will be on the Seismic Vessel for the duration of the Otway Basin 3D MC MSS, with at least one PAM Operator maintaining acoustic watch at all times while the acoustic source is active and during the 30 minutes prior to the commencement of any Soft Start Procedure.	**EPS 118**: PAM will be implemented on the Seismic Vessel and will operate 24-hours per day for the duration of the Otway Basin 3D MC MSS while the acoustic source is in the water and during the 30 minutes before the commencement of any Soft-start Procedure.	PAM daily and weekly logs confirm PAM is operational while the acoustic source is in the water and at least one PAM Operator maintains 'acoustic watch' at all times.	TGS VOM SEA PAM Operator Vessel Master CSR
	EPS 119: Two trained and experienced PAM Operators will be on board the Seismic Vessel for the duration of the Otway Basin 3D MC MSS. At least one PAM Operator will maintain 'acoustic watch' at all times while the acoustic source is in the water and during the 30 minutes before the commencement of any Soft-start Procedure.	Induction records outline qualifications/training of each PAM Operator. PAM daily and weekly logs confirm two PAM Operators were on board the Seismic Vessel, with at least one PAM Operator maintaining 'acoustic watch' at all times.	TGS VOM SEA PAM Operator Vessel Master CSR
	EPS 120: All PAM Operators will need to be able to demonstrate competency in the acoustic identification of the species that are likely to be present during the Otway Basin 3D MC MSS, and in interpreting acoustic software and estimating distance to any detected whale calls.	Procurement process for engaging PAM Operators includes the provision of compliant CVs. Induction records outline qualifications/training of each PAM Operator. Policy Statement 2.1: B.6 Adaptive Management Measures: southern right whales Adaptive management controls will be implemented for SRW in the following circumstances: • If higher than anticipated numbers of SRWs are observed (three or more SRW instigated shut-downs are made during the preceding 48 hour period); or • If a SRW mother-calf pair is observed from the Seismic Vessel or the Attending Support Vessel.	**EPS 140**: If three or more SRW instigated shut-downs are made during the preceding 48-hour period at any time or location during the Otway Basin 3D MC MSS, the following adaptive management controls will apply: • Acquisition in the SRW Aggregation BIA/buffer must cease; • Low Visibility or Night-time Operations must cease; • The acoustic source will be shut-down and the Seismic Vessel will relocate to another area at least 42 km away from the last SRW sighting, and outside of the SRW Ag BIA/buffer, before commencing Pre Start-up Visual Observations and Soft Start Procedures. If relocation of the seismic vessel is not possible, then acquisition will cease and will not recommence until 24 hours have elapsed and no SRW has been detected in the 7 km Extended Shut-down Zone; and • Normal operations may only resume after 24 hours of no SRW instigated shut downs.	MFOs daily and weekly logs confirm that Adaptive Management Measures for SRW were implemented if required.	SEA MFOs Vessel Master CSR
	EPS 141: If a SRW mother and calf pair is observed from the Seismic Vessel or the Attending Support Vessel at any distance during the Otway Basin 3D MC MSS, the acoustic source will be immediately shut-down and the Seismic Vessel will relocate to another area at least 42 km away, and outside of the SRW Ag BIA/buffer, before commencing Pre Start-up Visual Observations and Soft Start Procedures. If relocation of the seismic vessel is not possible, then acquisition will cease and will not recommence until 24 hours have elapsed and no SRW has been detected in the 7 km Extended Shut-down Zone.	MFOs daily and weekly logs confirm that Adaptive Management Measures for SRW were implemented if required.	SEA MFOs Vessel Master CSR
	EPS 142: When species identification is uncertain, a precautionary approach will be taken, and the most conservative option in accordance with the additional management procedures for BW/PBW or SRWs will be followed until identification is otherwise confirmed.	MFOs daily and weekly logs confirm that Adaptive Management Measures for SRW were implemented if required and where species identification was uncertain.	SEA MFOs Vessel Master CSR
Policy Statement 2.1: B.6 Adaptive Management Measures: other whales Adaptive management controls will be implemented for other whales in the following circumstances: • If higher than anticipated numbers of other whales are observed (three or more instigated shut downs are made during the preceding 24 hour period); or • If an 'other whale' mother-calf pair is observed within 12 km of the active acoustic source.	**EPS 143**: If three or more 'other whale' instigated shut-downs occur within a 24-hour period, the Seismic Vessel will relocate at least 12 km in the direction away from the sightings before commencing Pre Start-up Visual Observations and Soft Start Procedures	MFOs daily and weekly logs confirm that Adaptive Management Measures for 'other whales' were implemented if required.	SEA MFOs Vessel Master CSR
	EPS 144: If an 'other whale' mother and calf pair is observed within 12 km of the active acoustic source during the Otway Basin 3D MC MSS, the acoustic source will be immediately shut down and the Seismic Vessel will relocate to another area at least 12 km away from the last recorded position of the mother-calf pair before commencing Pre Start-up Visual Observations and Soft Start Procedures.	MFOs daily and weekly logs confirm that Adaptive Management Measures for 'other whales' were implemented if required.	SEA MFOs Vessel Master CSR

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
Additional Management Measures – Blue Whales/Pygmy Blue Whales to allow Biologically Important Behaviours to Continue: • No operation of the acoustic source within 16 km of any BW/PBW BIAs during the period January to June (inclusive) which represents the peak foraging season during which BW/PBW are expected to consistently be present at foraging areas in and around the OA at elevated densities. The only exception allowed relates to the acquisition of the 2D tie line. • Implementation of an Extended 7 km Shut-down Zone[AC]; • Additional MFO observation effort (including aerial surveys); and • Implementation of adaptive management measures.	**EPS 145**: A 16 km buffer will be established around all BW BIAs where they overlap or approach the OA. The Seismic Vessel will not activate the acoustic source(s) within any BW BIAs/buffer from January to June (inclusive). The only exception allowed relates to the acquisition of the 2D tie line in accordance with the criteria outlined in **EPS 162 - 163.**	MFOs daily and weekly logs confirm that Additional Management Measures for BW/PBW were implemented when required.	SEA MFOs Vessel Master CSR
	EPS 146: During the 'foraging shoulder season' months of September to December and July the seismic vessel is permitted to operate in the BW BIAs/buffer in accordance with the following protocols: • All reasonable efforts will be made to ensure that aerial surveys will be conducted to assist with the detection of BW/PBW in the BW BIAs/buffer during the 'foraging shoulder season'. Within the seven days prior to commencement of any acquisition in the BW BIAs/buffer aerial surveys will be flown, if possible, to identify any BW/PBWs that may be present. Any such detections will result in acquisition within the BW BIAs/buffers being redirected away from areas in which such detections have been made. The intent of this control is to allow TGS to respond adaptively to detections of BW/PBWs in the BW BIAs/buffer by relocating to parts of the BW BIAs/buffer where potential impacts on BW/PBWs are less likely. • If the requirement for aerial surveys as outlined in (a) above cannot be achieved, no low visibility or night time operations may occur inside the BW BIAs/buffer until such time as the aerial survey requirement is met. • Aerial survey efforts will concentrate on the area of the BW BIAs/buffer nearest to the proposed start up location and/or those waters that will be subject to acquisition in the first 24 hours of planned seismic operations. Throughout the period in which acquisition is underway, aerial surveys will be flown periodically as weather permits to support the detection of BW/PBW and to redirect seismic survey efforts in order to avoid BW/PBW that are present. • Aerial surveys must be undertaken by two experienced observers from a suitable aircraft. At least one of these observers must demonstrate previous experience in the detection and identification of BW/PBW from the air.	MFOs daily and weekly logs confirm that Additional Management Measures for BW/PBW were implemented when required.	SEA MFOs Vessel Master CSR
	EPS 147: Start-up (via soft start) can only commence in the BW BIAs/buffer during the 'foraging shoulder season' if the following criteria are met: • A minimum of two hours of daylight remain before nightfall; • Good sightings conditions prevail that allow visual observations of the Extended Observation Zone; • MFOs on board the Seismic Vessel and the EOZ Support Vessel have completed at least 30 minutes of pre-start observation procedures and confirmed no BW/PBW have been sighted; and • The start-up location does not occur within 32 km of an area where a BW/PBW detection has been made in the last four days.	MFOs daily and weekly logs confirm that Additional Management Measures for BW/PBW were implemented when required.	SEA MFOs Vessel Master CSR
	EPS 148: Low Visibility or Night-time Operations may occur provided that no BW/PBW shut-downs have been instigated during the preceding 24 hours within 32 km of the planned acquisition (i.e. the survey lines that will occur during the hours of darkness or the period of low visibility).	MFOs daily and weekly logs confirm that Additional Management Measures for BW/PBW were implemented when required.	SEA MFOs Vessel Master CSR
	EPS 149: A 7 km Extended Shut-down Zone for BW/PBW will be implemented throughout the entire OA (including the BW BIAs/buffer).	MFOs daily and weekly logs confirm that Additional Management Measures for BW/PBW were implemented when required.	SEA MFOs Vessel Master CSR

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
	EPS 150: If a BW/PBW is detected in the 7 km Extended Shut-down Zone during the survey the acoustic source will be immediately shut down and the seismic vessel will relocate to another area at least 32 km away from the last PBW sighting before commencing Pre Start-up Visual Observations and Soft Start Procedures. If relocation of the seismic vessel is not possible, then acquisition will cease and will not recommence until 24 hours have elapsed and no BW/PBW has been detected in the 7 km Extended Shut-down Zone.	MFOs daily and weekly logs confirm that Additional Management Measures for BW/PBW were implemented when required.	SEA MFOs Vessel Master CSR
	EPS 151: A Start-up Delay will occur if a BW/PBW enters or is detected in the 7 km Extended Shut-down Zone during the soft start, and soft start procedures may only resume once the BW/PBW is observed to move outside this Shut-down Zone or when 30 minutes have lapsed since the last BW/PBW sighting.	MFOs daily and weekly logs confirm that Additional Management Measures for BW/PBW were implemented when required.	SEA MFOs Vessel Master CSR
	EPS 152: Shape files will be loaded onto the survey vessels' navigation system outlining the BW BIAs and 16 km buffer, against the boundary extents of the OA and AA.	Exclusion polygons on survey vessel's navigation system.	SEA MFOs Vessel Master CSR
Additional Management Measures – Southern Right Whales to allow Biologically Important Behaviours to Continue: • No operation of the acoustic source within 42 km of the SRW Aggregation BIA during the core aggregation months of May to September; • Implementation of an Extended 7 km Shut-down Zone[AC]; • Additional MFO observation effort (including aerial surveys); and • Implementation of adaptive management measures.	**EPS 153**: A 42 km buffer will be established around the SRW Ag BIA where it approaches the OA. The Seismic Vessel will not activate the acoustic source(s) within the SRW Ag BIA/buffer from May to September (inclusive)	MFOs daily and weekly logs confirm that Additional Management Measures for SRWs were implemented when required.	SEA MFOs Vessel Master CSR
	EPS 154: During April and October (shoulder aggregation months) the Seismic Vessel is permitted to operate in the SRW Ag BIA/buffer in accordance with the following protocols: • All reasonable efforts will be made to ensure aerial surveys will be conducted to assist with the detection of SRWs in the SRW Ag BIA/buffer during April and October. Within the seven days prior to commencement of any acquisition in the SRW Ag BIA/buffer, aerial surveys will be flown, if possible, to identify any SRW that may be present. Any such detections will result in acquisition within the SRW Ag BIA/buffer being redirected away from areas in which such detections have been made. The intent of this control is to allow TGS to respond adaptively to detections of SRWs in the SRW Ag BIA/buffer by relocating to parts of the OA where potential impacts on SRWs are less likely. • If the requirement for aerial surveys as outlined above cannot be achieved, no low visibility or night time operations may occur inside the BW BIAs/buffer until such time as the aerial survey requirement is met • Aerial survey efforts will concentrate on the area of the SRW Ag BIA/buffer nearest to those waters that will be subject to acquisition in the first 24 hours of planned seismic operations. Aerial surveys should also monitor any nearby waters of the known core range BIA that acquisition will soon occur in. • Throughout the period in which acquisition in the SRW Ag BIA/buffer is underway, aerial surveys will be flown periodically as weather permits to support the detection of SRWs and to redirect seismic survey efforts in order to avoid areas where SRWs are present. • Aerial surveys must be undertaken by two experienced observers from a suitable aircraft. At least one of these observers must demonstrate previous experience in the detection and identification of SRW from the air.	MFOs daily and weekly logs confirm that Additional Management Measures for SRWs were implemented when required.	SEA MFOs Vessel Master CSR
	EPS 155: Start-up (via soft start) can only commence in the SRW Ag BIA/buffer during April and October if the following criteria are met: • A minimum of two hours of daylight remain before nightfall; • Good sightings conditions prevail that allow visual observations of the Extended Observation Zone; • A Support Vessel is available to undertake the requisite marine mammal monitoring;	MFOs daily and weekly logs confirm that Additional Management Measures for SRWs were implemented when required.	SEA MFOs Vessel Master CSR

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
	• MFOs on board the Seismic Vessel and the EOZ Support Vessel have completed at least 30 minutes of pre-start observation procedures and confirmed no SRWs have been sighted; and • The start-up location does not occur within 42 km of an area identified by aerial surveys as an area where a SRW mother-calf detection has been made in the last four days.		
	EPS 156: Low Visibility or Night-time Operations may occur provided the no SRW shut-downs have been instigated during the preceding 24 hours within 42 km of the planned acquisition (i.e. the survey lines that will occur during the hours of darkness or the period of low visibility.	MFOs daily and weekly logs confirm that Additional Management Measures for SRWs were implemented when required.	SEA MFOs Vessel Master CSR
	EPS 157: A 7 km Extended Shut-down Zone for SRWs will be implemented throughout the entire OA (including the SRW Ag BIA/buffer). If a SRW is detected in the 7 km Extended Shut-down Zone during the survey the acoustic source will be immediately shut down and the seismic vessel will relocate to another area at least 11 km away from the last SRW (unaccompanied) sighting before commencing Pre Start-up Visual Observations and Soft Start Procedures. Note that this distance increases to 42 km if a calf is present as described in **EPS 67**.	MFOs daily and weekly logs confirm that Additional Management Measures for SRWs were implemented when required.	SEA MFOs Vessel Master CSR
	EPS 158: A Start-up Delay will occur if a SRW enters or is detected in the 7 km Extended Shut-down Zone during soft start, and soft start procedures may only resume once the SRW is observed to move outside this Shut-down Zone or 30 minutes have lapsed since the last SRW sighting.	MFOs daily and weekly logs confirm that Additional Management Measures for SRWs were implemented when required.	SEA MFOs Vessel Master CSR
	EPS 159: Shape files will be loaded onto the survey vessels' navigation system outlining the SRW Aggregation BIA and 42 km buffer, against the boundary extents of the OA and AA.	Exclusion polygons on survey vessel's navigation system.	SEA MFOs Vessel Master CSR
Additional Management Measures – other whales: A 2 km Extended Shutdown Zone[AC] for 'other whales' will be implemented throughout the entire OA at all times. On this basis a low power zone is deemed unnecessary. Soft starts at night and during periods of low visibility will also be limited in accordance with EPS 83[AC]	**EPS 160**: A 2 km Extended Shut-down Zone for 'other whales' will be implemented throughout the entire OA at all times.	MFOs daily and weekly logs confirm the Additional Management Measure for 'other whales' was implemented.	SEA MFOs Vessel Master CSR
Additional Management Measures –2D tie Line acquisition inside any BIA/buffer: 2D tie line acquisition inside any BIA/buffer (the BW BIAs/buffer and the SRW Ag BIA) will only be permitted to occur in accordance with EPS 162 - 163.	**EPS 161**: 2D tie line acquisition inside any BIA/buffer will only be permitted to occur: • In daylight hours, and • Two MFOs must be on duty on the Seismic Vessel and • Two MFOs must be on-duty on the Attending Support Vessel.	MFOs daily and weekly logs confirm the Additional Management Measure for 2D tie line acquisition inside the BW BIAs/buffer and the SRW Ag BIA was implemented.	SEA MFOs Vessel Master CSR
	EPS 162: 2D tie line acquisition inside any BIA/buffer can occur at any time providing the following criteria are met: • An aerial survey has been conducted within 4 days of such operations commencing and no baleen whales have been detected. This aerial survey must focus on the area of planned acquisition that overlaps the BIA/buffer and must extend to at least 42 km on either side of the planned 2D sail line; • 2D tie line acquisition inside any BIA/buffer must not occur for more than 12 hours total within any 24 hour period; • The Extended Observation Zone as described in BMP 4 is implemented; and	MFOs daily and weekly logs confirm the Additional Management Measure for 2D tie line acquisition inside the BW BIAs/buffer and the SRW Ag BIA was implemented. 7.2.8 Acoustic Disturbance Impact and Risk Summary

Based on the findings of this EP, with the implementation of the control measures, underwater noise emitted from the acoustic source during the Otway Basin 3D MC MSS is considered to have (at most) a **Moderate** residual risk to the identified receptors (i.e. environmental and other marine users). Consequences of predicted effects will generally be minor and short-term with regards to displacement of marine mammals and fish away from the acoustic source.

The suite of control measures determined to be adopted have been developed in accordance with industry best practice and relevant legislation. In accordance with the Risk Ranking Descriptions in **Table 34**, where risk cannot be reduced to '**Low**', additional control measures must be evaluated to determine whether the risk is reduced to **ALARP**.

Additional controls have also been evaluated to determine whether they are effective and practicable to implement in **Table 42**. Where they are determined to effectively reduce the environmental impact and risk, and are practicable to implement, they have been adopted. Consequently, it is considered that the environmental impacts and risks on the identified receptors arising from the acoustic disturbance to the marine environment arising from the Otway Basin 3D MC MSS, are reduced to **ALARP**.

In accordance with the acceptability requirements prescribed in **Section 6.4,** the suite of control measures, are considered appropriate to manage the impacts arising from the acoustic disturbance to the marine environment on all receptors, specifically marine fauna, commercial fishers, and divers to an **Acceptable Level.**

7.3 Routine Permissible Waste Discharges

7.3.1 Description of Source of the Impact and Risk

The source of routine permissible waste discharges falls into three categories:

- Biodegradable waste (sewage, greywater and galley waste such as putrescible food waste);
- Deck drainage; and
- Bilge water.

The primary forms of biodegradable wastes produced during the Otway Basin 3D MC MSS are sewage, greywater and galley wastes, with these wastes originating from processes such as ablution, laundry, and galley activities. A typical Seismic Vessel is likely to have a maximum daily sewage discharge capacity of approximately 15 m^3, and the typical discharge capacity for the support vessel/s is approximately 4.2 m^3. The actual daily volumes of sewage and greywater generated during the Otway Basin 3D MC MSS will be directly related to the number of personnel onboard (0.45 m^3 of sewage/greywater per day[40] (NERA, 2018)). Putrescible waste discharges are in the order of 1 – 2 kg per person per day (NERA, 2018).

The composition of sewage, putrescible wastes and grey water may include (NERA, 2018):

- Physical particulate matter such as solids composed of floating, settleable, colloidal and dissolved matter;
- Chemicals including nutrients, organics, and inorganics; and
- Biological pathogens (e.g. bacteria, viruses, protozoa, parasites, etc.).

The other source of permissible waste discharges are deck drainage and bilge water. Ongoing cleaning and maintenance operations around the vessels, as well as deck drainage from rain or spray will generate deck waters which may contain remnants of spilt materials, detergents, oils and smaller solid materials (garbage). Larger chemical spills would be contained and/or cleaned up prior to entering the deck drainage systems as per the vessels emergency spill/pollution plans. Bilge water is drainage water and other fluids captured in a closed system, often from engine or machinery spaces within the vessel, for treatment prior to discharge at sea, or stored for discharge at port – as per requirements of MARPOL Annex 1. The contaminant profile of bilge water may comprise cleaning chemicals, hydrocarbons and heavy metals.

[40] This volume has been taken as a worst-case from the NERA '*Planned discharge of sewage, putrescible waste and grey water*' Environment Plan Reference Case which estimates the total volume generated to range from 0.04 – 0.45 m^3 per person per day. The worst case of 0.45 m^3 has been used for these calculations.

Dilution of discharges from moving vessels, such as will be the case for the Otway Basin 3D MC MSS, occurs immediately. Moving ships displace a volume of water that is immediately refilled as the ship passes, resulting in mixing within the wake astern of the ship. A ship with a large cross-sectional area (draft and width) will create more mixing than a smaller ship (Loehr *et al*., 2006). Vigorous mixing occurs in the turbulent wake and extends horizontally beyond the beam (or width) and vertically below the draft (or depth) of the vessel (Loehr *et al*., 2006). Loehr *et al*. (2006) describe simple equations to conservatively describe the dilution factors for wastewater discharges from moving large and small cruise ships. Based on these equations, dilution factors for an effluent discharge of 62 m^3/day are estimated to be > 1,000,000. NERA (2018) states that a 150 m^3 discharge of sewage and greywater from a fixed-point discharge will be at background levels within 500 m from the point of discharge. A combined maximum discharge of 62 m^3/day is estimated for the seismic vessels, therefore it is anticipated that background levels will be observed considerably closer than 500 m and likely within 200 – 300 m of the discharges.

Non-biodegradable wastes, such as garbage, will also be generated during routine operations onboard the seismic vessels. The discharge to sea of all types of garbage is prohibited under MARPOL Annex V unless explicitly permitted under the Annex. Garbage onboard the survey vessels such as plastics, synthetic ropes, cooking oils, paper and cardboards, rags, packaging materials, polystyrenes/foam and wood are prohibited from being discharged into the marine environment, and these materials will be retained onboard the vessels and stored for later disposal onshore at suitable waste facilities.

7.3.2 Evaluation of Known and Potential Impacts and Risks to Environmental Receptors

Using the information presented in **Section 4** to **Section 5**, the impact and risk assessment has been undertaken for those receptors determined to be relevant to the activity as listed in **Table 88.**

Table 88 Environmental Receptors Assessed

Receptor	Section reference
Marine Environmental Quality	**Section 7.3.2**
Plankton	
Benthic Habitats	
Benthic Invertebrates	
Non-listed Marine Fauna	
Listed Marine Fauna	

Any marine receptor that resides in the water column and which could uptake contaminants through a dissolved, particulate, or dietary exposure pathway may be affected by discharges. Impacts from discharges may include (NERA, 2018):

- Ecosystem health values being compromised in the vicinity of the waste discharge;
  - Eutrophication and associated changes in the abundance and biomass of biota (e.g. enhanced growth of phytoplankton in the water column), change in patterns of biological diversity (reduced species diversity with shifts towards fewer well adapted species), and/or increased biological and chemical oxygen demand; and
  - Direct and indirect toxicity to marine flora and fauna (including acute lethal and/or chronic sub-lethal effects) for example through exposure to chemicals used to treat wastewater and waste systems.

- Primary industry values may be impacted, for example, seafood caught within the immediate vicinity of the discharge may not be safe for human consumption; and
- Recreation and aesthetic values may be affected such as contamination of water with human pathogens making swimming areas unsuitable.

The level of impact is directly related to the volume of the contaminant, the volume of the receiving water body, its toxicity, the sensitivity of the receiving environment, and the types of organisms present. Permissible discharges can affect organisms across all trophic levels but are likely to have immediate effects on primary producers, such as phytoplankton, which in turn influence higher trophic levels. Initial impacts are most likely to affect organisms within the water column due to the depths in which the vessels will be operating. The shallowest depths (approximately 200 m) occur along the eastern margins of the OA. It is unlikely that the benthic organisms at these depths (and greater) will be affected by any discharges occurring from the survey vessels.

The main environmental impacts associated with the discharge of routine permissible wastes are localised increase in nutrients, (particularly phosphorus and nitrogen) which can trigger excessive algal growth leading to the eutrophication of waters (Perić, 2016; Wilewska-Bien *et al.*, 2016). Excessive algal growth can lead to algal blooms. The resultant decomposition of organic bloom material by bacteria in the water column can lower the oxygen concentration of waters, particularly in low flow environments, leading to anoxic conditions. When algal blooms die and settle to the sea floor the organic material is decomposed by bacteria on the seabed, excessive amounts can lead to anoxic conditions within the marine sediments.

Plankton communities have developed to rapidly respond to favourable conditions such as an influx of nutrients, as often occurs in areas of natural upwelling of nutrients, such as the Bonney Coast upwelling, located just to the north and north-west of the OA. In areas of seasonal upwelling of nutrients, once the favourable conditions cease, plankton populations collapse and/or return to previous conditions (NERA, 2018). Thus, an equilibrium exists between primary and secondary producers (Kämpf *et al*., 2023). Any potential change to phytoplankton or zooplankton abundance, due to the discharge of permissible wastes will be localised and short lived, returning to background conditions within tens to a few hundred meters of the discharge location (Parnell, 2003). Furthermore, the environment in which the vessels will be operating in is a high flow environment where dispersal and dilution of biodegradable waste will be maximised. Localised nutrient enrichment is therefore minimised. Primary productivity in the South-east AMPs is predominately derived from oceanic sources and is strongly influenced by climatic and oceanographic factors and is therefore considered relatively resilient to human impact (NOO, 2001). Nutrients are generally concentrated at the shelf edge, with shallower coastal areas naturally more oligotrophic, and consequently more susceptible to degradation from excessive nutrient loading from terrestrial sources, arising from urban and intensive agriculture areas (NOO, 2001).

Shallow water environments, such as those encountered in the West Tasmania Canyons KEF along the eastern portion of the OA, are the environments most vulnerable to pollution arising from the discharge of waste products from shipping vessels. Deeper water environments, such as canyons and slope features, which predominate within the OA are more resilient due the depths and strong oceanic currents present which increase the assimilative capacity of the environment, thereby reducing any potential impacts. Deteriorating water quality has been identified as a threat to marine species, such as marine turtles, whales, dolphins, and seabirds identified within the OA (DNP, 2013). The EPBC Act Conservation Management Plans and Recovery Plans advise implementing measures to manage and reduce, where possible, waste generation to avoid adverse impacts on these species.

Cruise ships are identified as an emerging pressure in the South-east Marine Parks, where the region is used as a gateway to the Antarctic via Melbourne and Hobart (NOO, 2001). Cruise ships can accommodate from 1,000 to > 3,500 persons per ship. Marine pollution such as marine debris and the discharge of oils, chemicals or wastes, from commercial and recreational vessels has been identified as a pressure in South-east AMPs. Recreational and commercial boating are sources of waste that can have a direct physical impact on marine species. Discarded or lost nets and pots, nylon rope and polypropylene strapping bands can cause physical entanglement of fish, sea mammals and birds. Plastic and other debris can be ingested by birds and mammals. Microplastics are an emerging contaminant that can be ingested by fish and smaller organisms. Debris from boats can smother benthic fauna and act as a source of transfer of exotic organisms (NOO, 2001). There will be no discharge of marine debris from the vessels and every effort will be made to ensure no accidental loss of debris from the survey vessels (see **Section 8.5**).

Habitat modification and degradation has been identified as a threat to sensitive fish and mammal species. It is unlikely that any discharge of permissible waste discharges will lead to changes in benthic or pelagic habitats, that would adversely impact these species as the volumes of waste proposed to be discharged are well within the assimilative capacity of the receiving environment.

The discharge of food wastes can lead to increased scavenging behaviour around vessels by seabirds and fish, sometimes leading to animals following the vessel for significant distances. Albatross bird species are known to actively follow ships and boats. It is known that this is not an instinctive behaviour, but a learned behaviour as they have associated ships and boats with the presence of food, from fish on longlines and nets to kitchen scraps thrown overboard (Weimerskirch, 2023). Petrels and shearwaters are known to actively and aggressively pursue bait from long line fishing from commercial and recreational fishing boats (Friesen *et al*., 2017). Fatalities are mostly associated with entanglement in fishing hooks and lines, thus bird fatalities, as a result of following vessels in search of food scraps are highly unlikely.

Discharges from vessels are most problematic when they occur within enclosed inland waters and/or semi-enclosed coastal waters with minimal flushing (Koboevic *et al*., 2022), or within areas with high conservation values such as marine parks (Byrnes and Dunn, 2020). Receiving waters with high flushing capacities can dilute or eliminate most pollutants associated with waste discharges (Koboevic *et al*., 2022). The wind, waves and currents present in the offshore marine waters of the OA (**Section 4.3.3**) will ensure that any discharges are rapidly mixed. As a result of the highly dispersive environment within the OA, nutrients from the discharge of permissible waste will not accumulate or lead to eutrophication of waters surrounding the discharge point. As the majority (~ 90%) of the OA is within waters >1000 m, discharges are unlikely to settle on the seabed and affect benthic organisms.

The disposal of waste from normal operations of vessels is permitted within AMPs as long as the disposal is compliant with MARPOL requirements (DNP, 2013). There will be no discharge of routine permissible waste within the boundaries of the Nelson AMP and Zeehan AMP. All permissible discharges from the survey vessels will be compliant with the requirements of MARPOL. Therefore, there will be no impact on the sensitivities and values within the AMPs located within the OA, nor are any adverse impacts anticipated within the wider OA from routine permissible waste discharges from the survey vessels.

Based on the control measures that will be implemented during the Otway Basin 3D MC MSS for routine permissible waste discharges (**Section 7.3.4**), it is considered that the consequence of impact is *Negligible*, with a likelihood of seeing a measurable impact being *Unlikely* which results in an overall risk ranking of **Negligible**.

7.3.3 Decision Context

The decision context for routine permissible waste discharges has been assessed as Type A for all receptors, given the predicted impacts and risks are well understood and uncertainty is minimal, with little or no interest from relevant persons.

7.3.4 Identification of Control Measures, Residual Risk Assessment and Demonstration of ALARP

A Hierarchy of Controls methodology (**Table 89**) has been used to assess control measures to determine the benefits in their use towards risk reduction. The control measures that will be implemented during the Otway Basin 3D MC MSS to manage the impacts from routine permissible waste discharges to **ALARP** are included in **Table 90**. The control measures that will be adopted are those that have been assessed and characterised as effective and practicable to implement.

Table 89 Hierarchy of Control Measures for Routine Permissible Waste Discharges

Eliminate	As discussed within **Table 90**, the vessels are required to be manned at all times which means the generation of sewage, greywater and galley waste cannot be eliminated. Alternatively, waste could be stored onboard the vessels and transported to onshore licensed facilities for disposal. This would add significant operational costs, time, and additional health and safety risks. Therefore, it was considered that elimination of permissible waste discharge was not practicable. TGS will eliminate the discharge of all routine permissible wastes within the boundaries of the Nelson AMP and Zeehan AMP to ensure there are no impacts to the sensitivities within these areas resulting from routine permissible waste discharges.
Substitute	Limited practicable substitutes for discharge of this waste are available.
Reduce	The impact from the discharge of routine permissible wastes will be reduced by the implementation of the adopted control measures, as described within **Table 90.** For example, the oil content within oily water discharge will be reduced to 15 ppm through an approved oily water separator; an approved comminuting and disinfecting system will be used to treat sewage; and a grinder/comminuter will be used where required to reduce the potential impacts from the discharge of food waste on the marine environment.
Mitigate	To mitigate the effects of routine permissible waste discharges, separation distances have been defined for sensitive receptors, in accordance with the legislative requirements and good industry practice. For example, no untreated sewage and putrescible wastes will be discharged within 12 NM from land and no treated sewage and putrescible wastes will be discharged within 3 NM from land to protect nearshore coastal margins from potential nutrient enrichment.

Table 90 Assessment of Control Measures for Routine Permissible Waste Discharges

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Legislative Requirements:			
The Otway Basin 3D MC MSS will be undertaken in accordance with the approved EP.	P = Yes E = Effective	All vessels undertaking an offshore activity in waters between 3 and 200 NM must undertake that activity in line with an approved EP. The approved EP outlines the measures that will be taken to ensure that environmental effects from the activity will be reduced to **ALARP** and **Acceptable Levels**, including the management of routine permissible waste discharges.	Yes
All survey vessels will comply with the requirements of MARPOL Annex I (Regulations for the Prevention of Pollution by Oil), Marine Order 91 (Marine Pollution Prevention – Oil) and *Protection of the Sea* (Prevention of Pollution from Ships) *Act 1983,* including*:* In accordance with MARPOL Annex I and Marine Order 91, vessels ≥ 400 gross tonnes will: • Have an oil discharge monitoring and control system and oil filtering equipment on-board. • The oil discharge monitoring and control system will be maintained and operated to the 15 ppm standard. • Hold a current International Oil Pollution Prevention (**IOPP**) Certificate. • Maintain an oil usage management logbook. • Treated bilge water will only be discharged when the vessel is moving, and the oil discharge monitoring and control system and oil filtering equipment is operating. If oil discharge monitoring and control systems and oil filtering equipment is unavailable, bilge water mixtures will be retained onboard for onshore disposal.	P = Yes E = Effective	Vessels used for the survey that are of 400 GRT will have an oil discharge monitoring and control system and oil filtering equipment on board (with related IOPP Certificate) in accordance with the requirements of MARPOL Annex I and AMSA Marine Order 91. Bilge water discharges will be undertaken in accordance with the requirements of MARPOL Annex I and Marine Order 91 to ensure discharges to the marine environment are acceptable or otherwise retained on board for disposal. It is a legislative requirement to meet the relevant aspects of MARPOL Annex I, Marine Order 91 and the PSPPS Act.	Yes
All survey vessels will comply with the requirements of MARPOL Annex IV (Regulations for the Prevention of Pollution by Sewage from Ships) and Marine Order 96 (Marine Pollution Prevention – Sewage), including: • A valid international Sewage Pollution Prevention (**ISPP**) Certificate, as required by vessel class; • Sewage will only be discharged via an IMO-approved sewage treatment plant; or • Comminuted/disinfected sewage via an IMO-approved system will only be discharged when ≥3 nm from land and when the vessel is moving at ≥4 knots; or • Sewage that has not been comminuted/disinfected via an IMO-approved system will only be discharged when ≥12 nm from land and when the vessel is moving at ≥4 knots.	P = Yes E = Effective	Vessels used for the survey that are of 400 GRT or certified to carry more than 15 persons, will have an appropriate sewage treatment plant, sewage comminuting and disinfecting system or sewage holding tank on board (with related ISPP Certificate). Sewage discharges to the marine environment during the survey will be undertaken in accordance with the requirements of MARPOL Annex IV and Marine Order 96, including via approved systems and the required discharge rates to ensure adequate dispersion of discharges to reduce the potential for impacts. It is a legislative requirement to meet the relevant aspects of MARPOL Annex IV and Marine Order 96.	Yes
All survey vessels will comply with the requirements of MARPOL Annex V (Regulations for the Prevention of Pollution by Garbage from Ships) and Marine Order 95 (Marine Pollution Prevention - Garbage), including: • Putrescible waste will be discharged while the vessel is moving and ≥12 nm from the nearest land; or • Putrescible waste will pass through a comminuter or grinder capable of passing through a screen with no opening wider than 25 mm in diameter prior to discharge and discharged while the vessel is moving and ≥3nm from the nearest land.	P = Yes E = Effective	Discharges of putrescible waste will be undertaken in accordance with the requirements of MARPOL Annex V and Marine Order 95. It is a legislative requirement to meet the relevant aspects of MARPOL Annex V and Marine Order 95.	Yes

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Good Industry Practice			
Equipment/machinery involved in the treatment of wastes, such as oil discharge monitoring and control systems, oil filters and comminuters, will maintained and calibrated as per the manufacturers guidelines to ensure they operate effectively.	P = Yes E = Effective	Routine maintenance ensures that the requirements of MARPOL are able to be met. Records of equipment calibration can be retained and checked to confirm that equipment is operating as per the requirements of MARPOL and associated Marine Orders. Good industry practice; environmental benefit outweighs additional cost.	Yes
Equipment/machinery involved in the treatment of wastes will be operated by trained crew who will be instructed at the pre-mobilisation environmental induction on how to comply with the requirements of this EP.	P = Yes E = Effective	It is a standard industry practice to hold inductions for all onboard the vessels, with participation in induction meetings compulsory. During inductions, crew will be made aware of their responsibilities with regard to the management of routine permissible waste discharges to the marine environment. Good industry practice; environmental benefit outweighs additional cost.	Yes
The vessel crew will be made aware of their responsibilities with regard to the management of routine permissible waste discharges to the marine environment during the environmental induction.	P = Yes E = Effective	Environmental inductions are standard industry practice to ensure the health and safety of those onboard and the protection of the environment. During inductions, crew will be made aware of their responsibilities with regard to effects of the discharge of wastes to the marine environment and restrictions around the overboard discharge of waste materials. Participation in inductions is compulsory. Good industry practice; safety benefit outweighs additional cost.	Yes
All storage areas for hazardous substances will be designed and maintained to support some form of containment/bunding.	P = Yes E = Effective	Containment/bunding will be in place around all locations where hazardous substances/materials are stored onboard the vessels to capture any spilled substances/materials and prevent them from entering the marine environment. Good industry practice; environmental benefit outweighs additional cost.	Yes
Deck scupper plugs will be available beside all deck drainage points that lead overboard.	P = Yes E = Effective	Deck scupper plugs allow for drainage to be blocked off, stopping wastes (including hazardous wastes) from entering the marine environment through deck drainage systems. Good industry practice; environmental benefit outweighs additional cost.	Yes
Display of signage notifying vessel crew of disposal requirements.	P = Yes E = Effective	The display of signage notifying crew of disposal requirements is good industry practice and reminds crew of waste disposal requirements/separation etc. Good industry practice; environmental benefit outweighs additional cost.	Yes
Alternatives/Substitutes Controls Considered:			
Eliminate the discharge of sewage, greywater and galley waste to the marine environment through the retention of all liquid wastes on board and, ultimately, transfer to a licensed onshore disposal site.	P = No E = Very Effective	As the vessels is required to be manned, the generation of sewage, greywater and galley waste is unavoidable. Although this would reduce the impact of discharges, the storage of this waste on board the vessels and subsequent transfer to shore will require additional supply journeys to be made throughout the survey, adding significant operational costs (e.g., fuel) and also increasing the environmental and navigational impact and risk associated with the Otway Basin 3D MC MSS. Given the control measures to be adopted commit to the routine discharge of permissible wastes in accordance with MARPOL and associated Marine Orders, the environmental risks associated with this activity are considered low. On this basis, the cost associated with this control measure are considered disproportionate to the benefits gained.	No
Eliminate the discharge deck drainage and bilge water to the marine environment through the retention of all liquid wastes on board and, ultimately, transfer to a licensed onshore disposal site.	P = No E = Very Effective	Maintenance and cleaning required for the safe operation of survey vessels generate water requiring treatment and are unavoidable. Deck drainage arising from rain or spray cannot be eliminated. Although this would reduce the impact of discharges, the storage of this waste on board the vessels and subsequent transfer to shore will require additional supply journeys to be made throughout the survey, adding significant operational costs (e.g. fuel) and also increasing the environmental and navigational impact and risk associated with the Otway Basin 3D MC MSS. Given the control measures to be adopted commit to the routine discharge of permissible wastes in accordance with MARPOL and associated Marine Orders, the environmental risks associated with this activity are considered low. On this basis, the cost associated with this control measure are considered disproportionate to the benefits gained.	No

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Additional Controls Considered			
There will be no planned discharge of routine permissible wastes within the boundaries of the Nelson AMP and Zeehan AMP.	P = Yes E = Effective	AMPs occupy approximately 17% of the OA. These areas are considered to be particularly sensitive and thus it is proposed that no planned discharge of routine permissible wastes within the boundaries will occur, in order to avoid any potential adverse effects within these areas. Routine permissible discharges are expected to be rapidly mixed and diluted by the wind, waves and currents which characterise the offshore marine waters of the OA, before dispersion occurs, and thus no adverse effects are anticipated. As a result of the highly dispersive environment within the OA, toxicants and nutrients from the discharge of sewage will not accumulate or lead to eutrophication of waters surrounding the discharge point or within nearby AMPs. Water quality is not a value cited within the South-east Commonwealth Marine Reserves Network Management Plan (DNP, 2013) for the Zeehan or Nelson AMPs. The disposal of waste from normal operations of vessels is permitted within AMPs as long as the disposal is compliant with MARPOL requirements (DNP, 2013). Although all discharges from the survey vessels will be compliant with the requirements of MARPOL and are not anticipated to cause any potential adverse effects, TGS has committed to not discharge routine permissible wastes within the boundaries of any AMP. Environmental benefits outweigh additional costs.	Yes
There will be no discharge of routine permissible wastes within the boundaries of any KEF.	P = No E = Limited Effectiveness	Part of the West Tasmania Canyons KEF overlaps the OA. This KEF occupies a total area of 289,850 km^2, with approximately 3,770 km^2 located within the OA, equating to approximately 7% of the OA. The bioregion marks a transitional area between deeper offshore waters and the southeast margin of the Australian mainland, with maximum depths of 5,645 m within the canyons. Canyons have steep or rugged topography that provide habitat for sessile invertebrates, such as corals, which in turn attract other organisms and higher order species. Canyons can intensify currents and the concentration of nutrients to enhance productivity and biodiversity. Plumes of sediment and nutrient-rich water can be seen at or near the heads of canyons. Any routine permissible discharges are expected to be rapidly mixed and diluted by the wind, waves and currents which characterise the offshore marine waters of the OA, before dispersion occurs. As a result of the highly dispersive environment within the OA, toxicants and nutrients from the discharge of sewage will not accumulate or lead to eutrophication of waters surrounding the discharge point and will be readily assimilated in the high productivity environment. Furthermore, the depths within the canyons make it highly unlikely that any pollutants will settle on the seafloor within the canyons. It is not considered practicable to limit routine permissible discharges within the boundaries of the West Tasmania Canyons KEF. Given no adverse effects on the sensitivities within the KEF are predicted, the cost to operations associated with storage of wastes or additional journeys to areas of the OA located outside of the KEF are considered grossly disproportionate to the limited environmental benefit gained from implementing the control measure.	No
Residual Risk of Impact (Receptor)	**Consequence**	**Likelihood**	**Residual Risk Ranking**
Marine Environmental Quality	Negligible	Unlikely	Negligible
Plankton	Negligible	Unlikely	Negligible
Benthic Habitats	Negligible	Unlikely	Negligible
Benthic Invertebrates	Negligible	Unlikely	Negligible
Non-listed Marine Fauna	Negligible	Unlikely	Negligible
EPBC Act Listed Marine Fauna	Negligible	Unlikely	Negligible
ALARP Statement			
The decision context has been assessed as Type A and the overall residual risk has been determined to be Negligible. TGS considers the adopted control measures are appropriate to manage the impacts of routine permissible waste discharges during the survey. The proposed control measures have been developed in accordance with the legislative requirements and good industry practice and taking into account the specific environmental, social, economic and cultural characteristics of the OA. No effective and practicable alternative or additional control measures were identified as part of the assessment process. Therefore, the predicted impacts to receptors from routine permissible waste discharges are reduced to **ALARP.**			

7.3.5 Impact and Risk Acceptability

Table 91 Demonstration of Impact and Risk Acceptability for Routine Permissible Waste Discharges

Criteria for Acceptance	Acceptability Summary
Residual Risk Ranking	The Residual Risk has been determined to be Negligible.
Ecologically Sustainable Development	The management of the impacts associated with the Otway Basin 3D MC MSS as a result of routine permissible waste discharges can be carried out in compliance with the five principles of ESD as defined within the EPBC Act. The assessment has not identified any adverse impacts to the principles of ESD, with no threats of serious or irreversible damage, no impacts to biological diversity and ecological integrity, no degradation of inter-generational equity, or negative effects on the social and economic integrity in the short or long-term.
TGS's Internal Context	The proposed management of the risks associated with the establishment of IMS is consistent with TGSs QHSE Policy commitments of: • Protecting the environment; and • Conducting operations in an environmentally sustainable and responsible manner.
Existing Environmental Context	It is considered that the routine discharge of permissible wastes will not result in any significant impact on environmental values or sensitivities within the OA, including protected and non-protected species which inhabit the water column, such as pelagic fish, sharks, marine mammals, marine turtles and seabirds within the wider OA and also within the AMPs and KEFs located within the OA. Given the expected mixing and dispersion of discharged waste and the depths over which the vessels will be operating, it is unlikely that routine permissible waste discharges will impact upon benthic species. By extension, the discharge of routine permissible wastes is not expected to impact significantly on the environmental values and sensitivities, including significant benthic habitats and communities, which comprise the deep canyons of the West Tasmania KEF within the OA. No impacts to other marine users are predicted to occur as a result of the discharge of routine permissible wastes. It is considered that the proposed control measures provide appropriate protection to marine fauna and other marine users from the potential effects associated with the routine discharge of permissible waste. A number of control measures were considered as part of the assessment process, and it was concluded that the addition of any further control measures not already considered would provide little or no additional protection, or the costs would be grossly disproportionate to the benefit gained.
External Context – Management Plans, Species Recovery Plans and Conservation Advice	The residual risk of routine permissible waste discharges has been determined to be Negligible and will not have a significant impact on a matter of national environmental significance in accordance with EPBC Act Policy Statement 1.1. **Species Recovery Plans and Conservation Advices** Routine permissible waste discharges are not considered as a threat requiring additional management under the relevant Management Plans, Species Recovery Plans or Conservation Advices. **AMP Values, Management Prescriptions and IUCN Reserve Management Principles** As there will be no discharge of routine permissible wastes within the boundaries of the Nelson AMP and Zeehan AMP, routine permissible waste discharges are not expected to impact significantly on environmental values or sensitivities at a local or regional level. No population-level impacts or serious irreversible ecological implications are predicted to the values of AMPs. Management of routine permissible discharges during the Otway Basin 3D MC MSS will be in accordance with the MARPOL requirements. **Conservation values and objectives of the South-east Marine Parks Management Plan** Routine permissible waste discharges are not expected to impact significantly on environmental values or sensitivities of the SEMR at a local or regional level.
Social Acceptance – Relevant Person Expectations	Concerns were raised by relevant persons around the potential for rubbish to accumulate on beaches as a result of discharges from the Survey Vessels operating for the Otway Basin 3D MC MSS. TGS has committed to zero rubbish disposed at sea and with the strict control measures (in accordance with industry best practice) in place to ensure rubbish does not enter the marine environment, the risk of environmental impacts relating to waste discharges from Survey Vessels are considered to be at a socially **Acceptable Level.**
External Context – Commonwealth and State Legislative Criteria	TGS will ensure that routine permissible waste discharges (i.e. sewage, food waste, deck drainage and bilge water) will be undertaken in accordance with international conventions and relevant legislation, including: • MARPOL Annex I, Annex IV and Annex V; • Protection of the Sea (Prevention of Pollution from Ships) Act 1983; • Marine Order 91 (Marine Pollution Prevention – Oil), 2014; • Marine Order 95 (Marine Pollution Prevention – Garbage), 2013; and • Marine Order 96 (Marine Pollution Prevention – Sewage), 2013.
Industry Best Practice	The proposed control measures follow industry best practice and best practice guidelines, including: • The IAGC Environmental Manual for Worldwide Geophysical Operations which provides guidance on waste management, including, but not limited to: • Vessels having a Waste or Garbage Management Plan to effectively manage waste in line with MARPOL regulations as well as local legislation;

Criteria for Acceptance	Acceptability Summary
	• Waste that cannot be incinerated will be segregated and stored for disposal ashore; • Prior to discharge, oily water is processed to remove oil to less than 15 ppm; • Greywater and sewage are dealt with according to MARPOL; and • The APPEA Code of Environmental Practice includes an objective to reduce the impact of routine waste discharges on the marine environment to **ALARP** and to an **Acceptable Level** by ensuring discharges are in accordance with legislative requirements and predicted levels.
ALARP	Total elimination of all impacts associated with routine permissible waste discharges cannot be achieved, as the generation of sewage, greywater and galley waste is unavoidable and will be discharged to sea daily in relatively small volumes, with no practicable alternatives. However, these discharges will be in accordance with the requirements of the MARPOL 73/78 Convention (as implemented in Commonwealth waters by the Protection of the Sea (Prevention of Pollution from Ships) Act 1983). Additionally, the survey vessels may have to discharge bilge water and deck drainage during the survey if required. There are no predicted long-term effects at a population level on any species identified in this EP, and no adverse effects on the environmental values of protected areas or KEFs as a result of routine permissible waste discharges are expected. Based on the discussions above, including the potential impacts on the environment and the associated control measures to be implemented, the residual risk from routine permissible waste discharges from the survey vessels is considered **Negligible** and to **ALARP**. Therefore, the impacts from this activity associated with the Otway Basin 3D MC MSS are considered to be at an **Acceptable Level**.

Acceptability Statement
Impacts and risks classified as 'Type A' or above are considered acceptable if the requirements in **Table 51** can be demonstrated and if the level of residual impact and risk are determined to be Moderate or less. Based on the above evaluation, the potential impacts from routine permissible waste discharges meets the requirements of the impact and risk acceptability criteria. The control measures that will be implemented throughout the Otway Basin 3D MC MSS have been developed in accordance with these criteria and are considered appropriate to manage the impacts of routine permissible waste discharges on all identified receptors to an **Acceptable Level.**

7.3.6 Environmental Performance

Table 92 Environmental Performance Outcomes, Standards and Measurement Criteria for Routine Permissible Waste Discharges

Number	Environmental Performance Outcome	Environmental Performance Standard
EPO 19	No release of unplanned objects, emissions or discharges to sea or air	**EPS 165** to **EPS 185**
EPO 20	All routine permissible waste discharges will meet or exceed the requirements of MARPOL Annex I, IV, V and Marine Orders 91, 95 and 96	**EPS 165** to **EPS 185**

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
The Otway Basin 3D MC MSS will be undertaken in accordance with the approved EP.	**EPS 165**: The Otway Basin 3D MC MSS may only commence following acceptance of the EP by NOPSEMA.	Pre-mobilisation audit and inspection are completed prior to operations and confirm an accepted EP has been obtained. Audit records verify compliance with the requirements of the EP.	TGS VOM EA
	EPS 166: The Seismic Survey will be undertaken in accordance with the accepted EP.	Bridge logs verify compliance with the requirements of the EP. Audit records verify compliance with the requirements of the EP.	TGS VOM VOC EA Vessel Master SEA
All survey vessels will comply with the requirements of MARPOL Annex I (Regulations for the Prevention of Pollution by Oil), Marine Order 91 (Marine Pollution Prevention – Oil) and *Protection of the Sea* (Prevention of Pollution from Ships) *Act 1983,* including*:* In accordance with MARPOL Annex I and Marine Order 91, vessels ≥ 400 gross tonnes will: • Have an oil discharge monitoring and control system and oil filtering equipment on-board. • The oil discharge monitoring and control system will be maintained and operated to the 15 ppm standard. • Hold a current IOPP Certificate. • Maintain and oil usage management logbook. • Treated bilge water will only be discharged when the vessel is moving and the oil discharge monitoring and control system and oil filtering equipment is operating. If oil discharge monitoring and control system and oil filtering equipment is unavailable, bilge water mixtures will be retained onboard for onshore disposal.	**EPS 167**: An IOPP Certificate will be held by every ship of 400 gross tonnage and above involved in the Otway Basin 3D MC MSS as per division 3 of Marine Order 91, and MARPOL Annex I.	A pre-mobilisation vessel audit and inspection confirms IOPP Certificate is valid.	TGS VOM VOC Vessel Master Party Chief
	EPS 168: Oil filtering equipment (of an approved design) processes oily water to meet the 15 ppm requirement of MARPOL Annex I, Marine Order 91 and the PSPPS Act. Any discharge of processed oily water will be undertaken while the vessel is underway in accordance with the above concentration requirements. Any separated oil will be retained/stored onboard and transported to shore for disposal at an approved facility.	Pre-mobilisation vessel audit and inspection confirms approved oil filtering equipment is onboard and equipment is operational. Discharge logs confirm that any discharges of processed oily water are compliant with MARPOL Annex I, Marine Order 91 and the PSPPS Act.	Party Chief Chief Engineer Survey Vessel SEA CSR Vessel Master
All survey vessels will comply with the requirements of MARPOL Annex IV (Regulations for the Prevention of Pollution by Sewage from Ships) and Marine Order 96 (Marine Pollution Prevention – Sewage), including:	**EPS 169**: An ISPP Certificate will be held by every ship of 400 gross tonnage and above involved in the Otway Basin 3D MC MSS, and any vessel certified to carry more than 15 persons as per division 3 of Marine Order 96, and Regulation 4 of MARPOL Annex IV.	A pre-mobilisation vessel audit and inspection confirms ISPP Certificate is valid.	Vessel Master VOC Party Chief SEA

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
• A valid ISPP Certificate, as required by vessel class; • Sewage will only be discharged via an IMO-approved sewage treatment plant; or • Comminuted/disinfected sewage via an IMO-approved system will only be discharged when ≥3 NM from land and when the vessel is moving at ≥4 knots; or • Sewage that has not been comminuted/disinfected via an IMO-approved system will only be discharged when ≥12 NM from land and when the vessel is moving at ≥4 knots.	**EPS 170**: When sewage is comminuted and disinfected using an approved system (as per Marine Order 96), the discharge to sea will only occur at a moderate rate when the vessel is travelling at greater than 4 knots, and when further than 3 NM from the nearest land as per MARPOL Annex IV.	Pre-mobilisation vessel audit and inspection confirms approved sewage comminuter and disinfection system is onboard and equipment is operational. Discharge logs confirm that any discharges of processed sewage are compliant with MARPOL Annex IV and Marine Order 96.	Party Chief Chief Engineer Survey Vessel SEA CSR Vessel Master
	EPS 171: When sewage is not comminuted or disinfected using an approved system, the discharge to sea will only occur at a moderate rate when the vessel is travelling at greater than 4 knots, and when further than 12 NM from the nearest land as per MARPOL Annex IV.	Discharge logs confirm that any discharges of unprocessed sewage are compliant with MARPOL Annex IV and Marine Order 96.	Party Chief Chief Engineer Survey Vessel SEA CSR Vessel Master
	EPS 172: When operating vessels within 12 NM of the coast, any sewage that is not comminuted or disinfected through an approved system will be stored within holding tanks. This sewage will then either: be transferred ashore for appropriate treatment; or, discharged to sea once further than 12 NM from the coast as per the standards above.	Where they occur, discharge logs confirm that any discharges of processed sewage are compliant with MARPOL Annex IV and Marine Order 96. Where waste is stored for onshore disposal, Waste Transfer Certificate issued by licensed facility or carrier are obtained and records kept on file in accordance with record management procedures.	Party Chief Chief Engineer Survey Vessel SEA CSR Vessel Master
All survey vessels will comply with the requirements of MARPOL Annex V (Regulations for the Prevention of Pollution by Garbage from Ships) and Marine Order 95 (Marine Pollution Prevention - Garbage), including: • Putrescible waste will be discharged while the vessel is moving and ≥12 NM from the nearest land; or • Putrescible waste will pass through a comminuter or grinder capable of passing through a screen with no opening wider than 25 mm in diameter prior to discharge and discharged while the vessel is moving and ≥3 NM from the nearest land.	**EPS 173**: When food wastes have been comminuted or ground down to less than 25 mm, the discharge of this waste can occur when further than 3 NM from the nearest land as per MARPOL Annex V.	Pre-mobilisation vessel audit and inspection records confirm that macerator is onboard, functional and in use. Discharge logs confirm that any discharges of processed food wastes are compliant with MARPOL Annex V and Marine Order 95.	Party Chief Chief Engineer Survey Vessel SEA CSR Vessel Master
	EPS 174: When food wastes have not been comminuted or ground down to less than 25 mm, the discharge of this waste can occur when further than 12 NM from the nearest land as per MARPOL Annex V.	Discharge logs confirm that any discharges of unprocessed food wastes are compliant with MARPOL Annex V and Marine Order 95.	Party Chief Chief Engineer Survey Vessel SEA CSR Vessel Master
	EPS 175: Any vessel used for the Seismic Survey over 100 gross tonnes or certified to carry 15 or more persons will hold and maintain a Garbage Management Plan for minimising, collecting, storing, processing and disposing of garbage, including the use of equipment on board, as per MARPOL Annex V and Marine Order 95.	A pre-mobilisation vessel audit and inspection confirms a valid Garbage Management Plan is in place, in accordance with MARPOL Annex V and Marine Order 95.	VOC Vessel Master Party Chief
	EPS 176: All permissible waste discharges will be recorded within the vessel's discharge log.	Discharge logs confirm that any planned discharges of processed and unprocessed oil, sewage and waste have been recorded.	Vessel Master Party Chief Chief Engineer Survey Vessel SEA CSR
Equipment/machinery involved in the treatment of wastes, such as oil discharge monitoring and control systems, oil filters and communiters, will be maintained and calibrated, as per the manufacturers guidelines, to ensure they operate effectively.	**EPS 177**: Equipment/machinery involved in the treatment of wastes, such as oil discharge monitoring and control systems, oil filters and communiters, will be maintained and calibrated, as per the manufacturers guidelines, to ensure they operate effectively.	Maintenance logs confirm appropriate maintenance. A pre-survey vessel audit and inspection confirms that equipment involved in the treatment of wastes has undergone appropriate maintenance.	Party Chief Chief Engineer Survey Vessel SEA CSR

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
Equipment/machinery involved in the treatment of wastes will be operated by trained crew who will be instructed at the pre-survey environmental induction on how to comply with the requirements of this EP.	**EPS 178**: Equipment/machinery involved in the treatment of wastes will be operated by trained crew who will be instructed at the pre-survey environmental induction on how to comply with the requirements of this EP. 	EPS 181: Spill response kits will be stored nearby the storage location of hazardous substances to support effective clean-up if a spill does occur.	A pre-mobilisation vessel audit and inspection confirms the availability and location of spill response kits.	Party Chief SEA CSR Vessel Master
Deck scupper plugs will be available beside all deck drainage points that lead overboard.	**EPS 182**: Scupper plugs, or equivalent drainage control measures, will be readily available to allow drains to be blocked in the event of a hydrocarbon or cleaning chemicals spill to deck (i.e. outside bunded area).	A pre-mobilisation vessel audit and inspection confirms the availability and location of scupper plugs.	Party Chief SEA CSR Vessel Master
Display of signage notifying vessel crew of disposal requirements.	**EPS 183**: Display of signage notifying vessel crew of disposal requirements.	A pre-mobilisation vessel audit and inspection confirms signage consistent with the requirements of this EP has been developed.	Party Chief SEA CSR Vessel Master
There will be no planned discharge of routine permissible wastes within the boundaries of the Nelson AMP or Zeehan AMP.	**EPS 184**: Planned routine permissible discharges will not occur within the boundaries of the Nelson AMP and Zeehan AMP.	Discharge logs confirm that discharges have not occurred within the boundaries of Australian Marine Parks.	Party Chief SEA CSR Vessel Master
	EPS 185: Shape files will be loaded onto the survey vessels' navigation system outlining exclusion areas around the Nelson AMP and Zeehan AMP within which permissible wastes cannot be discharged.	Discharge logs confirm that discharges have occurred outside of the boundaries of the Nelson AMP and Zeehan AMP. Vessel track records. Exclusion polygons on survey vessel's navigation system.	SEA CSR Vessel Master

7.3.7 Routine Permissible Waste Discharge Impact and Risk Summary

Based on the assessment above, including the identification of potential impacts on the environment and the associated control measures to be implemented, the residual risk of routine permissible waste discharges during the Otway Basin 3D MC MSS is considered to be **Negligible**.

The suite of control measures to be implemented have been developed in accordance with Industry Best Practice and relevant legislation. Consequently, it is considered that the environmental impacts and risks on the marine environment and receptors arising from routine permissible waste discharges are reduced to **ALARP**.

In accordance with the acceptability requirements prescribed in **Section 6.4**, the suite of control measures are considered appropriate to manage the risks and impacts arising from routine permissible waste discharges during the Otway Basin 3D MC MSS on all receptors to an **Acceptable Level**.

7.4 Atmospheric Emissions

7.4.1 Description of Source of the Impact and Risk

The release of combustion of exhaust gases from mechanical equipment (engines, generators, winches, power-units, plant machinery etc.) and the incineration of wastes represent the main sources of potential atmospheric emissions during the Otway Basin 3D MC MSS. Most of these gaseous emissions will be in the form of carbon dioxide (**CO_2**) and carbon monoxide (**CO**); however, smaller quantities of other gases such as methane (**CH_4**), nitric oxide (**NO**), nitrogen dioxide (**NO_2**) and sulphur dioxide (**SO_2**) may be emitted particularly during any incomplete combustion. Fine particulate matter (**$PM_{2.5}$**) may also be emitted from the combustion of MDO (Nabi *et al*., 2012).

Vessels used during the Otway Basin 3D MC MSS may have Ozone Depleting Substances (**ODS**) onboard. However, if these ODSs are onboard the vessel, they will be within closed loop systems, such as rechargeable refrigeration systems, and will not be discharged deliberately.

7.4.2 Evaluation of Known and Potential Impacts and Risks to Environmental Receptors

Using the information presented in **Section 4** to **Section 5**, the impact and risk assessment has been undertaken for those receptors determined to be relevant to the activity as listed in **Table 93.**

Table 93 Environmental Receptors Assessed

Receptor	Section reference
Marine Environmental Quality	**Section 7.4.2**
Seabirds	

A reduction in ambient air quality is known to contribute to human health issues, such as pulmonary disease, cardiovascular disease and cancer (Steiner *et al*., 2016). Atmospheric emissions from the survey vessels, onboard equipment and incineration of wastes can cause a reduction in air quality in the localised area around the vessels, however, the emissions will be rapidly dispersed by strong winds that typify the area resulting in any localised pollution in the vicinity of the discharges being short lived. The open ocean nature of the OA and the variable, moderate wind conditions will ensure that emissions from the vessels will not impact on the onshore/nearshore interests/communities. Greenhouse gas emissions (CO_2 and CH_4) are linked to climate change.

The volume of the emissions associated with this Otway Basin 3D MC MSS will centre around the vessels and be relatively small in terms of the wider environment (which could be up to 32 m^3 per day of fuel usage as per **Section 3.5.4**). In addition, the constant movement of the vessels will ensure that the discharge is not occurring in a single location for any significant period of time.

Potential receptors therefore include seabirds and migratory shorebirds which may traverse the OA whilst foraging or on route between staging sites and foraging grounds, and humans in the immediate vicinity of the vessel during discharge events. Air pollution is not considered a substantial threat to seabird species, with avian species in close proximity to urban and industrial areas most at risk from poor air quality (Richards *et al*., 2021).

The main control measures (detailed below in **Section 7.4.4**) relate to the compliance with MARPOL Annex VI, and the use of MDO instead of Heavy Fuel Oil (**HFO**). It is considered that the consequence of this activity occurring is *Negligible*, with the likelihood of this consequence occurring being *Likely*. This results in a residual risk of **Negligible**.

7.4.3 Decision Context

The decision context for atmospheric emissions has been assessed as Type A for all receptors, given the predicted impacts and risks are well understood and uncertainty is minimal, with little or no interest from relevant persons.

7.4.4 Identification of Control Measures, Residual Risk Assessment and Demonstration of ALARP

A Hierarchy of Controls methodology (**Table 94**) has been used to assess control measures to determine the benefits in their use towards risk reduction. The control measures that will be implemented during the Otway Basin 3D MC MSS to manage the impacts from atmospheric emissions to **ALARP** are included in **Table 95**. The control measures that will be adopted are those that have been assessed and characterised as effective and practicable to implement.

Table 94 Hierarchy of Control Measures for Atmospheric Emissions

Eliminate	Fuel use and its associated atmospheric emissions cannot be eliminated as fuel is a fundamental requirement for the operation of the survey vessels. Deliberate discharge of ODS will be eliminated during the Otway Basin 3D MC MSS as outlined in **Table 95**.
Substitute	As outlined within **Table 95**, the survey vessels will use MDO to power their engines, rather than other fuels such as HFO. Although the cost of using MDO is higher than that of HFO, the reduction in sulphur content is considered an important step in managing impacts to **ALARP**. No other alternative fuel sources are currently commercially viable for larger vessels.
Reduce	Similar to the discussion around substitution above, the use of MDO will reduce the contaminants discharged from the combustion engines on the vessels in order to meet the requirements of Marine Order 97, the PSPPS Act and MARPOL Annex VI.
Mitigate	The control measures within **Table 95** have been assessed to ensure that they mitigate the impacts from atmospheric emissions to **ALARP**. This is primarily done through the implementation of measures required under Marine Order 97, the PSPPS Act and MARPOL Annex VI.

Table 95 Assessment of Control Measures for Atmospheric Emissions

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Legislative Requirements:			
The Otway Basin 3D MC MSS will be undertaken in accordance with the approved EP.	P = Yes E = Effective	All survey vessels undertaking an offshore activity in waters between 3 and 200 NM must undertake that activity in line with an approved EP. The approved EP outlines the measures that will be taken to ensure that environmental effects from the activity will be reduced to **ALARP** and **Acceptable Levels**, including the management of atmospheric emissions.	Yes
Compliance with: MARPOL Annex VI (Regulations for the Prevention of Air Pollution from Ships). Protection of the Sea (Prevention of Pollution from Ships) Act 1983. Marine Order 97 (Air Pollution): • Vessels >400 tonnes require a certificate to demonstrate that they comply with the requirement to prevent unnecessary air pollution; • The vessel engines do not emit excess NOx emissions; • Incinerators used are of an approved standard and it is operated correctly; • Vessels must comply with a plan for energy efficiency and implement a Ship Energy Efficiency Management Plan (**SEEMP**); • Vessels shall not emit excess sulphur emissions; • Noxious and toxic substances shall not be emitted through combustion of illegal substances; and • ODS shall not be deliberately released.	P = Yes E = Effective	MARPOL is a legislative requirement for vessels operating in Australian Commonwealth waters and will be implemented by all vessels. Implementation of the regulations will reduce the atmospheric emissions released into the environment. It is a legislative requirement to meet the relevant aspects of MARPOL Annex VI, the PSPPS Act and Marine Order 97.	Yes
Good Industry Practice			
Vessels will use MDO grade fuel during the survey. The sulphur content of fuel oil used on board vessels for propulsion or operation will not exceed 0.50% m/m.	P = Yes E = Effective	The vessels associated with the Otway Basin 3D MC MSS will be utilising MDO grade fuel in order to reduce the pollutants from the combustion engines. As of 1 January 2020, the new limit for sulphur in fuel oil used on-board vessels is 0.50% m/m. MDO usually has less than 0.2% sulphur which aids in meeting the requirements of the legislation outlined in the control measure above. Good industry practice, environmental benefit outweighs additional cost.	Yes
Fuel consumption will be recorded and monitored for abnormal consumption, with corrective action taken if necessary.	P = Yes E = Effective	While fuel consumption throughout the Otway Basin 3D MC MSS is inevitable, abnormal consumption results in additional atmospheric emissions as well as additional costs. Good industry practice, environmental benefit outweighs additional cost.	Yes
All combustion and incineration machinery will be appropriately maintained as per the manufacturer's guidelines.	P = Yes E = Effective	Routine maintenance ensures that machinery is running in accordance with the manufacturer's specifications, reducing excess emissions. Good industry practice, environmental benefit outweighs additional cost.	Yes
Only wastes approved by the vessel's Garbage Management Plan will be incinerated and no oil or other noxious substances will be incinerated.	P = Yes E = Effective	Incineration of materials not approved by the Garbage Management Plan may lead to the release of toxic emissions and will not be compliant with MARPOL. Good industry practice, environmental benefit outweighs additional cost.	Yes
Incineration will only occur when the vessel is a distance greater than 12 NM from shore.	P = Yes E = Effective	Incineration of wastes beyond 12 NM from shore will not result in any emissions that will make their way to shore, nor will any emissions be visible from shore. Good industry practice, environmental benefit outweighs additional cost.	Yes

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Alternatives/**Substitutes Controls Considered:**			
No incineration on vessels.	P = No E = Effective	Incineration of wastes on vessels is a standard industry practice and negates the need for additional visits from supply vessels to remove waste. The storage of wastes onboard the survey vessels have added risks to human health.	No
Use of alternative fuels to power vessels.	P = No E = Effective	Alternative fuel sources include solar, wind, and biofuels. Adopting renewable energy sources would incur considerable cost associated with vessel modifications. Such fuel sources have not been commercially proven for vessels and helicopters such as those that will be used during the Otway Basin 3D MC MSS.. Given the low-level of risk identified, this option is not considered commercially viable. Non-fuel powered engines are not considered technically efficient to execute.	No
Use of incinerators and engines with higher environmental efficiency.	P = No E = Effective	There are significant costs associated with modifying vessel equipment such as incinerators and engines. The costs are grossly disproportionate to the low environmental benefit gained from limited improvements in air quality that may result.	No
Transferring non-hazardous combustible waste to shore for disposal.	P = No E = Effective	If waste were not incinerated offshore, additional cost, safety and environmental implications would be incurred associated with transferring non-hazardous combustible waste to shore for disposal. This would also be unlikely to reduce overall emissions as additional supply vessel visit would be required to collect and transfer the waste to shore, where it would then need to be dealt with.	No
Additional Controls Considered:			
Non-essential machinery will be routinely shut-down on survey vessels.	P = Yes E = Limited	Due to the limited benefit gained from shutting-down non-essential machinery, and the limited risk associated with atmospheric emissions, this control was determined to be unnecessary.	No
Eliminate atmospheric emissions during operation.	P = No E = Effective	Vessels are required for the Otway Basin 3D MC MSS to collect data. Without vessels, the survey would not be able to occur.	No
Residual Risk of Impact (Receptor)	**Consequence**	**Likelihood**	**Residual Risk Ranking**
Marine Environmental Quality	Negligible	Likely	**Negligible**
Seabirds	Negligible	Likely	**Negligible**
ALARP Statement			
The decision context has been assessed as Type A and the overall residual risk has been determined to be Negligible. TGS considers the adopted control measures are appropriate to manage the impacts of atmospheric emissions during the Otway Basin 3D MC MSS. The proposed control measures have been developed in accordance with the legislative requirements and good industry practice and take into account the specific environmental, social, economic and cultural characteristics of the OA. No effective and practicable alternative or additional control measures were identified as part of the assessment process. Therefore, the predicted impacts to receptors from Atmospheric Emissions are reduced to **ALARP.**			

7.4.5 Impact and Risk Acceptability

Table 96 Demonstration of General Impact and Risk Acceptability for Atmospheric Emissions

Criteria for Acceptance	Acceptability Summary
Residual Risk Ranking	The Residual Risk has been determined to be Negligible.
Ecologically Sustainable Development	The management of the impacts and risks associated with atmospheric emissions proposed by TGS can be carried out in compliance with the five principles of ESD as defined within the EPBC Act. These principles have been considered as part of the development of this EP and risk assessment process. The assessment has not identified any adverse impacts to the principles of ESD, with no threats of serious or irreversible damage, no impacts to biological diversity and ecological integrity, no degradation of inter-generational equity, or negative effects on the social and economic integrity in the short or long-term.
TGS's Internal Context	The proposed management of the risks associated with the establishment of IMS is consistent with TGSs QHSE Policy commitments of: • Protecting the environment; and • Conducting operations in an environmentally sustainable and responsible manner.
Existing Environmental Context	Based on the proposed control measures to be implemented, it is considered that atmospheric emissions will not result in a significant impact on environmental values or sensitivities within the OA, including seabird species and migratory shorebirds which may traverse the OA and be temporarily exposed to atmospheric emissions. It is considered that the proposed control measures provide appropriate protection to marine fauna and other marine users from the potential effects associated with atmospheric emissions. A number of control measures were considered as part of the assessment process, and it was concluded that the addition of any further control measures not already considered would provide little or no additional protection.
External Context – Management Plans, Species Recovery Plans and Conservation Advice	The residual risk of the atmospheric emissions has been determined to be Negligible and will not have a significant impact on a matter of national environmental significance in accordance with EPBC Act Policy Statement 1.1. **<u>Draft Wildlife Conservation Plan for Seabirds</u>** Point source atmospheric emissions as a result of the Otway Basin 3D MC MSS are predicted to cause negligible effects to seabirds which may traverse the OA. The Draft Wildlife Conservation Plan for Seabirds does not identify, short-term, point source atmospheric emissions as a threat to seabird populations. The activity is, therefore, considered consistent with the objective of facilitating conservation of seabird populations. Consideration to the effects of chronic atmospheric emissions will be achieved through the implementation of the SEEMP. **<u>AMP Values, Management Prescriptions and IUCN Reserve Management Principles</u>** The management prescriptions for AMPs do not include information on atmospheric emissions from commercial vessels. **<u>Conservation values and objectives of the South-east Commonwealth Marine Reserves Network Management Plan 2013 – 2023</u>** Atmospheric emissions are not expected to impact significantly on the environmental values or sensitivities of the South-east Marine Region at a local or regional level.
Social Acceptance – Relevant Person Expectations	During consultation with relevant persons no concerns were raised in regard to possible impacts from atmospheric emissions, and as such no additional control/mitigation measures were expected or put in place as a result. Consequently, the environmental impacts relating to atmospheric emissions from the survey vessels were considered to be at a socially **Acceptable Level**.
External Context – Commonwealth and State Legislative Criteria	TGS will ensure the Otway Basin 3D MC MSS air emissions will comply with the relevant legislative requirements and applicable international conventions, including: • MARPOL 73/78 Annex VI Prevention of Air Pollution by Ships; • PSPPS Act, 1983 (Part IIID Prevention of Air Pollution); • Maritime Legislation Amendment (Prevention of Air Pollution from Ships) Act 2007; • Marine Orders Part 97 (Marine Pollution Prevention – air pollution); • Marine Notice 11/2015 Measure to Reduce Greenhouse Gas Emissions from International Shipping; and • Marine Notice 05/2017 Regulations for Air Emissions from Ships.

Criteria for Acceptance	Acceptability Summary
Industry Best Practice	The control measures are based on industry best practice and best practice guidelines, including: • The IAGC Environmental Manual for Worldwide Geophysical Operations which provides guidance on engine emissions, including: • Ensuring vessels are fitted with appropriate emission monitoring and control systems to meet applicable flag state and vessel design class requirements; • Servicing of exhaust systems occurs on a regular basis to ensure that noise and emissions are kept to appropriate levels (no unburned fuels and exhaust gases to create localised pollution); • Require low-sulphur MDO; and • The APPEA Code of Environmental Practice includes an objective to reduce greenhouse gas emissions to an **Acceptable Level** and reduce the risk of impacts to **ALARP**.
ALARP	Total elimination of all impacts associated with atmospheric emissions cannot be achieved, as engines must be used onboard the vessel and there are no practicable alternatives. Following the implementation of the control measures the potential impacts to the environment from atmospheric emissions are likely to be localised in nature and short-term given the relative spatial extent of the vessel's trajectory across the total OA and the duration of the Otway Basin 3D MC MSS. Based on the discussions within the EP, including the potential impacts on the environment and the associated control measures to be implemented, the residual risk from atmospheric emissions from the survey vessels is considered **Negligible** and to **ALARP**. Therefore, the impacts and residual risk from this activity associated with the Otway Basin 3D MC MSS are considered to be at an **Acceptable Level**.

Acceptability Statement
Impacts and risks classified as 'Type A' or above are considered acceptable if the requirements in **Table 51** can be demonstrated and if the level of residual impact and risk are determined to be Moderate or less. Based on the above evaluation, the potential impacts from atmospheric emissions meets the requirements of the impact and risk acceptability criteria. The control measures that will be implemented throughout the Otway Basin 3D MC MSS have been developed in accordance with these criteria and are considered appropriate to manage the impacts of atmospheric emissions on all identified receptors to an **Acceptable Level.**

7.4.6 Environmental Performance

Table 97 Environmental Performance Outcomes, Standards and Measurement Criteria for Atmospheric Emissions

Number	Environmental Performance Outcome	Environmental Performance Standard
EPO 21	No release of unplanned objects, emissions or discharges to sea or air	**EPS 186** to **EPS 198**
EPO 22	All unplanned atmospheric emissions produced during the survey (including NO_X, SO_X, CO, CO_2, CH_4 and particulates) meet or exceed the requirements MARPOL Annex VI and Marine Order 97.	**EPS 186** to **EPS 198**

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
The Otway Basin 3D MC MSS will be undertaken in accordance with the approved EP.	**EPS 186**: The Otway Basin 3D MC MSS may only commence following acceptance of the EP by NOPSEMA.	Pre-mobilisation audit and inspection are completed prior to operations and confirm an accepted EP has been obtained. Audit records verify compliance with the requirements of the EP.	TGS VOM EA
	EPS 187: The Otway Basin 3D MC MSS will be undertaken in accordance with the accepted EP.	Bridge logs verify compliance with the requirements of the EP. Audit records verify compliance with the requirements of the EP.	TGS VOM VOC EA Vessel Master SEA
Compliance with: MARPOL Annex VI (Regulations for the Prevention of Air Pollution from Ships). Protection of the Sea (Prevention of Pollution from Ships) Act 1983. Marine Order 97 (Air Pollution): • Vessels >400 tonnes require a certificate to demonstrate that they comply with the requirement to prevent unnecessary air pollution; • The vessel engines do not emit excess NOx emissions; • Incinerators used are of an approved standard and it is operated correctly; • Vessels must comply with a plan for energy efficiency and implement a SEEMP; • Vessels shall not emit excess sulphur emissions; • Noxious and toxic substances shall not be emitted through combustion of illegal substances; and • ODS shall not be deliberately released.	**EPS 188**: All vessels used in the Otway Basin 3D MC MSS over 400 gross tonnage will hold an International Air Pollution Prevention Certificate (**IAPP Certificate**) as per the requirements of Marine Order 97 and MARPOL Annex VI.	A pre-mobilisation vessel audit and inspection confirms IAPP Certificate is valid.	VOC Vessel Master Party Chief SEA CSR
	EPS 189: The engines in the vessels used for the Otway Basin 3D MC MSS will meet the prescribed NOx emission levels set within Marine Order 97 and MARPOL Annex VI.	A pre- mobilisation vessel audit and inspection confirms the vessel engines meet the specifications required to operate in accordance with the Marine Order 97 and MARPOL Annex VI.	TGS VOM EA Vessel Master
	EPS 190: The SOx content of the fuel used within the survey vessels will not exceed the limits set within Marine Order 97, the PSPSS Act and MARPOL Annex VI.	Fuel data sheet confirms low sulphur content. A pre-mobilisation vessel audit and inspection confirms the SOx content of fuel used within the survey vessels is compliant with Marine Order 97, the PSPSS Act and MARPOL Annex VI.	TGS VOM VOC EA Vessel Master SEA
	EPS 191: All vessels used during the Otway Basin 3D MC MSS over 400 gross tonnage will have, and comply with, a SEEMP as per Marine Order 97 and MARPOL Annex VI.	A pre-mobilisation vessel audit and inspection confirms a SEEMP is in place. Monitoring in accordance with the SEEMP demonstrates compliance with the SEEMP. Bridge logs demonstrate compliance with the SEEMP.	TGS VOM EA Vessel Master
	EPS 192: Any Incineration onboard the vessels will be undertaken in accordance with Marine Order 97 and MARPOL Annex VI, including the prohibition of incinerating noxious and hazardous substances.	Incineration Logs demonstrate compliance with Marine Order 97 and MARPOL Annex VI	Party Chief SEA CSR Vessel Master

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
	EPS 193: An ODS Record Book will be maintained if the Seismic Vessel has a rechargeable system that contains ODS as per the PSPPS Act and confirms no planned ODS discharges have occurred.	Where required, A pre-survey vessel audit and inspection confirms an ODS Record Book is available and confirms no planned ODS discharges have occurred.	Party Chief SEA CSR Vessel Master
Vessels will use MDO grade fuel during the survey. The sulphur content of fuel oil used on board vessels for propulsion or operation will not exceed 0.50% m/m.	**EPS 194**: MDO is the primary fuel for vessels associated with the Otway Basin 3D MC MSS. The sulphur content of fuel oil used on board vessels for propulsion or operation will not exceed 0.50% m/m.	The Bunker Note confirms MDO is the primary fuel for use within survey vessels. Oil usage records show MDO fuel is used.	Party Chief SEA CSR Vessel Master
Fuel consumption will be recorded and monitored for abnormal consumption, with corrective action taken if necessary.	**EPS 195**: Fuel use will be recorded and monitored for excessive fuel consumption, with corrective action taken if necessary.	Bridge log confirms fuel use is consistent with the SEEMP. Where excessive fuel consumption is identified, records show the processes for Management of Non-Conformances are followed.	Party Chief SEA CSR Vessel Master
All combustion and incineration machinery will be appropriately maintained as per the manufacturer's guidelines.	**EPS 196**: All combustion and incineration machinery will be appropriately maintained as per the manufacturer's guidelines.	Maintenance logs confirm appropriate maintenance. A pre-mobilisation vessel audit and inspection confirms that combustion and incineration machinery has undergone appropriate maintenance.	Party Chief SEA CSR Vessel Master
Only wastes approved by the vessel's Garbage Management Plan will be incinerated and no oil or other noxious substances will be incinerated.	**EPS 197**: Only wastes approved by the vessel's Garbage Management Plan will be incinerated and no oil or other noxious substances will be incinerated.	Incineration Log demonstrate compliance with the Garbage Management Plan.	Party Chief SEA CSR Vessel Master
Incineration will only occur when the vessel is a distance greater than 12 NM from shore.	**EPS 198**: Incineration will only occur when the vessel is a distance greater than 12 NM from shore.	Incineration Logs (and where required AIS tracking data) demonstrate compliance.	Party Chief SEA CSR Vessel Master

7.4.7 Atmospheric Emissions Impact and Risk Summary

Based on the discussions above, including the potential impacts on the environment and the associated control measures to be implemented, the residual risk from atmospheric emissions generated from the survey vessels and on-board waste incineration is considered **Negligible.**

The suite of control measures to be implemented have been developed in accordance with Industry Best Practice and relevant legislation. Consequently, it is considered that the environmental impacts and risks on the marine environment and receptors arising from atmospheric emissions are reduced to **ALARP**.

In accordance with the acceptability requirements prescribed in **Section 6.4**, the suite of control measures are considered appropriate to manage the risks and impacts arising from atmospheric emissions during the Otway Basin 3D MC MSS on all receptors to an **Acceptable Level**.

7.5 Artificial Light Emissions

7.5.1 Description of Source of the Impact and Risk

Artificial lighting is required on the survey vessels for the health and safety of crew onboard (e.g. deck lighting for night operations) and for safe navigation of vessels underway at sea at night and in poor weather conditions. Different navigation lights are required specific to that particular vessel and size, as well as whether the vessel is engaged in towing and restricted in its ability to manoeuvre.

The primary sources of artificial lighting in the offshore marine environment during the Otway Basin 3D MC MSS will result from the deck and navigational lights onboard the survey vessels. Deck areas need to be lit at all times for personnel safety, with deck lighting typically consisting of bright white lights focused on working areas. Spot lighting may be required for in-sea inspection, deployment, and retrieval of survey equipment. Navigational lights are typically elevated on the vessel, outwards facing, and of lesser intensity than deck lighting.

7.5.2 Evaluation of Known and Potential Impacts and Risks to Environmental Receptors

Using the information presented in **Section 4** to **Section 5**, the impact and risk assessment has been undertaken for those receptors determined to be relevant to the activity as listed in **Table 98**.

Table 98 Environmental Receptors Assessed

Receptor	Section reference
Fish, Sharks, Rays	**Section 7.5.2.1**
Marine Mammals	**Section 7.5.2.2**
Marine Reptiles	**Section 7.5.2.3**
Seabirds	**Section 7.5.2.4**

Artificial light at night (**ALAN**) is a recently acknowledged form of anthropogenic pollution which is rapidly expanding in the marine environment (Davies *et al.,* 2014; Gaston *et al.,* 2021; Tidau *et al*., 2021). ALAN affects marine organisms as it introduces light in places, times and at intensities which it does not naturally occur, and is introducing light with a spectrum that is different from that of natural sources (i.e. sunlight, moonlight or starlight) (Gaston *et al*., 2015). Artificial light can disrupt critical behaviour (e.g. migrations) and cause physiological changes in wildlife, potentially stalling the recovery of a threatened species (Commonwealth of Australia, 2020). Disorientation and behaviour modifications are the two main modes through which ALAN is known to affect marine fauna and are the focus of this EP; however physiological changes are discussed for fish and benthic communities.

Artificial lighting on vessels at sea can attract and disorientate marine animals and affect their physiology (Davies *et al.,* 2014; Poot *et al*., 2008). The effects of ALAN can be particularly high for juvenile animals such as turtles and fledgling seabirds/novice flyers in coastal locations (Telfer *et al*., 1987), and ALAN has been linked to an increased risk of bird collision with vessels (particularly their rigging) (Black, 2005). Procellariiformes (comprising albatrosses, shearwaters, fulmars, prions, large petrels, storm petrels, and diving petrels) are particularly at risk as they are known to aggregate around anthropogenic light sources, with fledging and migratory times particularly vulnerable times for these birds (Le Corre *et al*, 2002; Miles *et al*, 2010; Gjerdrum *et al*., 2021). Several species of Procellariiformes have been identified as present within the OA.

The combination of colour, intensity, closeness, direction, and persistence of light source are key factors in determining the magnitude of environmental impacts (WA EPA, 2010; Commonwealth of Australia, 2020). For example, artificial lights that are fixed or stationary in the marine environment have been shown to attract aggregations of zooplankton and then baitfish and/or squid, which are prey for higher trophic order species that take advantage of these aggregations for feeding (Golder, 2007). Increased amounts of light at night in the marine environment can also possibly be detrimental to marine mammals by allowing predators to see the mammals more easily during normally dark night times.

The potential adverse impacts on marine fauna associated with ALAN is well understood, as is reflected in the development of Commonwealth guidelines designed to mitigate the effects from these activities (Commonwealth of Australia 2020). The National Light Pollution Guidelines for Wildlife recommends using Best Practice Lighting Design to reduce light pollution and minimise the effect on wildlife and undertaking an ERA for effects on listed species for which artificial light has been demonstrated to affect behaviour, survivorship or reproduction, and where there is important habitat within 20 km of a project (Commonwealth of Australia, 2020).

According to the National Light Pollution Guidelines for Wildlife (Commonwealth of Australia, 2020), a 20 km distance threshold provides a precautionary limit based on observed effects of sky glow on marine turtle hatchlings demonstrated to occur at 15 – 18 km and grounding behaviour of fledgling seabirds in response to artificial light 15 km away. Although, the effect of light glow may occur at distances greater than 20 m for some species and under certain environmental conditions (Commonwealth of Australia, 2020).

Potential receptors therefore include fish, sharks and rays, marine turtles, seabirds and migratory shorebirds. As cetaceans predominantly utilise acoustic senses to monitor and navigate their environment, impacts are considered to be unlikely. However, an assessment of potential impacts to marine mammals has been undertaken in **Section 7.5.2.2**, below.

7.5.2.1 Bony Fish and Elasmobranchs

The response of fish to artificial light varies according to species and habitat; for example, it can throw off fine-tuned nocturnal behaviours such as navigation, hunting patterns or the ability to forage while evading predators (Milicich *et al*., 1992; Meekan *et al*., 2001). Lindquist *et al*. (2005) concluded from a study that artificial lighting associated with offshore oil and gas activities resulted in an increased abundance of clupeids (herring and sardines) and engraulids (anchovies) around lighted structures; these species are known to be highly photopositive. Attraction of fish to light may result in an increase in predation from larger fish and sharks on prey species, or exclusion of nocturnal foragers/predators aggregating in the immediate vicinity of the vessels at night (Marchesan *et al*., 2006). These aggregations are generally considered to be localised and not associated with long-term changes to fish abundances or distributions. O'Connor *et al*., (2019) studied the ecological impacts of continuous ALAN during the early life history of marine fish and found that whilst juvenile fish grew at a faster rate under these conditions, they were also more susceptible to higher mortality rates.

Light emissions within the OA will be highly localised, short term and not stationary, limiting the ability to result in lasting behavioural responses by fishes in the area. Moreover, the sound emissions from the survey vessel and support vessels would be expected to provide a deterrent to bony fish and elasmobranchs (see **Section 7.2.2**)

It is considered that the consequence of ALAN on bony fish and elasmobranchs within the OA (including for commercially important species as detailed in **Section 4.7.3**) is minor; with any effects expected to be localised, short-term and ceasing when the activity ceases with no detectable adverse effects to the population.

Based on available evidence, it is considered unlikely (uncommon but has been known to occur elsewhere) that artificial lights will impact bony fish and elasmobranchs.

As such, the residual risk of negative impacts to bony fish and elasmobranchs due to artificial lights associated with the Otway Basin 3D MC MSS has been assessed as **Negligible** (*Negligible x Unlikely*) (**Table 49**).

7.5.2.2 Marine Mammals

Many marine mammals have evolved specialised sight or acoustic techniques to enable successful hunting/prey capture in low light, while others are reliant on suitable levels of light and clear water to enable capture. Cetaceans for example use echolocation as their primary sense for locating and hunting prey, followed by visual means at close range (Simmonds *et al.*, 2004). Artificial lights that are fixed or stationary in the marine environment often attract aggregations of zooplankton and then baitfish and/or squid which are prey for species of pinnipeds and dolphins that take advantage of these aggregations for feeding (Golder, 2007). Increased amounts of light at night in the marine environment can also possibly be detrimental to marine mammals by allowing predators to see the mammals more easily during normally dark night times. However, a number of studies have been undertaken on the effects of artificial lighting from oil and gas exploration activities in the GAB on sea lions and cetaceans and concluded that any impacts would be insignificant (Pidcock *et al*., 2003), and similar studies in North West Australia and Canada have found no evidence that cetacean feeding and breeding was being impacted from offshore installations (BHP Billiton, 2005).

The residual risk of artificial light emissions on marine mammals from vessels associated with the Otway Basin 3D MC MSS has been assessed as **Negligible** (*Negligible* x U*nlikely*).

7.5.2.3 Marine Reptiles

As discussed in **Section 4.5.5**, the loggerhead turtle, leatherback turtle and green turtle are known to occur within the OA, each of which are listed species under the EPBC Act as either endangered or vulnerable. There are no species of marine snake known to occur within the OA. The marine turtles are known to use the waters within the OA for foraging and feeding but there are no breeding behaviours known to occur within the OA, or within the wider EMBA.

The Environmental Protection Authority (**EPA**) *Environmental Assessment Guide No. 5 – Protecting Marine Turtles from Light Impacts* (EPA, 2010); the *Recovery Plan for Marine Turtles in Australia 2017-2027* (Commonwealth of Australia, 2017a), and the DoEE Species Profile and Threats Database have been considered as part of the preparation of this EP, and do not identify artificial light from vessels underway in the offshore marine environment as creating a risk for turtles.

The National Light Pollution Guidelines for Wildlife (Commonwealth of Australia 2020) recommends a 20 km nominal distance from light sources to important habitat be applied to protect the conservation value of natural darkness and mitigate potential impacts to marine turtles, however, there are no BIAs for marine reptile species of relevance to the OA.

ALAN from the survey vessels is not expected to have an effect on the foraging and feeding behaviour of turtles within the OA given that the vessels will not be stationary for extended periods of time, and the OA does not represent a particularly important area to foraging marine reptiles as evidence by the lack of BIAs identified in the region.

The residual risk of artificial light emissions on marine reptiles from the vessels associated with the Otway Basin 3D MC MSS has been assessed as **Low** (*Minor* x *Unlikely*).

7.5.2.4 Seabirds

There are twelve seabird species with BIAs reported to overlap the OA and twenty-nine known to occur (**Section 4.5.7**), the majority of which are albatross, petrel and shearwater species. Seabirds are known to commonly strike vessels lit with artificial light at night, particularly vessels with significant exposed rigging/lines. Artificially lit installations, vessels or structures also act to attract seabirds, particularly in otherwise dark areas and for migratory birds travelling at night (Poot *et al.*, 2008). From TGS's previous offshore MSSs in New Zealand and Australia, there have been no bird strikes during night-time.

As stated in the previous section on marine mammals, marine organisms such as zooplankton and small fish are often attracted to artificial light sources and these aggregations can create an enhanced food source for seabirds (Rich and Longcore, 2006). However, as the vessels will be continuously moving during the survey the attraction of zooplankton and baitfish will be highly unlikely to occur, particularly in comparison to fixed lighting sources (e.g. lighthouse, platforms, bridges, etc.).

Seabirds are vulnerable to artificial lighting during nocturnal activities, particularly during the breeding season, through increased predation when leaving and returning to the nesting colony. Cianchetti-Benedetti *et al*. (2018) found artificial light disrupted adult nest attendance, affecting weight gain in chicks. Fledglings are considered more vulnerable to the impacts of artificial light than adults due to unfamiliarity, the immature development of ganglions in the eye at fledging and the potential connection between light and food (Montevecchi, 2006; Mitkus *et al*., 2018). Albatrosses, petrels, and shearwaters are known to aggregate around anthropogenic light sources, with fledging and migratory times particularly vulnerable times for these birds (Le Corre *et al*, 2002; Miles *et al*, 2010; Gjerdrum *et al*., 2021). Strike risk is a potential issue where lit structures intersect flight paths when foraging and during migration (Collins *et al*., 2022).

The National Light Pollution Guidelines for Wildlife (Commonwealth of Australia, 2020) recommends a 20 km nominal distance from light source to important habitat be applied to protect the conservation value of natural darkness and mitigate potential impacts to listed seabirds. Fledglings are more affected by artificial lighting than adults due to the synchronised mass exodus of fledglings from their nesting sites. They can be affected by lights up to 15 km away (Commonwealth of Australia, 2020). There are no breeding BIAs within the OA. The closest known breeding/nesting area for seabirds is reported to be King Island, situated approximately 40 km from the OA at the nearest point. At this distance, there is limited propensity for artificial light to impact seabird breeding/nesting behaviours.

The Draft Wildlife Conservation Plan for Seabirds (Commonwealth of Australia, 2019) characterised light pollution as a moderate risk to seabirds, having a minor impact on individuals but no effect at a population level. The guidance recommends mitigating against impacts of light pollution by boats at sea and around breeding colonies, though no specific management actions are prescribed.

The residual risk of artificial light emissions on seabirds from vessels associated with the Otway Basin 3D MC MSS has been assessed as **Low** (*Minor* x *Unlikely*).

7.5.3 Decision Context

The decision context for Artificial Light Emissions has been assessed as Type A for all receptors, given the predicted impacts and risks are well understood and uncertainty is minimal, with little or no interest from relevant persons.

7.5.4 Identification of Control Measures, Residual Risk Assessment and Demonstration of ALARP

A Hierarchy of Controls methodology (**Table 99**) has been used to assess control measures to determine the benefits in their use towards risk reduction. The control measures that will be implemented during the Otway Basin 3D MC MSS to manage the impacts from artificial light emissions to **ALARP** are included in **Table 100.** The control measures that will be adopted are those that have been assessed and characterised as effective and practicable to implement.

Table 99 Hierarchy of Control Measures for Artificial Light Emissions

Eliminate	Collision prevention and maritime regulations require specific navigation lighting to be implemented. Likewise, provision of safe working conditions at night achieved through employing suitable deck lighting is required to minimise any health and safety incidents. As a result, artificial light emissions cannot be completely eliminated.
Substitute	Navigation lighting cannot be substituted given the requirements cited within the COLGREGs, Marine Order 21 and Marine order 30. Sufficient work lighting cannot be substituted either.
Reduce	Work lighting will be extinguished wherever possible when not required, and as far as practicable work lighting will be focused inwards.
Mitigate	Control measures have been assessed within **Table 100** in order to mitigate the impacts from artificial light emissions to **ALARP** levels. Those which are appropriate and are not impracticable or unfeasible due to disproportionately large costs will be implemented during the Otway Basin 3D MC MSS. Likewise, those which do not diminish the safety of on-board operations and navigation will be implemented during the Otway Basin 3D MC MSS.

Table 100 Assessment of Control Measures for Artificial Light Emissions

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Legislative Requirements:			
The Otway Basin 3D MC MSS will be undertaken in accordance with the approved EP.	P = Yes E = Effective	All vessels undertaking an offshore activity in waters between 3 and 200 NM must undertake that activity in line with an approved EP. The approved EP outlines the measures that will be taken to ensure that environmental effects from the activity will be reduced to **ALARP** and **Acceptable Levels**, including the management of routine permissible waste discharges.	Yes
Adherence to the requirements of the national and international legislation, including the International Regulations for Preventing Collisions at Sea 1972 (COLREGS) and Chapter 5 of Safety of Life at Sea (SOLAS) as implemented in Commonwealth Waters through the *Navigation Act 2012* and associated Marine Orders 21 and 30, including: • Appropriate use of lighting, navigation and radio communication at sea; • 24-hour bridge and radar watch by qualified watch-keepers.	P = Yes E = Effective	It is a legislative requirement to meet the relevant aspects of COLREGs, Marine Order 21 and Marine Order 30 as listed below: • COLREGs Part A (General) • COLREGs Part B (Sound and Light Signals) • COLREGs Part C (Lights and Shapes) • COLREGS Annex I (Positioning and technical details of lights and shapes) • Marine Order 21 (Safety of Navigation and Emergency Procedures) • Marine Order 30 (Prevention of Collisions).	Yes
Good Industry Practice:			
Artificial lighting is reduced to minimum levels, wherever practicable, whilst maintaining safe working conditions and navigation. Specifically, outwards facing lighting will be reduced to minimum levels, wherever practicable.	P = Yes E = Effective	Outward facing lighting is required for navigation/safety/visibility at sea. Work lighting (e.g., in deck areas) will be directed inward as much as possible whilst still supplying the minimum adequate lighting required to maintain safe working conditions for all areas where crew are operating on deck. Navigation lighting to be compliant with relevant guidance for safe passage at sea and specific to each vessel and the activities it is conducting. Good industry practice, environmental benefit outweighs additional cost.	Yes
Development and implementation of Marine Fauna Mitigation Plan.	P = Yes E = Effective	One of the roles of the MFO onboard the Seismic Vessel is to develop a Marine Fauna Mitigation Plan, to be submitted to TGS prior to the pre-mobilisation survey and audit commencing. This plan will demonstrate the following, at a minimum: • MFOs are trained, dedicated and experienced • Responsibilities and authorities of MFOs to ensure the plan is communicated and available to those roles that are required to implement the controls; • Communications protocols for relaying marine fauna observations to the Seismic Operator, Vessel Master and vessel crew as required. • Survey Plan – describes the proposed activity including location and timing, acoustic source and streamer configuration, equipment (vessels) and key geographic locations such as BIAs and nominated exclusion zones. • Implementation Plan – details how the marine fauna management controls within the EP will be implemented; • Handling procedures for the retrieval of marine fauna entangled in towed equipment or seabirds on the vessels' deck. Good industry practice, environmental benefit outweighs additional cost.	Yes
Seabird collisions (both fatal and non-fatal) with the survey vessels will be recorded.	P = Yes E = Partial	The National Light Pollution Guidelines recommends that bird strikes are recorded. All crew will be instructed to remain vigilant for seabird collisions with the survey vessels (such as grounding on the vessels deck) and any observed/discovered incidents will be recorded and reported within the final survey report. Good industry practice, environmental benefit outweighs additional cost.	Yes

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Alternatives/Substitutes Controls Considered:			
Use of lighting sources with wavelengths that are less disruptive to marine organisms, as listed in the National Light Pollution Guidelines for Wildlife.	P = No E = No	Given the large variety of marine organisms that may be present, and that their varying sensitives to different light wavelengths, this control measure is not regarded as being practical and is likely to be of minimal overall benefit. The costs of replacing lighting are also considered disproportionate to any benefit gained.	No
Eliminate lighting.	P = No E = Very Effective	Adequate lighting is required for safe work of all crew onboard the vessels and navigation lighting is required for collision avoidance and visibility at sea. Safety costs are disproportionate to benefits.	No
Additional Controls:			
Inward/downward facing lighting only.	P = No E = Effective	Outward facing lighting is required for navigation/safety/visibility at sea, in accordance with the COLREGS, Marine Order 21 and Marine Order 30. It is a regulatory requirement to have appropriate navigation lighting on all vessels from sunset to sun rise. However, there are benefits to ensuring deck/workspace lighting is inward/downward facing to reduce light spill as far as reasonably practicable, see directional lighting control measure above.	No
Use of non-reflective, dark-colour surfaces.	P = No E = Effective	As the survey vessels have already been built, changes to the ship materials to follow all design principles of Best Practice Lighting Design would require a re-fit of the vessels. The costs of doing this are considered disproportionate to any benefit gained	Yes
No acquisition during hours of darkness.	P = No E = Effective	This measure would effectively double the time to acquire the Otway Basin 3D MC MSS. By extension, this would extend the duration of disturbance to sensitive environmental receptors and would increase potential conflict and displacement with commercial and recreational fishers. Additionally, vessels would remain at sea necessitating they display navigation lighting and provide safe amounts of deck lighting for crew even if not acquiring data (e.g., during darkness hours). Consequently, costs are considered disproportionate to benefits.	No
Use of filters over existing lighting.	P = No E = Partial	Filters can be fitted over lights to eliminate shorter light wavelengths. This control measure is not regarded as being practical and is likely to be of minimal overall benefit. Significant light impacts to birds and turtles are not expected due to the transient nature of the survey and support vessels and the offshore location of the survey. Given the time and cost required to change lighting, this option was considered impractical and disproportionate to the limited benefit that would be gained.	No

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Data acquisition will only occur outside of seabird breeding/nesting periods.	P = No E = Limited Effectiveness	The OA is located 40 km from the nearest known seabird nesting area. The National Light Pollution Guidelines for Wildlife recommends a nominal distance of 20 km from important habitat in order to minimise any potential adverse effects. As discussed within Section 7.5.1, the light source will constantly be moving; any attraction, distraction or disorientation of seabirds would be highly unlikely, particularly in comparison to a fixed light source. Therefore, any minor environmental gains from limiting data acquisition periods to outside of key nesting periods are considered to be at a disproportionally increased cost to the survey. Therefore, this control measure is considered to provide limited overall benefit.	No
Residual Risk of Impact (Receptor)	**Consequence**	**Likelihood**	**Residual Risk Ranking**
Fish, Sharks, Rays	Negligible	Unlikely	Negligible
Marine Mammals	Negligible	Unlikely	Negligible
Marine Reptiles	Minor	Unlikely	Low
Seabirds	Minor	Unlikely	Low
ALARP Statement			
The decision context has been assessed as Type A and the overall residual risk has been determined to range from Negligible to Low for the identified receptors. TGS considers the adopted control measures are appropriate to manage the impacts of artificial light emissions during the Otway Basin 3D MC MSS. The proposed control measures have been developed in accordance with the legislative requirements and good industry practice and take into account the specific environmental, social, economic and cultural characteristics of the OA. No effective and practicable alternative or additional control measures were identified as part of the assessment process. Therefore, the predicted impacts to receptors from artificial light emissions are reduced to **ALARP.**			

7.5.5 Impact and Risk and Acceptability

Table 101 Demonstration of General Impact and Risk Acceptability for Artificial Light Emissions

Criteria for Acceptance	Acceptability Summary
Residual Risk Ranking	The Residual Risk has been determined to range from Negligible to Low.
Ecologically Sustainable Development	The management of the impact and risks associated with artificial light emissions proposed by TGS can be carried out in compliance with the five principles of ecologically sustainable development as defined within the EPBC Act. These principles have been considered as part of the development of this EP and risk assessment process. The assessment has not identified any adverse impacts to the principles of ESD, with no threats of serious or irreversible damage, no impacts to biological diversity and ecological integrity, no degradation of inter-generational equity, or negative effects on the social and economic integrity in the short or long-term.
TGS's Internal Context	The proposed management of the risks associated with the establishment of IMS is consistent with TGSs QHSE Policy commitments of: • Protecting the environment; and • Conducting operations in an environmentally sustainable and responsible manner.
Existing Environmental Context	Given that the survey vessels, and ultimately artificial light source, involved in the Otway Basin 3D MC MSS will be constantly moving and the relatively low amounts of artificial light that will be emitted from the vessels, the impacts to the marine environment from artificial light emissions are likely to be short term, highly localised, and quickly recoverable. While the OA is overlaps BIAs of several shark, mammal and seabird species, the levels of artificial light emission will be similar or less (with mitigation measures in place) to those generated from maritime traffic in the area associated with coastal shipping and fishing activity. The proposed control measures provide appropriate protection to the marine environment from artificial light emissions. Further/alternative control measures (such as no night-time acquisition) are considered to provide little or no further protection from artificial light emissions, while greatly increasing the duration and cost of the survey. Increases to the duration of the survey are particularly prohibitive as it increases the time environmental receptors are exposed to disturbance and also increases the potential for conflict and displacement with the fishing industry. As a result, no further/alternative control measures have been adopted.
External Context – Management Plans, Species Recovery Plans and Conservation Advice	The residual risk of the artificial light emissions has been determined to range between Negligible to Low and will not have a significant impact on a matter of national environmental significance in accordance with EPBC Act Policy Statement 1.1. The following Management Plans, Species Recovery Plans and Conservation Advices have been taken into consideration when determining the acceptability of effects of artificial light emissions: **Recovery Plan for Marine Turtles in Australia (Commonwealth of Australia 2017)** The recovery plan for marine turtles recommends that best practice light management is undertaken to minimise light impacts to marine turtles, so their behaviours are not changed, and they do not become displaced from important habitats. There are no turtle breeding grounds within the OA or EMBA. The proximity of the OA to marine turtle foraging BIAs is not of concern, given that marine turtle foraging is generally constrained to daylight hours when artificial light generated by the survey vessel will be minimal. The proposed activities are considered consistent with the objective of facilitating recovery of marine turtles. **Draft Wildlife Conservation Plan for Seabirds 2019** The Draft Wildlife Conservation Plan for Seabirds objectives seek to manage and minimise the adverse impacts of anthropogenic disturbance to breeding and roosting seabirds and enhance contingency plans to prevent, respond to or remediate environmental emergencies that have an impact on seabirds and their habitats. Given there is no emergent land within the OA and the closest known seabird breeding/nesting site is King Island, approximately 40 km east of the OA, the lighting control measures proposed herein, and transient nature of the light source generated from the moving Seismic Vessel means that the planned survey approach is compliant with the objectives of the conservation plan. The proximity of the OA to seabird foraging BIAs is not of concern, given that foraging for seabirds is mostly constrained to daylight hours when artificial light generated by the Seismic Vessel will be minimal. A 20 km distance threshold between light source and important seabird habitat is recommended to be maintained, according to the National Light Pollution Guidelines for Wildlife (Commonwealth of Australia 2020). Given that the closest seabird breeding/nesting site is King Island, located approximately 40 km east of the OA, the Otway Basin 3D MC MSS is compliant with the relevant Commonwealth guidelines. The proposed activities are considered consistent with the objective of facilitating conservation of seabird populations. **Conservation Management Plan for the Blue Whale;** **Approved Conservation Advice for *Megaptera novaeangliae* (humpback whale); and** **Conservation Advice for Sei and fin Whales** The conservation and management guidance does not identify artificial light pollution as a threat to relevant species and no management actions are prescribed. Artificial light emissions generated during the Otway Basin 3D MC MSS are not predicted to impact blue whale, humpback whale, Sei or fin whales. The proposed activities are considered consistent with the conservation and recovery of relevant species. **AMP Values, Management Prescriptions and IUCN Reserve Management Principles** The management prescriptions for AMPs do not include information on artificial light emissions from commercial vessels.

Criteria for Acceptance	Acceptability Summary
	<u>**Conservation values and objectives of the South-east Commonwealth Marine Reserves Network Management Plan 2013 – 2023**</u> Artificial light emissions are not expected to impact significantly on the environmental values or sensitivities of the SEMR at a local or regional level.
Social Acceptance – Relevant Person Expectations	Concerns were raised by relevant persons around the potential impacts of artificial light emissions on seabirds given the Otway Basin 3D MC MSS will be operating 24/7. Although no additional control/mitigation measures have been put in place with regard to light emissions, the control measures associated with industry best practice are considered appropriate to ensure the environmental impacts relating to light emissions from survey vessels are considered to be at socially **Acceptable Level.**
External Context – Commonwealth and State Legislative Criteria	Lighting requirements for the Otway Basin 3D MC MSS are determined by relevant legislative requirements (i.e., COLREGS, SOLAS, Marine Order 21 and Marine Order 30). Legislated requirements for safe working conditions and safe navigation will be met.
Industry Best Practice	The control measures to decrease artificial light emissions are based on industry best practice and best practice guidelines, including: • The IAGC Environmental Manual for Worldwide Geophysical Operations. Geophysical vessels must ensure that their emissions are kept to appropriate levels; and • The APPEA Code of Environmental Practice. Details within this document relate mainly to offshore operations such and offshore exploration/drilling and production facilities where light emissions are recommended to be reduced to **ALARP** and **Acceptable Levels**. A similar approach could feasibly be expected of survey vessels operating in offshore areas.
ALARP	Total elimination of all impacts associated with artificial lighting emissions cannot be achieved, as lighting must be used onboard the vessels to maintain safe operations and navigation and there are no practicable alternatives. Following the implementation of the control measures, the potential impacts to the marine environment and associated receptors from artificial light emissions are likely to be short term and localised. Based on the assessment within this EP, including the potential impacts on the environment and the associated controls measures to be implemented, the impact of artificial light emitted from the survey vessels is considered to be **Low** and reduced to **ALARP**. Therefore, the impacts and associated residual risk from this activity are considered to be at an **Acceptable Level**.

Acceptability Statement
Impacts and risks classified as 'Type A' or above are considered acceptable if the requirements in **Table 51** can be demonstrated and if the level of residual impact and risk are determined to be Moderate or less**.** Based on the above evaluation, the potential impacts from artificial light emissions meets the requirements of the impact and risk acceptability criteria. The control measures that will be implemented throughout the Otway Basin 3D MC MSS have been developed in accordance with these criteria and are considered appropriate to manage the impacts of artificial light emissions on all identified receptors to an **Acceptable Level.**

7.5.6 Environmental Performance

Table 102 Environmental Performance Outcomes, Standards and Measurement Criteria for Artificial Light Emissions

Number	Environmental Performance Outcome	Environmental Performance Standard
EPO 23	Lighting is reduced to levels required to support safe navigation and on-board operations, so as to limit impacts from artificial light to individual non-listed, listed threatened, listed migratory or listed marine fauna protected under the EPBC Act to minor, short term effects and ensure biologically important behaviours can continue.	**EPS 199** to **EPS 206**

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
The Otway Basin 3D MC MSS will be undertaken in accordance with the approved EP.	**EPS 199**: The Otway Basin 3D MC MSS may only commence following acceptance of the EP by NOPSEMA.	Pre-mobilisation audit and inspection are completed prior to operations and confirm an accepted EP has been obtained. Audit records verify compliance with the requirements of the EP.	TGS VOM EA
	EPS 200: The Otway Basin 3D MC MSS will be undertaken in accordance with the accepted EP.	Bridge logs verify compliance with the requirements of the EP. Audit records verify compliance with the requirements of the EP.	TGS VOM VOC EA Vessel Master SEA
Adherence to the requirements of the national and international legislation, including the International Regulations for Preventing Collisions at Sea 1972 (COLREGS) and Chapter 5 of Safety of Life at Sea (SOLAS) as implemented in Commonwealth Waters through the *Navigation Act 2012* and associated Marine Orders 21 and 30, including: • Appropriate use of lighting, navigation and radio communication at sea; • 24-hour bridge and radar watch by qualified watch-keepers.	**EPS 201**: Vessel navigational lighting and equipment is compliant with COLREGs, SOLAS and Marine Orders 21 and 30.	Vessel certification confirms compliance with applicable Regulations.	VOC Vessel Master Party Chief
Artificial lighting is reduced to minimum levels, wherever practicable, whilst maintaining safe working conditions and navigation. Specifically, outwards facing lighting will reduced to minimum levels, wherever practicable.	**EPS 202**: Vessel crews are instructed to reduce artificial lighting levels, wherever practicable, whilst maintaining safe working conditions and navigation during an Environmental Induction.	Induction records show Environmental Induction includes instruction on the measures to reduce artificial lighting levels, whilst maintaining safe working conditions and navigation in accordance with the COLREGS, Marine Order 21 and Marine Order 30. Induction records confirm vessel crew attended an Environmental Induction.	Party Chief SEA CSR
	EPS 203: Non-essential lighting will be switched off when not in use.	Pre-mobilisation audit and inspection prior to operations beginning identifies any non-essential lighting, along with vessel crew inductions.	Vessel Crew
	EPS 204: External lighting will be directed inboard and onto the deck where practicable.	Pre-mobilisation audit and inspection prior to operations beginning identifies the opportunity to direct external lighting inward, along with vessel crew inductions.	Party Chief

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
	EPS 205: Essential navigation lighting to maintain compliance with COLREGS, Marine Order 21 and Marine Order 30 is required.	Vessel certification confirms compliance with applicable Regulations Induction records show Environmental Induction includes instruction on the measures to reduce artificial lighting levels, whilst maintaining safe working conditions and navigation in accordance with the COLREGS, Marine Order 21 and Marine Order 30.	Party Chief
Development and implementation of Marine Fauna Management Plan.	**EPS 206:** One of the roles of the MFO onboard the Seismic Vessel is to develop a Marine Fauna Mitigation Plan, to be submitted to TGS prior to the pre-mobilisation survey and audit commencing. This plan will demonstrate the following, at a minimum: • MFOs are trained, dedicated and experienced • Responsibilities and authorities of MFOs to ensure the plan is communicated and available to those roles that are required to implement the controls; • Communications Plan – details the protocols for relaying marine fauna observations to the Seismic Operator, Vessel Master and vessel crew as required. • Survey Plan – describes the proposed activity including location and timing, acoustic source and streamer configuration, equipment (vessels) and key geographic locations such as BIAs and nominated exclusion zones. • Implementation Plan – details how the marine fauna management controls within the EP will be implemented; and • Handling procedures for the retrieval of marine fauna entangled in towed equipment or seabirds on the vessels' deck.	Pre-mobilisation audit and inspection confirms the Marine Fauna Management Plan has been developed Induction records outline the content of inductions and personnel present. MFOs daily and weekly logs and Bridge logs confirm the Marine Fauna Mitigation Plan is being implemented.	MFO EA SEA CSR

7.5.7 Artificial Light Emission Impact and Risk Summary

Based on the assessment above, including the identification of potential impacts on the environment and the associated controls measures to be implemented, the impact of artificial lights emissions generated from the survey vessels is considered to be **Low.**

The suite of control measures to be implemented have been developed in accordance with Industry Best Practice and relevant legislation. Consequently, it is considered that the environmental impacts and risks on the marine environment and receptors arising from artificial light emissions are reduced to **ALARP**.

In accordance with the acceptability requirements prescribed in **Section 6.4**, the suite of control measures is considered appropriate to manage the risks and impacts arising from artificial light emissions during the Otway Basin 3D MC MSS on all receptors to an **Acceptable Level**.

8 Environmental Impacts and Risks from Unplanned Activities

Unplanned activities are those that are non-routine and are rare during MSS operations. However, the potential impacts and risks associated with any unplanned events must be given serious consideration as their consequences can be severe. The impact and risk assessment has been undertaken for each unplanned activity listed in **Table 103**.

Table 103 Unplanned Activities Assessed

Unplanned activity	Section reference	Residual risk
Introduction of invasive marine species	**Section 8.1**	Low
Streamer loss	**Section 8.2**	Low
Vessel collision, sinking or bunkering incident and associated hydrocarbon spill	**Section 8.3**	Low
Hydrocarbon spill response	**Section 8.4**	Low
Accidental release of hazardous and non-hazardous materials	**Section 8.5**	Low

This section of the EP goes through the impact and risk evaluation for each of the unplanned activities listed above that could potentially be associated with the Otway Basin 3D MC MSS, for each of the receptors of relevance within the OA and wider environment should such an incident occur, using the methodology described within **Section 6**. This evaluation will demonstrate that the impacts and risks associated with the Otway Basin 3D MC MSS will be reduced to **ALARP** and will be of an **Acceptable Level**. This will be achieved largely through the implementation of control measures, operational procedures and operating to Good Industry Practice.

8.1 Introduction of Invasive Marine Species

8.1.1 Description of Source of the Impact and Risk

Invasive marine species (**IMS**) are foreign marine aquatic plants and animals that have colonised and established new populations in areas beyond their natural range. IMS are typically carried as larvae or juveniles on international vessels, either in niche areas on vessel hulls or in their ballast and/or bilge water. The survey vessels associated with the Otway Basin 3D MC MSS have the potential to introduce IMS through the discharge of ballast water containing IMS (either as adults and juveniles or eggs/larvae) or through translocation of IMS through biofouling of the vessel hull, internal seawater systems, or immersible equipment (i.e. towed equipment).

As most species have well defined tolerances to environmental conditions (e.g. temperature, salinity, light), not all introduced species successfully colonise new environments. However, if the source and destination environments are sufficiently similar, larvae may successfully establish new colonies which may outcompete and/or predate on native species, causing environmental impacts that are often difficult to control. Likewise, incursions of highly adaptable species, able to successfully proliferate under dynamic environmental constraints, pose similar risks to native species ecology and persistence. Shallow coastal marine environments surrounding key maritime infrastructure are particularly susceptible to the colonisation of IMS, which largely reflects the accidental transport of IMS by international shipping to marinas and ports (Wells *et al*., 2009).

An introduced species is only considered 'invasive' once it begins to cause negative consequences on its new environment (Bax *et al.*, 2003) and once established, marine pests are usually difficult to manage or eradicate (Fletcher *et al.*, 2017). For an IMS to become established, there are various conditions which must be met, including surviving the introduction process, ability to overcome abiotic factors and adapt to a new trophic niche, and the ability of the recipient environment to facilitate survival and establishment (Streftaris *et al.*, 2005). Gebuzri and McCarthy (2018) suggest that there are several ecological and life-history traits which regularly occur in IMS from different taxa and can be associated with their success. Many of these traits are associated with reproduction, including having the ability to form resting stages, a life-history strategy consisting of pelagic larval dispersal or direct development, having a high reproductive rate and plasticity in resource utilisation (Gebuzri and McCarthy 2018).

The '*National Biofouling Management Guidance for the Petroleum Production and Exploration Industry*' states that immersible equipment associated with MSSs do not normally pose a threat for biofouling accumulation and translocation as most components are generally free of biofouling, except for the streamers which may accumulate biofouling organisms in the joints. The most likely biofouling organisms in open, deep waters growing on the streamers are goose barnacles and green filamentous seaweed which are not considered marine pests (Marine Pest Sectoral Committee, 2018).

The NOPSEMA information paper '*Reducing marine pest biosecurity risks through good practice biofouling management*' (NOPSEMA paper N-04750-IP1899) states that, at a minimum, NOPSEMA expects titleholders, and their contracted vessels apply relevant guidance from the IMO Biofouling Guidelines. These guidelines provide an internationally consistent approach to biofouling management and record keeping, with the key recommendation being the development and implementation of a Biofouling Management Plan and Biofouling Record Book. These guidelines have been adopted as control measures within **Table 109.**

IMS and diseases translocated by shipping, fishing vessels, other vessels and tourism have been identified as a source of pressure on the conservation values of the South-east Marine Reserves Network within the South-east Commonwealth Marine Reserves Network Management Plan 2013 – 2023.

8.1.2 Evaluation of Known and Potential Impacts and Risks to Environmental Receptors

Using the information presented in **Section 4** to **Section 5**, the impact and risk assessment has been undertaken for those receptors determined to be relevant to the activity, as listed in **Table 104**.

Table 104 Environmental Receptors Assessed

Receptor	Section reference
Plankton	**Section 8.1.2**
Benthic habitats (banks, shoals and reefs)	
Benthic invertebrates	
Marine fauna	
EPBC Act listed marine fauna	
Marine protected areas and sensitive areas	

Once introduced, IMS can have significant and irreversible impacts on the marine ecosystem. Due to a lack of natural competitors or predators, the following adverse effects on the receiving environment may occur following the establishment of an IMS:

- Out-competing and/or displacing native species;
- Increase in predation and possible depletion of native flora and fauna; and
- Changing the nature of the environment through altering the abundance and diversity of native species, resulting in a change to the functioning of the communities.

The establishment of IMS can have consequences which cascade through the trophic structure, affect commercially important species and aquaculture, or which impact other marine users.

Should an IMS population establish, the management options available to regulatory agencies are limited primarily to continual monitoring and control of the IMS population, or to mitigating the impacts from its establishment. Such measures are commonly associated with a high economic or labour encumbrance.

The OA is unlikely to support the establishment of IMS due to the unfavourable water depths (approximately 97 – 5,000 m) and the limited availability of suitable habitat. Areas of hard substrate and topographic relief supporting benthic species may occur in association with the Zeehan AMP (**Section 4.4**) and the West Tasmania Canyons (**Section 4.4.3**). Successful establishment of IMS in relation to these substrates could potentially result in long-term impacts to the regionally significant ecological communities present.

Highly disturbed, shallow water environments (e.g. ports and marinas) are more susceptible to colonisation than open-water environments such as the OA, where the rate of dilution and the degree of dispersal are high Williamson and Fitter, 1996; Paulay *et al*., 2002). However, the risk of an IMS establishing itself as result of the Otway Basin 3D MC MSS is no different than the various shipping operations (e.g. commercial shipping and commercial fishing) that occur within the wider Otway Basin and GAB. The biosecurity of these vessel movements is regulated by various legislative requirements which are considered to be industry best practice. These requirements have been utilised to form the basis of the control measures outlined in **Section 8.1.3**.

Prior to entering Australian waters, all vessels are required to obtain DAFF biosecurity clearance (via submission of a Pre-Arrival Report at least 12 hours prior to arrival) to confirm that the vessel is meeting requirements of the *Biosecurity Act 2015* for entry into Australian waters. Survey mobilisation will only occur after clearance is received and a valid anti-fouling certificate is confirmed. Valid hull anti-fouling certificates will meet the requirements of Annex 1 of the International Convention on the Control of Harmful Anti-Fouling Systems on Ships and the requirements of the *Protection of the Sea (Harmful Antifouling Systems) Act 2006*.

Vessels arriving in Australian waters, will also be required to adhere to the Australian Ballast Water Management requirements, including restrictions on exchange of ballast water to the open ocean. Vessels will not exchange ballast water within 12 NM of the Australian coastal baseline or in water depths of less than 50 m (noting the shallowest depth in the OA is approximately 97 m).

Submersible equipment used as part of survey activities may on occasion be retrieved out of the water such as for maintenance purposes and during transit. The time this equipment spends outside of the water will facilitate the desiccation and death of any biofouling present. Streamers are also routinely cleaned to prevent excessive biofouling that could lead to interference of the received signal, and consequently, the quality of the seismic data. Inspection, cleaning and maintenance of survey equipment during retrieval will be implemented as a management measure throughout the Otway Basin 3D MC MSS.

Based on the control measures that will be implemented, it is considered that the residual risk of introducing IMS as part of the Otway Basin 3D MC MSS is **Low** (*severe x remote).*

8.1.3 Evaluation of Known and Potential Impacts and Risk to Other Marine Users

Using the information presented in **Section 4** to **Section 5**, the impact and risk assessment has been undertaken for those receptors determined to be relevant to the activity as listed in **Table 105**.

Table 105 Relevant Persons and Other Marine Users Assessed

Receptor	Section reference
Commercial fisheries	**Section 8.1.3**
Commercial shipping	
Tourism and recreation	
Divers (commercial and recreational)	
Petroleum exploration and production activities	

Potential risks from the establishment of an IMS to relevant persons and other marine users include:

- Impacts on human health through presence and/or release of toxins or toxic tissues;
- Predation (leading to depletion) of, and competition with, commercial stocks, including wild fisheries and aquaculture, and/or impacts to their associated habitats;
- Nuisance biofouling causing damage to and/or smothering of industrial marine equipment or local infrastructure;
- Impacts to shipping logistics, efficiency and feasibility; and
- Reduction of aesthetics in coastal environment and/or water column.

Several identified relevant persons associated with the OA rely on the presence and use of healthy native flora and fauna and ecologically sustainable populations. As outlined above, in the unlikely event of the establishment of an IMS, these native flora and fauna could be displaced either through direct establishment of the IMS, through increased predation and competition or as a result of changes in environmental conditions driven by the IMS ecology.

Commercial abalone fishers around Portland (VIC) are currently being impacted by the abalone viral ganglioneuritis and have raised specific concerns about the further introduction and spread of fish disease from the operation of the survey vessels (see **Section 5** and **Appendix K**). TGS will adopt strict biosecurity control measures (see **Table 107**) to ensure there is no introduction or spread of disease as a result of vessel movement during the Otway Basin 3D MC MSS.

The residual risk of introducing IMS during the Otway Basin 3D MC MSS has been assessed as **Low** (*severe* x *remote*).

8.1.4 Decision Context

The decision context for the introduction of IMS has been assessed as Type A given the predicted impacts and risks are well understood and uncertainty is minimal, with little or no interest from relevant persons.

8.1.5 Identification of Control Measures, Residual Risk Assessment and Demonstration of ALARP

Control measures that will be put in place during the Otway Basin 3D MC MSS to manage the potential risks associated with IMS to **ALARP** have been listed in **Table 107**. TGS has considered a number of control measures to determine the benefits of their implementation towards risk reduction based on a Hierarchy of Controls methodology (**Table 106**). The control measures that will be adopted are those that have been assessed and characterised as effective and practicable to implement.

Table 106 Hierarchy of Control Measures for the Introduction of Invasive Marine Species

Eliminate	To completely eliminate the risk of the establishment of any IMS, the transport of vessels into Australian waters would need to be eliminated. However, the Otway Basin 3D MC MSS cannot be conducted without the use of a Seismic Vessel and such vessels are unlikely to be available in Australian waters.
Substitute	As per the above, and at this point in time, there are no validated approaches which could be adopted to gather information on geologic formations below the seabed at the required resolution. Therefore, there is no substitute to a seismic vessel undertaking the Otway Basin 3D MC MSS.
Reduce	Control measures to reduce the risk of the establishment of IMS have been detailed within **Table 107**. These include restriction to the discharge of ballast water, maintenance of adequate anti-fouling systems and cleanliness of the vessels undertaking the Otway Basin 3D MC MSS.
Mitigate	Control measures have been assessed within **Table 107** to mitigate the risks of an IMS establishing within the OA or connected marine environments. The risks of unplanned activities should be eliminated, substituted or reduced, with mitigation primarily used for those activities in which impacts will occur. However, TGS will report any sighting or suspicion of IMS as per the measure outlined in **Table 107** in order to mitigate the potential impacts to **ALARP**.

Table 107 Assessment of Control Measures for the Introduction of Invasive Marine Species

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Legislative Requirements:			
The Otway Basin 3D MC MSS will be undertaken in accordance with the approved EP.	P = Yes E = Effective	All vessels undertaking an offshore activity in waters between 3 and 200 NM must undertake that activity in line with an approved EP. The approved EP outlines the measures that will be taken to ensure that environmental effects from the activity will be reduced to **ALARP** and **Acceptable Levels**, including the management of IMS.	Yes
Adherence to the Australian Ballast Water Management Requirements (Version 8). Vessels will manage ballast water exchange/discharge using one of the following approved methods of management: • An approved ballast water management system; • Ballast water exchange conducted in an acceptable area (as defined in the Ballast Water Management Requirements (Version8)); • Use of low-risk ballast water (such as fresh potable water, high seas water or fresh water from an on-board fresh water production facility); • Retention of high-risk ballast water on board the vessel; or • Discharge to an approved ballast water reception facility.	P = Yes E = Effective	Compliance with these requirements will reduce the risk of potential IMS from establishing within the Otway Basin from the discharge of ballast water. It is a legislative requirement for vessels to comply with the Biosecurity Act 2015.	Yes
In accordance with the Ballast Water Management Requirements (Version 8), vessels will not exchange ballast water within 12 NM from the nearest land and in water depths of less than 50 m unless sourced from Australian waters.	P = Yes E = Effective	Regulation D-2 of the Ballast Water Management Convention as implemented through the Australian Ballast Water Management Requirements, requires vessel s to exchange ballast water at least 12 NM from the nearest land and in water at least 50 m deep. Compliance with these requirements will reduce the risk of potential IMS establishing through the discharge of ballast water. It is a legislative requirement for vessels to comply with the Biosecurity Act 2015.	Yes
Vessels will have a Ballast Water Management Plan in place and valid Ballast Water Management Certificate (unless an exemption applies or is obtained from (DoCCEEW).	P = Yes E = Effective	As each ship is different, so are ballast water management practices. As such, having a Ballast Water Management Plan and Ballast Water Management Certificate appropriately maintained for each relevant vessel is important so that the potential for the introduction and establishment of IMS is reduced to **ALARP**. The Ballast Water Management Plan details the approved ballast water management method while the Ballast Water Management Certificate verifies the vessel has been surveyed to a standard compliant with the IMO Ballast Water Management Convention. This control measure is in accordance with the Australian Ballast Water Management Requirements and is a legislative requirement for vessels to comply with the Biosecurity Act 2015.	Yes
All vessels will maintain a complete and accurate Ballast Water Record System that is consistent with the Ballast Water Management Requirements (Version 8).	P = Yes E = Effective	The Ballast Water Record System identifies when ballast water is taken on board, circulated, or treated for ballast water management purposes, and discharged to the sea or a reception facility, and accidental or other exceptional discharges of ballast water. Ballast water records will be used to confirm that ballast water management is undertaken in accordance with the Australian Ballast Water Management Requirements. It is a legislative requirement for vessels to comply with the Biosecurity Act 2015.	Yes
Vessels entering Australian territorial waters will obtain all the necessary DAFF biosecurity approvals, prior to mobilisation.	P = Yes E = Effective	Operators of all vessels utilised during the Otway Basin 3D MC MSS will provide information on how biofouling has been managed prior to arriving in Australian territorial seas through DAFF Pre-Arrival Report. Clearance confirms that the vessels meet the requirements of the Biosecurity Act 2015 for entry into Australian waters, including review of a ballast water report by a biosecurity officer. Mobilisation of the vessels to the OA will only occur after clearance is confirmed. Clearance confirms that the vessel does not present a high risk to the marine environment in Australian waters and therefore reduces the likelihood of IMS being introduced. The Ballast Water Report provided during reporting identifies if the vessel has or intends to discharge internationally sourced ballast water, and management will be conducted as determined by DAFF. It is a legislative requirement for vessels to comply with the Biosecurity Act 2015.	Yes

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
All vessels utilised for the Otway Basin 3D MC MSS will hold a valid Ship Sanitation Control Certificate or Ship Sanitation Control Exemption Certificate.	P = Yes E = Effective	Under the Biosecurity Act 2015, the DAFF requires all vessels visiting Australian waters for the purpose of the Otway Basin 3D MC MSS to hold a valid Ship Sanitation Control Certificate or Ship Sanitation Control Exemption Certificate. DAFF administers Ship Sanitation Certification requirements on behalf of the Department of Health. These documents are aimed at controlling the spread of international listed human diseases by controlling any vectors of the diseases that could potentially be carried on a vessel. This is achieved by inspecting for and controlling animal vectors (rodents and mosquitoes), preventing the discharge of untreated ballast water, checking certification of potable water and sewage, and biosecurity measures for human carriers of disease. Australian renewal of a ship sanitation control exemption certificate may be requested by the master or agent of a vessel when submitting the PAR or by submitting a Ship Sanitation Certificate Service Request through the DAFF Maritime and Aircraft Reporting System. It is a legislative requirement for vessels to comply with the Biosecurity Act 2015.	Yes
All vessels utilised for the Otway Basin 3D MC MSS will demonstrate proactive management of biofouling prior to entering Australian territorial waters by implementing one of the following three accepted proactive biofouling management options: • Implementation of an effective biofouling management plan; • Cleaned all biofouling within 30 days prior to arriving in Australian territory; or • Implementation of an alternative biofouling management method pre-approved by DoCCEEW.	P = Yes E = Effective	This control measure aligns with the Australian Biofouling Management Requirements (Version 1) which provide guidance for vessel operators on best practice measures to avoid the introduction of IMS into Australia. It is a legislative requirement for vessels to comply with the Biosecurity Act 2015.	Yes
Effective anti-fouling systems and management practices are adopted for each vessel that complies with the requirements of Annex 1 of the International Convention on the Control of Harmful Anti-Fouling Systems on Ships and the requirements of the Protection of the Sea (Harmful Antifouling Systems) Act 2006. Anti-foul systems used on the vessel will not consist of harmful anti-fouling compounds (i.e. an organotin compound that acts as a biocide in an anti-fouling system, or cybutryne) or each harmful anti-fouling compound that is applied on external surfaces has a coating that forms a barrier to the compound leaching into the water, or, for a ship that has cybutryne applied on a designated external surface, neither of the following has occurred; i) the first scheduled renewal of the ships' anti-fouling system after 1 January 2023, ii) the day that is 60 months after the last application of cybutryne to the ship before 1 January 2023.	P = Yes E = Effective	Annex 1 of the International Convention on the Control of Harmful Anti-Fouling Systems on Ships and the Protection of the Sea (Harmful Antifouling Systems) Act 2006 prohibit ships from bearing or applying organotin compounds which act as biocides in anti-fouling systems and require vessels to carry a current international anti-fouling system certificate. Anti-foul systems used on the vessel will not consist of harmful anti-fouling compounds (i.e. an organotin compound that acts as a biocide in an anti-fouling system, or cybutryne) or each harmful anti-fouling compound that is applied on external surfaces has a coating that forms a barrier to the compound leaching into the water, or, for a ship that has cybutryne applied on a designated external surface, neither of the following has occurred; i) the first scheduled renewal of the ships' anti-fouling system after 1 January 2023, ii) the day that is 60 months after the last application of cybutryne to the ship before 1 January 2023. Anti-fouling paint systems are one of the primary methods for preventing the establishment and translocation of fouling species. Therefore, having an effective anti-fouling system in place onboard the survey vessels will reduce the potential for IMS to attach to the vessels, and subsequently establish in new areas. Each vessel is to have documented anti-fouling management procedures, involving periodic in-water and/or dry-dock inspections. A current international anti-fouling system certificate will be carried by each vessel associated with the Seismic Survey. It is a legislative requirement for vessels to comply with the Protection of the Sea (Harmful Antifouling Systems) Act 2006.	Yes
Good Industry Practice			
All vessels will have 'clean' hull and niche areas upon arrival with a written report from a qualified marine biologist on the biofouling inspection. A Marine Biofouling Inspector will be contracted in accordance with the requirements set out in **Section 10.3.1** to ensure this.	P = Yes E = Effective	Checking or evidence of recent inspection that the vessel hulls and niche areas are clean prior to arrival within the OA will reduce the likelihood of any IMS travelling with the vessel en-route to the area. Due to this fact, the ability for an IMS to establish itself due to the proposed activities will be reduced to **ALARP**. A Marine Biofouling Inspector will be contracted in accordance with the requirements set out in **Section 10.3.1** to evaluate the risk profile of the survey vessel/s. When assessing the risk profile of the survey vessel/s, the Marine Biofouling Inspector will take into consideration the following (note that this is not an exhaustive list): • The age, type and condition of the vessel and anti-fouling coating;	Yes

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
		• Previous biofouling cleaning and inspections that have been undertaken on the vessel/s and the outcomes of these previous inspections; • An assessment of internal niches with potential to harbour IMS and presence and condition of internal seawater treatment systems; • The vessel's history since the last inspection, including the origin of the vessel and its potential for exposure to IMS and subsequent translocation risk; • An assessment of the vessel's Biofouling Management Plan and record book against the IMO Biofouling Guidelines; and • In water specifications where appropriate. Environmental benefit outweighs additional cost.	
Survey equipment to be inspected, cleaned, and dried prior to deployment in the OA or Australian territorial waters.	P = Yes E = Effective	As per the above, checking that equipment proposed to be used for the Seismic Survey is clean prior to use will reduce the potential for IMS to be transferred into the area and ensure the management of these risks are **ALARP**. Environmental benefit outweighs additional cost.	Yes
In compliance with the National Biofouling Management Guidance for the Petroleum Production and Exploration Industry, a biofouling risk assessment will be completed for each vessel entering Australian territorial seas prior to mobilising to the OA.	P = Yes E = Effective	Biofouling risk assessments show low risk of IMS presence prior to entry into Australian waters. For vessels determined to have a moderate or high risk, the vessel contractor will need to engage a qualified independent third-party marine pest inspector to determine the corrective actions to reduce the vessel IMS risk to low. The vessel contractor must demonstrate to TGS that all corrective actions have been implemented and reassessment of the vessel prior to mobilisation determines the risk to be low. Environmental benefit outweighs additional cost.	Yes
Reporting of sightings or suspicions of any IMS on vessel/s, in niche areas or in ports/harbours.	P = Yes E = Effective	Reporting of any sighted or suspected IMS will allow an effective response to the presence of IMS and reduce the risk of further establishment of that species. Therefore, if an IMS is sighted or suspected, TGS will report by email to: • SA waters: Fishwatch Hotline (1800 065 522); • Agriculture VIC – marine.pests@agriculturevic.gov.au; and • Biosecurity TAS – biosecurity.tasmania@nre.tas.gov.au Notification will include photos of any sighted or suspected IMS. Notification will be provided no later than 24 hours following sighting/suspicion of the IMS. Environmental benefit outweighs additional cost.	Yes
Vessels to maintain a Biofouling Record Book.	P = Yes E = Effective	The National Biofouling Management Guidance for the Petroleum Production and Exploration Industry recommends vessels operators maintain a Biofouling Record Book to record details of all inspections and biofouling management measures undertaken on the vessel. Environmental benefit outweighs additional cost.	Yes
Reassessment of risks in the event of a change to contracted vessels.	P = Yes E = Effective	Under the NOPSEMA Information Paper 'Reducing marine pest biosecurity risks through good practice biofouling management', any change in risk profile because of new information or changes to the offshore activity should trigger a risk review process. If there is a change to the vessels contracted for the Otway Basin 3D MC MSS, a risk review process will be triggered to determine whether new or modified control measures should be adopted. Any new vessel contracted for the Otway Basin 3D MC MSS will comply with the appropriate Control Measures for minimising the risk of IMS. Environmental benefit outweighs additional cost.	Yes

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Alternative/Substitute Controls Considered:			
No discharge of ballast water from vessels during the Otway Basin 3D MC MSS.	P = No Effective = Partly effective	Although ballast water exchange is not expected to occur during routine survey activities, the possibility of needing to discharge ballast water cannot be ruled out completely and exchange and uptake may be required in unexpected circumstances where discharge/exchange is necessary to ensure the safety of persons onboard the vessel. Ballast water will already be managed in accordance with the Australian Ballast Water Management Requirements and as such, the likelihood of introducing IMS via ballast water is highly unlikely. This control measure is not practicable to implement and is disproportionate to any reduction in risk.	No
Additional Control Measures Considered:			
Mandatory dry docking of the Seismic Vessel prior to entering the OA.	P = No E = Effective	Although this control measure would eliminate IMS, the substantial costs associated with this occurring, in addition to the significant delays in the scheduling, make this control measure unsustainable; especially considering the other controls in place are expected to effectively reduce the risks associated with IMS. The cost associated with this measure would outweigh the reduction in risk.	No
Ballast the vessel using only finely filtered water or freshwater.	P = No E = Partly Effective	Ballast water requirements change frequently and supplying the required large volumes of finely filtered seawater, or freshwater is either not possible quickly enough, or would require large redesign of vessel/s to create enough storage. Making freshwater, and/or filtering seawater requires a large amount of energy, decreasing efficiency and sustainability. Therefore, the costs are disproportionate to benefits. Additionally, the allocation of freshwater, which likely has many other beneficial uses, to a commercial industrial application is not sustainable and should be minimised wherever possible. Using 'local' water as ballast provides an effective means of reducing IMS introductions to **ALARP**.	No
Treatment of ballast water, either through heat treatment or chemical dosage.	P = No E = Partly Effective	This control measure would reduce the potential for IMS to establish within the ballast water; however, the high cost involved in completing this control outweighs the reduction in risk, considering the other controls in place already reducing the risks associated with IMS. This type of control also includes detrimental effects to the marine environment, either through additional chemicals being released which are toxic to marine species, or high temperature water being added to the marine environment that may cause death of native marine species.	No
Source Seismic Vessel within Australia.	P = No E = Partly Effective	There is still a risk of an undetected IMS being present on/near the vessel at its Australian Port, as ports and marinas within the coastal nearshore marine environment are highly susceptible to IMS incursion and establishment. Additional time and resources would be required to find and assess suitable vessels within Australia, if any are present and available. Therefore, the costs are disproportionate to benefits.	No
Niche areas and deployed equipment built/redesigned to reduce IMS attachment or stowage.	P = No E = Effective	Design of vessels, niche areas and the seismic equipment make them as efficient as possible at their task. Additional redesign adds significant cost and may decrease the efficiency of equipment for its intended purpose, such as affecting the performance of sensitive equipment. Therefore, costs are disproportionate to benefits.	No
Residual Risk of Impact (Receptor)	**Consequence**	**Likelihood**	**Risk Ranking**
All receptors (outlined in **Section 8.1.2** and **8.1.3**).	Severe	Remote	Low
ALARP Statement:			
The decision context has been assessed as Type A and the overall residual risk has been determined to Low. TGS considers the adopted control measures minimise the risk of impacts from the introduction of IMS and are appropriate to the localised nature and small scale of the predicted environmental impacts associated with the Otway Basin 3D MC MSS. The proposed control measures have been developed in accordance with the legislative requirements, good industry practice, using professional experience and taking into account the specific environmental, social, economic and cultural characteristics of the OA and predicted impacts to other marine users. Additional control measures were considered as part of the assessment process; however, it was considered that they did not provide any further environmental benefit or were not reasonably practicable to implement. Therefore, the predicted impacts to receptors from the introduction of IMS are reduced to **ALARP.**			

8.1.6 Impact and Risk Acceptability

Table 108 Demonstration of General Impact and Risk Acceptability for the Introduction of Invasive Marine Species

Criteria for Acceptance	Acceptability Summary
Residual Risk Ranking	The residual risk has been determined to be Low.
Ecologically Sustainable Development	The management of the risks and impacts proposed by TGS associated with the introduction of IMS can be carried out in compliance with the five principles of ecologically sustainable development as defined within the EPBC Act. These principles have been considered as part of the development of this EP and risk assessment process. The assessment has not identified any adverse impacts to the principles of ESD, with no threats of serious or irreversible damage, no impacts to biological diversity and ecological integrity, no degradation of inter-generational equity, or negative effects on the social and economic integrity in the short or long-term. Therefore, the impact and risks are considered to be consistent with the principles of ESD.
TGS Internal Context	The proposed management of the risks associated with the establishment of IMS is consistent with TGSs QHSE Policy commitments of: • Protecting the environment; and • Conducting operations in an environmentally sustainable and responsible manner.
Existing Environmental Context	As described in **Section 8.1.2**, the greatest potential for an IMS introduction occurs due the movement and docking of vessels, and transporting material between contrasting sources and receiving environments. With regard to the Otway Basin 3D MC MSS, this would be limited to occurrences when the survey vessels visit ports/harbours at the beginning and conclusion of the campaign (noting that refuelling and re-supply will be conducted at sea). During acquisition of the survey, the vessels will be continually moving in offshore areas which make the potential attachment or translocation of IMS less likely. It is considered that the control measures in place will provide appropriate protection to the existing marine environment, and that the potential for any impacts and associated risks from the introduction of IMS are at an **Acceptable Level**.
External Context – Management Plans, Species Recovery Plans and Conservation Advice	The residual risk of the introduction of IMS has been determined to be Low and will not have a significant impact on a matter of national environmental significance in accordance with EPBC Act Policy Statement 1.1. The South-east Marine Parks Network Management Plan 2013 – 2023 allows for ballast water to be discharged or exchanged, except for within areas characterised as Sanctuary Zone (1A), subject to compliance with: • The Australian Ballast Water Management Requirements and relevant state ballast water management arrangements; • Relevant Commonwealth and state legislation or international agreements (if any) relating to ballast water management; and • Relevant prohibitions, restrictions and determinations made by the Director under the South-east Marine parks Network Management Plan. The control measures that will be implemented during the Otway Basin 3D MC MSS will be in accordance with MARPOL and are therefore consistent with the South-west Marine Parks Network Management Plan 2013 - 2023. Except for the Wildlife Conservation Plan for Seabirds 2022, review and assessment of the species recovery plans, and conservation advice did not identify threats associated with the establishment of IMS for the species of relevance to the OA (**Section 4.5.8**). Control measures that will be implemented for the Otway Basin 3D MC MSS to reduce the risk of IMS focus on the prevention of the introduction of IMS and are therefore consistent with the activities prescribed within the Wildlife Conservation Plan for Seabirds 2022 and species survival will not be compromised.
Social Acceptance – Relevant Persons Expectations	Commercial abalone fishers raised concerns regarding the introduction of fish disease as a result of vessel movements associated with the Otway Basin 3D MC MSS. TGS will implement strict biosecurity control measures to prevent the introduction of IMS, including fish disease. Therefore the environmental impacts relating to IMS and biosecurity during the Otway Basin 3D MC MSS are considered to be at a socially **Acceptable Level.**
External Context – Commonwealth and State Legislative Criteria	The proposed control measures for IMS introduction and establishment during the Otway Basin 3D MC MSS are consistent with the following relevant standards/documents: • Biosecurity Act 2015; • Australian Ballast Water Management Requirements (Version 8); • Australian Biofouling Management Requirements (Version 1); and • Protection of Sea (Harmful Anti-Fouling Systems) Act 2006.
Industry Best Practice	The control measures are based on industry best practice to decrease the risk of IMS introduction/establishment, including: • The IAGC Environmental Manual for Worldwide Geophysical Operations. This manual recommends ballast water management plans need to be in place and followed to ensure IMS are not translocated between regions/countries, including recommendations to regularly exchange ballast water, clean ballast tanks, etc.; • The APPEA Code of Environmental Practice, which recommends that geophysical surveys should have an environmental objective to reduce the risk of IMS introduction to **ALARP** and **Acceptable Levels**, including having evidence of appropriate quarantine management measures; • The National Biofouling Management Guidance for the Petroleum Production and Exploration Industry including the completion of an IMS risk assessment prior to the vessels entering Australian waters and in-water survey equipment being cleaned and dried prior to use in the OA;

Criteria for Acceptance	Acceptability Summary
	• IMO Guidelines for the Control and Management of Ships' Biofouling to Minimize the Transfer of Invasive Aquatic Species; and • Anti-fouling and In-Water Cleaning Guidelines.
ALARP	Complete elimination of the risk of IMS is not possible as the Otway Basin 3D MC MSS will require the use of vessels and deployed equipment which could be subject to biofouling, and ballast water will be required for each vessel to operate safely and efficiently. Following the implementation of the control measures detailed in this assessment, the residual risks and impacts to the marine environment and associated receptors from establishment of IMS is **Low**. In accordance with the Risk Ranking descriptions, the predicted magnitude of impact is acceptable without further reduction measures being required, the control measures are consistent with good industry practice have been applied and have been assumed in the design process. No further development of control measures is required if ALARP. It is considered that through the implementation of control measures, the potential for impacts and associated risks from the introduction of IMS, as a result of the Otway Basin 3D MC MSS, are at an **Acceptable Level**.

Acceptability Statement
Impacts and risks classified as 'Type A' are considered acceptable if the requirements in **Table 51** can be demonstrated and it can be determined that the predicted levels of impact and/or residual risk are at or below pre-defined Acceptable Levels for that impact or risk, including those described in **Table 52.** Based on the above evaluation, the potential impacts and risk from the introduction of IMS meets the requirements of the risk acceptability criteria. The control measures that will be implemented throughout the Otway Basin 3D MC MSS have been developed in accordance with these criteria and are considered appropriate to manage the impacts of the introduction of IMS on all receptors to an **Acceptable Level.**

8.1.7 Environmental Performance

Table 109 Environmental Performance Outcomes, Standards and Measurement Criteria for Invasive Marine Species

Number	Environmental Performance Outcome	Environmental Performance Standard(s)
EPO 24	No introduction or establishment of any Invasive Marine Species as a result of the Otway Basin 3D MC MSS	**EPS 207** to **EPS 228**

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
The Otway Basin 3D MC MSS will be undertaken in accordance with the approved EP.	**EPS 207**: The Otway Basin 3D MC MSS may only commence following acceptance of the EP by NOPSEMA.	Pre-mobilisation audit and inspection are completed prior to operations and confirm an accepted EP has been obtained. Audit records verify compliance with the requirements of the EP.	TGS VOM EA
	EPS 208: The Otway Basin 3D MC MSS will be undertaken in accordance with the accepted EP.	Bridge logs verify compliance with the requirements of the EP. Audit records verify compliance with the requirements of the EP.	TGS VOM VOC EA Vessel Master SEA
Adherence to the Australian Ballast Water Management Requirements (Version 8). Vessels will manage ballast water exchange/discharge using one of the following approved methods of management: • An approved ballast water management system; • Ballast water exchange conducted in an acceptable area (as defined in the Ballast Water Management Requirements (Version8)); • Use of low-risk ballast water (such as fresh potable water, high seas water or fresh water from an on-board fresh water production facility); • Retention of high-risk ballast water on board the vessel; or • Discharge to an approved ballast water reception facility.	**EPS 209**: Survey vessels will be compliant with the Australian Ballast Water Management Requirements (Version 8) by following at least one of the approved methods of management, including: • An approved ballast water management system; • Ballast water exchange conducted in an acceptable area (as defined in the Ballast Water Management Requirements (Version8)); • Use of low-risk ballast water (such as fresh potable water, high seas water or fresh water from an on-board fresh water production facility); • Retention of high-risk ballast water on board the vessel; or • Discharge to an approved ballast water reception facility.	Pre-mobilisation inspection/audit confirms at least one approved method is in place.	VOC TGS VOM Vessel Master Party Chief SEA CSR
	EPS 210: Ballast water discharges must comply with the relevant requirements of the Biosecurity Act 2015 and Australian Ballast Water Management Requirements (Version 8).	All Ballast Water exchanges recorded in Ballast Water Logbook. Biosecurity Clearance attained following Pre-Arrival Report process.	Vessel Master Party Chief SEA
	EPS 211: Internationally sourced ballast water will not be discharged within 12 NM of the nearest land or in water <50 m deep and preferably beyond 200 NM from nearest land in water >200 m deep.		

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
In accordance with the Ballast Water Management Requirements (Version 8), vessels will not exchange ballast water within 12 NM from the nearest land and in water depths of less than 50 m unless sourced from Australian waters.	**EPS 212**: Ballast waters sourced from Australian waters may be discharged within 12 NM of emergent land or in water <50 m deep (including ports/harbours).		CSR
Vessels will have a Ballast Water Management Plan in place and valid Ballast Water Management Certificate (unless an exemption applies or is obtained from (DoCCEEW).	**EPS 213**: A Ballast Water Management Plan will be maintained in accordance with Regulation B-1 of the International Convention for the Control and Management of Ships' Ballast Water and Sediments	Pre-mobilisation inspection/audit confirms each vessel holds an approved Ballast Water Management Plan.	Vessel Master Party Chief SEA CSR
	EPS 214: Vessels undertaking the Otway Basin 3D MC MSS will hold valid Ballast Water Management Certificates.	Pre-mobilisation inspection/audit confirms each vessel holds a valid Ballast Water Management Certificate.	VOC Vessel Master Party Chief
All vessels will maintain a complete and accurate Ballast Water Record System that is consistent with the Ballast Water Management Requirements (Version8).	**EPS 215**: A complete and current record of all ballast water movements will be maintained in the Ballast Water Record System to confirm ballast water management is undertaken in accordance with the Australian Ballast Water Management Requirements (Version 8).	Accurate and complete Ballast Water Record System kept onboard the vessel and maintained throughout the Otway Basin 3D MC MSS. Pre-mobilisation inspection/audit confirms each vessel has a Ballast Water Record System consistent with the Ballast Water Management Requirements (Version 8).	Vessel Master Party Chief SEA CSR
Vessels entering Australian territorial waters will obtain all the necessary DAFF biosecurity approvals, prior to mobilisation.	**EPS 216**: Operators of all vessels utilised during the Otway Basin 3D MC MSS will provide information on how biofouling has been managed prior to arriving in Australian territorial seas through the Pre-Arrival Report. Pre-Arrival Report is to be submitted through the DAFF Maritime Arrivals Reporting System between 96 – 12 hours prior to the estimated time of arrival.	Pre-mobilisation inspection/audit confirms each vessel has a copy of Biosecurity Status Document onboard each vessel following Pre-Arrival Report process	VOC Vessel Master SEA CSR
All vessels utilised for the Otway Basin 3D MC MSS will hold a valid Ship Sanitation Control Certificate or Ship Sanitation Control Exemption Certificate.	**EPS 217**: All vessels utilised during the Otway Basin 3D MC MSS will hold a valid Ship Sanitation Control Certificate or Ship Sanitation Control Exemption Certificate for the duration of the survey.	Pre-mobilisation inspection/audit confirms each vessel has a copy of valid Ship Sanitation Control Certificate or Ship Sanitation Control Exemption Certificate onboard each vessel	VOC Vessel Master Party Chief
All vessels utilised for the Seismic Survey will demonstrate proactive management of biofouling prior to entering Australian territorial waters by implementing one of the following three accepted proactive biofouling management options: • Implementation of an effective biofouling management plan; • Cleaned all biofouling within 30 days prior to arriving in Australian territory; or • Implementation of an alternative biofouling management method pre-approved by DoCCEEW.	**EPS 218:** As part of the Pre-Arrival Report referenced in **EPS 216**, each vessel will demonstrate proactive management of biofouling in accordance with the Australian Biofouling Management Requirements (Version 1). This can be achieved by implementing one of the following three accepted proactive biofouling management options: • Implementation of an effective biofouling management plan; • Cleaned all biofouling within 30 days prior to arriving in Australian territory; or • Implementation of an alternative biofouling management method pre-approved by DAWE.	Each vessel used for the Otway Basin 3D MC MSS will demonstrate proactive management of biofouling through the Pre-Arrival Report. Pre-mobilisation inspection/audit confirms each vessel proactively manages biofouling by ensuring a copy of Biosecurity Status Document is onboard each vessel following Pre-Arrival Report process.	VOC Vessel Master Party Chief

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
Effective anti-fouling systems and management practices are adopted for each vessel that complies with the requirements of Annex 1 of the International Convention on the Control of Harmful Anti-Fouling Systems on Ships and the requirements of the protection of the Sea (Harmful Antifouling Systems) Act 2006. Anti-foul systems used on the vessel will not consist of harmful anti-fouling compounds (i.e. an organotin compound that acts as a biocide in an anti-fouling system, or cybutryne) or each harmful anti-fouling compound that is applied on external surfaces has a coating that forms a barrier to the compound leaching into the water, or, for a ship that has cybutryne applied on a designated external surface, neither of the following has occurred; i) the first scheduled renewal of the ships' anti-fouling system after 1 January 2023, ii) the day that is 60 months after the last application of cybutryne to the ship before 1 January 2023.	**EPS 219**: A current international anti-fouling system certificate will be carried by each vessel associated with the Seismic Survey which shows that the vessel anti-fouling systems are maintained in accordance with the Protection of the Sea (Harmful Anti-fouling Systems) Act 2006 and Anti-fouling and In-Water Cleaning Guidelines which implements the International Convention on the Control of Harmful Anti-fouling Systems on Ships.	Pre-mobilisation inspection/audit confirms the Seismic Vessels are carrying a current International Anti-fouling System Certificate.	VOC Vessel Master Party Chief
	EPS 220: All vessels will comply with the requirements of the National Biofouling Management Guidance for the Petroleum Production and Exploration Industry (Commonwealth of Australia, 2009) which requires: • Maintenance of biofouling electronic records outlining marine fouling management actions • Completion of an IMS risk assessment prior to vessel entry into Australian waters and which concludes a low risk of IMS presence • In-water equipment free of marine fouling prior to the commencement of the survey	Pre-mobilisation inspection/audit confirms records are available to verify the following has occurred: • Marine fouling management actions are recorded electronically; • An IMS risk assessment has been completed prior to each vessel entry into Australian waters and concludes a low risk of IMS presence; and • In-water equipment is free of marine fouling prior to the commencement of the Otway Basin 3D MC MSS.	VOC Vessel Master Party Chief
All vessels will have 'clean' hull and niche areas upon arrival with a written report from a qualified marine biologist on the biofouling inspection. A Marine Biofouling Inspector will be contracted in accordance with the requirements set out in **Section 10.3.1** to ensure this.	**EPS 221**: Vessel will have had recent dry-docking or IMS hull inspection with appropriate certification and have a written report from a qualified marine biologist on the biofouling inspection.	Pre-mobilisation inspection/audit for IMS inspection certificate, dry-dock and/or anti-fouling application certification and written report from qualified marine biologist on the biofouling inspection.	VOC Vessel Master Party Chief
	EPS 222: A Marine Biofouling Inspector will be contracted in accordance with the requirements set out in **Section 10.3.1** to evaluate the risk profile of the survey vessel/s. When assessing the risk profile of the survey vessel/s, the Marine Biofouling Inspector will take into consideration the following (note that this is not an exhaustive list): • The age, type and condition of the vessel and anti-fouling coating; • Previous biofouling cleaning and inspections that have been undertaken on the vessel/s and the outcomes of these previous inspections; • An assessment of internal niches with potential to harbour IMS and presence and condition of internal seawater treatment systems; • The vessel's history since the last inspection, including the origin of the vessel and its potential for exposure to IMS and subsequent translocation risk; • An assessment of the vessel's Biofouling Management Plan and record book against the IMO Biofouling Guidelines; and • In-water inspections where appropriate.	Pre-mobilisation inspection/audit confirms a Marine Biofouling Inspector has been contracted for a biofouling assessment on vessels entering Australian territorial waters. Pre-mobilisation inspection/audit confirms documentation of biofouling assessment carried out on vessels entering Australian territorial waters.	VOC Vessel Master Party Chief

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
Survey equipment to be inspected, cleaned, and dried prior to deployment in the OA or Australian territorial waters.	**EPS 223**: All equipment deployed from vessel (e.g. streamers, birds, tail-floats, etc.) must be thoroughly cleaned, and then dried for at least 24 hours prior to being deployed in the OA or Australian territorial waters for the first time. This is consistent with the requirements of the National Biofouling Guidelines for the Petroleum Production and Exploration Industry.	Equipment maintenance records confirm that in-water equipment is free of marine fouling prior to survey commencement. Onboard records of equipment maintenance and cleaning.	Vessel Master Party Chief
In compliance with the National Biofouling Management Guidance for the Petroleum Production and Exploration Industry, a biofouling risk assessment will be completed for each vessel entering Australian territorial seas prior to mobilising to the OA.	**EPS 224**: Biofouling risk assessment is completed for each vessel before entering Australian territorial seas prior to mobilising to the OA.	IMS risk assessment has been completed prior to the vessel's entry into Australia and the risk has been determined as low.	TGS VOM VOC Vessel Master
Reporting of sightings or suspicions of any IMS on vessel/s, in niche areas or in ports/harbours.	**EPS 225**: Suspected or confirmed presence of any marine pests or disease must be reported to authorities within 24 hours of sighting, including photos of the suspected or confirmed marine pests or disease. Reports are to be provided to: • South Australia: Fishwatch Hotline (1800 065 522); • Agriculture VIC – marine.pests@agriculturevic.gov.au; and • Biosecurity TAS – biosecurity.tasmania@nre.tas.gov.au	Incident reporting form identifying sighting or suspicion of any IMS. Records of communication show report of suspected or confirmed presence within 24 hours by email or telephone.	Vessel Master. Party Chief. General Vessel Crew.
Vessels to maintain a Biofouling Record Book.	**EPS 226**: Each survey vessel shall maintain a Biofouling Record Book detailing all inspections and biofouling management measures undertaken on that vessel.	Biofouling Record Book maintained on each vessel. Pre-mobilisation inspection/audit confirms Biofouling Record Book is in place	Vessel Master Party Chief SEA CSR
	EPS 227: Biofouling Record Book will follow the format provided in Appendix B of the National Biofouling Management Guidance for the Petroleum Production and Exploration Industry.	Biofouling Record Book maintained on each vessel. Pre-mobilisation inspection/audit confirms Biofouling Record Book is in place	Vessel Master Party Chief SEA CSR
Reassessment of risks in the event of a change to contracted vessels.	**EPS 228**: A risk assessment will be carried out as per the Management of Change process in the event that there is a change in vessels part way through the Otway Basin 3D MC MSS.	Management of Change records show changed contracted vessel complies with biosecurity requirements listed in the EPSs above.	Vessel Master SEA CSR TGS VOM

8.1.8 Introduction of Invasive Marine Species Impact and Risk Summary

Based on the assessment above, including the identification of potential impacts on the environment and the associated controls measures to be implemented, the residual risk of the introduction/establishment of an IMS from the Otway Basin 3D MC MSS is considered to be **Low**.

The suite of control measures to be implemented have been developed in accordance with industry best practice, and all relevant legislation. Consequently, it is considered that the environmental impacts and risks on the marine environment and receptors arising from the introduction/establishment of an IMS from the Otway Basin 3D MC MSS Survey, are reduced to **ALARP**.

In accordance with the acceptability requirements prescribed in **Section 6.4,** the suite of control measures is considered appropriate to manage the risks and impacts arising from the introduction/establishment of an IMS from the Otway Basin 3D MC MSS on all receptors to an **Acceptable Level.**

8.2 Streamer Loss

8.2.1 Description of Source of the Impacts and Risks

There are a number of ways in which potential damage to and resultant loss of streamers could occur; these include snagging with floating debris, rupture from abrasions or shark bites, loss from severance during a collision (e.g. if another vessel were to accidentally cross the streamer), or a failure of lifting equipment. Solid streamers, such as those proposed to be used during the Otway Basin 3D MC MSS, are negatively buoyant and would sink if severed.

Impacts associated with the accidental loss of solid wastes (hazardous or non-hazardous) are assessed in **Section 8.5.**

8.2.2 Evaluation of Known and Potential Impacts and Risks to Environmental Receptors

Using the information presented in **Section 4** to **Section 5**, the impact and risk assessment has been undertaken for those receptors determined to be relevant to the activity as listed in **Table 110**.

Table 110 Environmental Receptors Assessed

Receptor	Section reference
Benthic habitats (banks, shoals and reefs)	**Section 8.2.2**
Benthic invertebrates	

Direct contact between the streamer and the seabed due to damage or loss would result in physical damage to the benthic habitat and any sensitive communities in the area. Should this equipment be irretrievably lost and persist on the seabed as debris, it has the potential to entangle with marine fauna or fishing equipment.

The OA is expected to be sparsely covered by macroalgae, sessile filter feeders, mobile macroinvertebrates and bioturbating infauna (Hosack and Dambacher, 2012; Williams *et al*., 2009). Several areas overlap the OA that support a high diversity of benthic assemblages, namely the Apollo and Zeehan AMPs (**Section 4.4.1** and the West Tasmanian Canyons KEF (**Section 4.4.3**). While it is possible that a lost streamer could cause physical damage to sensitive benthic communities within these areas and the wider OA, the control measures implemented throughout the duration of the Otway Basin 3D MC MSS will reduce the risk of equipment loss and subsequent environmental impact and ensure that the integrity of sensitive receptors (including AMPs and KEFs) will be maintained throughout the survey. Given the size of equipment used for the survey, only a relatively small area of the seabed would be disturbed, and lasting impacts are not expected.

Various control measures will be implemented during the Otway Basin 3D MC MSS (**Table 113**), including, but not limited to, the utilisation of solid streamers, integration of self-recovery devices and recording real-time positioning of the streamers, all of which are implemented to prevent the loss of streamer should it break free and stop it from reaching the seabed.

The 'streamer recovery devices' are pressure activated self-inflating buoys, that activate if a streamer is severed and sinks to a certain depth. This system provides sufficient positive buoyancy to return the damaged streamer to the sea surface, enabling recovery by the Support Vessel. Only solid streamers will be used during the Otway Basin 3D MC MSS. In contrast to oil-filled streamers and other alternatives, solid streamers do not contain fluids which could leak into the marine environment following damage or loss.

In the unlikely event that a streamer does contact the seabed, it is useful to note that areas of archaeological interest or cultural significance are typically associated with intertidal and shallow subtidal environments of the nearshore and costal marine environment. The nature of the OA, which is located offshore, affords low potential for impacts on such values. Additionally, it is considered that should the control measures fail, and a streamer is lost to the seabed, it would sink relatively quickly, before travelling any great distance. Therefore, if a streamer reached the seabed, it would be unlikely to drift beyond the boundary of the OA.

The residual risk to environmental receptors arising from the use of streamers during the Otway Basin 3D MC MSS has been assessed as **Low** (*Minor x Remote*).

8.2.3 Evaluation of Known and Potential Impacts and Risks to Other Marine Users

Using the information presented in **Section 4** to **Section 5**, the impact and risk assessment has been undertaken for those receptors determined to be relevant to the activity as listed in **Table 111**.

Table 111 Relevant Persons and Other Marine Users Assessed

Receptor	Section reference
Commercial Fisheries	**Section 8.2.3**
Shipping	
Oil and Gas Activities	
Submarine Cables	
Defence Activities	

In the unlikely event that equipment is lost, other marine users of the OA may be required to make minor diversions to avoid the equipment, until it can be retrieved (if possible). The potential for such interactions will be limited to a short period of time while the equipment is retrieved. Should disruption occur it is only expected to affect individual users and cause temporary disruption through avoidance of a highly localised area. Given the nature and size of the equipment to be used during the Otway Basin 3D MC MSS, lost equipment may result in a minor navigational hazard.

The residual risk to relevant persons and other marine users arising from the use of streamers during the Otway Basin 3D MC MSS has been assessed as **Low** (*Minor x Remote*).

8.2.4 Decision Context

The decision context for streamer loss has been assessed as Type A given the predicted impacts and risks are well understood and uncertainty is minimal, with little or no interest from relevant persons.

8.2.5 Identification of Control Measures, Residual Risk Assessment and Demonstration of ALARP

The control measures that have been considered during the Otway Basin 3D MC MSS to manage any potential impacts from the loss of a seismic streamer to **ALARP** have been included in **Table 113**. TGS has considered a number of control measures to assess the benefits of their implementation towards risk reduction (**Table 113**), based on a Hierarchy of Controls methodology (**Table 112**). The control measures that will be adopted are those that have been assessed and characterised as effective and practicable to implement.

Table 112 Hierarchy of Control Measures for Streamer Loss

Eliminate	The survey cannot be conducted without the use of streamers.
Substitute	There are no practicable substitutes for using streamers on the Seismic Vessel.
Reduce	Streamer recovery devices will float a lost/broken streamer, or section of streamer, to facilitate recovery by either of the survey vessels before it can make contact with the seabed. The streamer and associated towing equipment will be inspected and maintained for wear-and-tear and any worn or 'tired' parts replaced.
Mitigate	Control measures have been assessed within **Table 113** in order to mitigate the impacts from loss of a streamer to **ALARP** levels. Those which are appropriate and are not impracticable or unfeasible due to disproportionately large costs will be implemented during the Otway Basin 3D MC MSS.

Table 113 Assessment of Control Measures for Streamer Loss

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Legislative Requirements:			
The Otway Basin 3D MC MSS will be undertaken in accordance with the approved EP.	P = Yes E = Effective	All vessels undertaking an offshore activity in waters between 3 and 200 NM must undertake that activity in line with an approved EP. The approved EP outlines the measures that will be taken to ensure that environmental effects from the activity will be reduced to **ALARP** and **Acceptable Levels**, including the management of streamer loss.	Yes
Good Industry Practice:			
Solid streamers will be utilised for the Otway Basin 3D MC MSS and fitted with the following equipment: • Self-inflating streamer recovery devices (**SRD**s); • Depth control 'birds'; • Surface marker buoys; • Secondary retaining devices; and • Tail buoys.	P = Yes E = Effective	The utilisation of solid streamers which contain no fluids eliminates the risk that release of hazardous substances into the marine environment following damage or loss. SRDs will be fitted at nominated intervals along the streamer and programmed to automatically deploy at water depths that are shallower than the depth of the ocean where seismic data acquisition is occurring. Under typical conditions, this will allow a damaged and/or severed streamer to return to the sea surface, and be retrieved, before impacting the seabed. Depth control birds will allow the Seismic Vessel to control the depth of the streamers. This will ensure streamers do not sink too low in the water column and potentially impact the seabed, or migrate too deep and activate streamer recovery devices, which could add additional strain on the streamer while underway and making way. Environmental benefit outweighs additional cost.	Yes
Use of redundant attachment points to Seismic Vessel.	P = Yes E = Effective	Streamers will be attached to the Seismic Vessel via the main attachment point as well as a redundant attachment point. Redundant attachment points are a secondary attachment point that act as back-up in the event that the primary attachment point fails. Good industry practice, environmental benefit outweighs additional cost.	Yes
At least one Support Vessel will accompany the Seismic Vessel at all times and, if necessary and safe to do so, will assist in the recovery of lost equipment.	P = Yes E = Effective	At least one Support Vessel will accompany the Seismic Vessel for the duration of the Otway Basin 3D MC MSS. The aim of this vessel is to intercept any other marine users that may interact with the Seismic Vessel and towed equipment, identify and remove any fishing equipment that may be in the path of the Seismic Vessel, and be involved in the retrieval of lost equipment if required and safe to do so. Lost equipment will be located and recovered where safe and practicable to do so, in accordance with the Vessel Contractor's Non-Routine Equipment Recovery Procedures. Good industry practice, safety benefit outweighs additional cost.	Yes
Real time positioning of streamers.	P = Yes E = Effective	The exact position of the streamers will be monitored at all times utilising Intrinsic Ranging by Modulated Acoustics, allowing their positions to be seen relative to any potential hazards. Environmental benefit outweighs additional cost.	Yes
Adherence to vessel Standard Operation Procedure (**SOP**) for streamer deployment and retrieval at all times.	P = Yes E = Effective	All crew will be suitably familiar with and adhere to SOP documents relating to the preparation, deployment, operation and recovery of the seismic equipment to reduce risk of streamer damage and potential loss. SOPs also ensure that deployment and retrieval is undertaken in a safe and consistent manner. Environmental benefit outweighs additional cost.	Yes
All lifting gear used for deployment and retrieval of equipment over the vessel is load rated for the working load.	P = Yes E = Effective	All lifting gear used for the deployment and retrieval of equipment over the vessel will be load rated for the working load to ensure equipment is capable of lifting the loads required and minimise the risk of equipment failing. Environmental benefit outweighs additional cost.	Yes

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Inspections and maintenance of streamers and associated equipment.	P = Yes E = Effective	Inspections and maintenance of streamers and associated equipment (e.g. cables and attachment points) ensures that any 'wear-and-tear' is identified and fixed, reducing the potential for the breaking (and subsequent loss) of equipment. All in-sea equipment will be electronically monitored for performance and integrity during the course of the survey. Visual inspections will be carried out on any occasion the equipment is deployed or retrieved. Preventative maintenance will be carried out as per the vessels' Preventative Maintenance System. Environmental benefit outweighs additional cost.	Yes
Reporting of all incidents of lost equipment. AMSA JRCC, and other marine users in the EP Area, will be notified in the event of equipment loss.	P = Yes E = Effective	The recording and reporting of incidents, including those associated with lost equipment is standard in the industry. AMSA JRCC and other marine users of the OA will be notified in the event of equipment loss. Environmental benefit outweighs additional cost.	Yes
Alternatives/Substitutes Controls Considered:			
Alternative data acquisition method.	P = No E = Effective	The Otway Basin 3D MC MSS cannot acquire seismic data without the use of streamers and its associated equipment. Implementation of this control measure would render the survey inoperable.	No
Additional Control Measures Considered:			
Laying the streamers on the sea floor, also known as ocean bottom cable, as opposed to towing the streamers.	P = No E = Effective	Using this methodology for the Otway Basin 3D MC MSS would effectively eliminate the risk associated with the potential loss of a streamer, but it still requires an acoustic source to be towed behind a Seismic Vessel. Deploying the recording array on the seabed takes significantly more time and will introduce additional costs and extended timeframes. It will also cause temporary disturbance to the seabed. The costs would be prohibitively expensive and impracticable for a survey of this size. The proposed methodology is the most efficient way of conducting the survey in the shortest amount of time and will reduce the time that the Seismic Vessel is in the area.	No
Residual Risk of Impact (Receptor)	**Consequence**	**Likelihood**	**Risk Ranking**
Benthic habitats (banks, shoals and reefs)	Minor	Remote	Low
Benthic invertebrates	Minor	Remote	Low
Commercial fisheries	Minor	Remote	Low
Shipping	Minor	Remote	Low
Oil and gas activities	Minor	Remote	Low
Submarine cables	Minor	Remote	Low
Defence activities	Minor	Remote	Low
ALARP Statement			
The decision context has been assessed as Type A and the overall residual risk has been determined to Low. TGS considers the adopted control measures minimise the risk of impacts from streamer loss and are appropriate to the localised nature and small scale of the predicted environmental impacts associated with the Otway Basin 3D MC MSS. The proposed control measures have been developed in accordance with good industry practice, using professional experience and taking into account the specific environmental, social, economic and cultural characteristics of the OA and predicted impacts to other marine users. Additional control measures were considered as part of the assessment process; however, it was considered that they did not provide any further environmental benefit or were not reasonably practicable to implement. Therefore, the predicted impacts to receptors from streamer loss are reduced to **ALARP.**			

8.2.6 Impact and Risk Acceptability

Table 114 Demonstration of General Impact and Risk Acceptability for Streamer Loss

Criteria for Acceptance	Acceptability Summary
Residual Risk Ranking	The residual risk has been determined to be Low.
Ecologically Sustainable Development	The management of the risk associated with streamer loss can be carried out in compliance with the five principles of ESD as defined within the EPBC Act. These principles have been considered as part of the development of this EP and risk assessment process. The assessment has not identified any adverse impacts to the principles of ESD, with no threats of serious or irreversible damage, no impacts to biological diversity and ecological integrity, no degradation of inter-generational equity, or negative effects on the social and economic integrity in the short or long-term.
TGS Internal Context	The proposed management of the risks of streamer loss and its associated impacts will be informed by TGS's Non-Routine Equipment Recovery Procedures and Environmental and QHSE Policy commitments of: • Protecting the environment; and • Conducting operations in an environmentally sustainable and responsible manner
Existing Environmental Context	Of relevance, are the maintenance of management objectives and values for protected areas such as the Zeehan and Nelson AMPs and the West Tasmanian Canyons KEF which overlap OA. While it is possible that a lost streamer reaching the seabed could cause physical damage to benthic habitats and communities comprising the KEF and AMPs, the implementation of the proposed control measures ensure that the risks and potential impacts associated with the loss of a streamer do not impede the maintenance of management objective or values for protected areas. As a result, the risks and potential impacts associated with the loss of a streamer to these sensitivities is considered Low. It is considered that the proposed control measures provide appropriate protection to the existing marine environment from the risk of a lost streamer and that any associated effects (e.g. physical seabed damage) are at an **Acceptable Level**.
External Context – Management Plans, Species Recovery Plans and Conservation Advice	The residual risk of streamer loss has been determined to be Low and will not have a significant impact on a matter of national environmental significance in accordance with EPBC Act Policy Statement 1.1. **Section 4.5.8** provides an outline of the EPBC Act Conservation Management Plans, Recovery Plans and Conservation Advice relevant to the Otway Basin 3D MC MSS. Within these documents, the risk of marine debris impacting those relevant species is highlighted, with the actions required including supporting the implementation of the EPBC Act in accordance with the *Threat Abatement Plan for the impacts of marine debris on vertebrate marine life* (Commonwealth of Australia, 2018). TGS has reduced and, where possible, eliminated any adverse impacts of marine debris from the activities of the Otway Basin 3D MC MSS on turtles, cetaceans, sharks, and birds, noting the linkages with the *Threat Abatement Plan for the impacts of marine debris on vertebrate marine life.* While the OA overlaps the Zeehan and Nelson AMPs, management of loss of equipment will be consistent with the management prescriptions of the AMPs, Special Purpose Zones, and Multiple Use Zones. No impacts are predicted to occur to the natural , cultural, and socio-economic values of the AMPs. The NOPSEMA guidance note for petroleum activities and Australian Marine Parks (NOPSEMA guidance note N-04750-GN 1785 A620236) requires that an EP is developed for undertaking activities such as MSSs. The EP evaluates how environmental impacts and risks will be of an **Acceptable Level** and reduced to **ALARP** and demonstrates that the Seismic Survey will not be inconsistent with the relevant marine park management plan. Operations within the park must ensure the long-term maintenance of biodiversity and other natural values within the reserve. Although the OA is not located within any AMP, the proposed control measures in place to reduce the risk of streamer loss and subsequent environmental impact to adjacent AMP and will ensure that the integrity of the IUCN reserve management principles will be maintained throughout the survey.
Social Acceptance – Relevant Person Expectations	No concerns were raised in regard to possible impacts associated with the loss of a streamer, and as such no additional control/mitigation measures were expected or put in place as a result. The environmental impacts relating to the loss of a streamer from the Otway Basin 3D MC MSS are considered to be at a socially **Acceptable Level**.
External Context – Commonwealth and State Legislative Criteria	There are no relevant legislative requirements identified for the management of the risks and impacts from the potential loss of equipment (i.e. a streamer).
Industry Best Practice	The control measures to decrease the risk of streamer loss follow industry best practice and best practice guidelines and include: • The IAGC Environmental Manual for Worldwide Geophysical Operations, which recommends that operators: - Document and communicate their contingency plans for retrieving any equipment to help mitigate environmental impacts associated with the loss of that equipment; - Notify appropriate regulatory agencies in event of equipment loss; and - Make a reasonable effort to retrieve lost equipment as soon as possible after loss occurs. • The APPEA Code of Environmental Practice, which recommends that geophysical surveys should have an environmental objective to reduce the impacts from loss of equipment to **ALARP** and **Acceptable Levels**, including having evidence of appropriate management procedures and an emergency response plan.
ALARP	Streamers must be towed behind the Seismic Vessel during the Otway Basin 3C MD MSS, therefore total elimination of all impact associated with a streamer loss cannot be achieved. There are also no practicable alternatives. Following the implementation of control measures, the potential impacts to the marine environment and associated receptors from a loss of streamer are likely to be highly localised and short-term. Based on the assessment provided within this EP, the residual impact and risk of the loss of a streamer from the Otway Basin 3D MS MSS is considered to be **Low** and to **ALARP**. Therefore, the potential impact and risk from a lost streamer during the Otway Basin 3D MC MSS is considered to be at an **Acceptable Level**.

Acceptability Statement
Impacts and risks classified as 'Type A' are considered acceptable if the requirements in **Table 51** can be demonstrated and it can be determined that the predicted levels of impact and/or residual risk are at or below pre-defined Acceptable Levels for that impact or risk, including those described in **Table 52.** Based on the above evaluation, the potential impacts from streamer loss meets the requirements of the risk acceptability criteria. The control measures that will be implemented throughout the Otway Basin 3D MC MSS have been developed in accordance with these criteria and are considered appropriate to manage the impacts of streamer loss to an **Acceptable Level.**

8.2.7 Environmental Performance

Table 115 Environmental Performance Outcomes Standards and Measurement Criteria for Streamer Loss

Number	Environmental Performance Outcome	Environmental Performance Standard(s)
EPO 25	No loss of equipment to the marine environment.	**EPS 229** to **EPS 243**

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
The Otway Basin 3D MC MSS will be undertaken in accordance with the approved EP.	**EPS 229**: The Otway Basin 3D MC MSS may only commence following acceptance of the EP by NOPSEMA. Incident report/record shows the loss of the streamer and communications sent to relevant persons on the location of the equipment.	Vessel Master Party Chief SEA CSR EA
	EPS 242: AMSA will be notified of any lost equipment as soon as practicable, as a potential navigation hazard.	Incident report/record shows the loss of the streamer and communications sent to AMSA on the location of the equipment.	EA
	EPS 243: Any complaints received regarding loss of equipment will be recorded in a complaint register.	Complaints register will outline any complaints received.	TGS VOM

8.2.8 Streamer Loss Impact and Risk Summary

Based on the discussions above, including the potential impacts on the environment and the associated controls measures to be implemented, the residual risk of the loss of a streamer from the Seismic Vessel is considered to be **Low**.

The suite of control measures to be implemented have been developed in accordance with industry best practice. Consequently, it is considered that the environmental impacts and risks on the marine environment and receptors arising from streamer loss during the Otway Basin 3D MC MSS, are reduced to **ALARP**.

In accordance with the acceptability requirements prescribed in **Section 6.4,** the suite of control measures is considered appropriate to manage the risks and impacts arising from the loss of a streamer during the Otway Basin 3D MC MSS on all receptors to an **Acceptable Level**.

8.3 Vessel Collision, Sinking, and Bunkering and Associated Hydrocarbon Spills

8.3.1 Description of Source of the Impacts and Risks

In 2011, AMSA commissioned a study to estimate the risk of pollution from marine oil spills in Australian ports and waters (DNV, 2011). Part of this study assessed the breakdown of spills by accident type as a frequency per year; this assessment found that spill frequencies are dominated by drift grounding (21.6%), transfer spill (19.9%) and powered grounding (19.1%); whereas the frequency of a collision causing a spill is 11.6%.

The Seismic Vessel will be operating in deep offshore waters, with the vast majority of the survey lines being in waters 100 – 5,000 m, or beyond the shelf edge. As outlined in **Section 3.5.5**, bunkering of the survey vessels will be undertaken at sea. Whilst this activity is recognised as a potential source of risk for a hydrocarbon spill during the Otway Basin 3D MC MSS, the control measures and mitigating factors ensure that this risk, and magnitude of potential adverse effects, are small and any effects are restricted to well within the footprint of the OA. Given it is a source of risk, however, this is assessed alongside the risk of vessel collision for the purpose of this EP. The most catastrophic and hence 'worst-case' scenario for a spill occurrence is that associated with a vessel collision/sinking.

A collision between the survey vessels and another vessel (e.g. passing merchant vessels, fishing vessels, passenger vessels, etc.) has the potential to cause widespread environmental impacts. The most significant potential environmental impact associated with vessel collision is related to the vessel/s sinking and making contact with the sea floor, or damage to the vessel/s and associated release of on-board hazardous substances, specifically the oil, fuel and lubricants, and the effects of these substances on the marine and coastal environment. A surface release of hydrocarbons from a vessel collision or sinking has the potential to result in ecological impacts on various environmental receptors through surface, dissolved and entrained hydrocarbon exposure.

The very worst-case scenario for a hydrocarbon spill would likely arise where the entire contents of either of the survey vessel's fuel tanks were released into the surrounding ocean. However, compartmentalised fuel storage systems will be on the vessels to be utilised during the Otway Basin 3D MC MSS, which effectively reduce the volume of a spill that could occur if the vessel was damaged. In addition, onboard emergency procedures include transferring contents of a ruptured tank into other tanks, where possible.

A collision at sea is unlikely due to routine seagoing procedures undertaken by the crew and master (in accordance with COLREGs), the slow speeds at which the survey vessels will be operating (4 – 5 knots), notifications issued to other marine users (i.e. Notice to Mariners), as well as state of the art navigational systems (i.e. transmitting and receiving AIS and radar) which are typically found on Seismic Vessels, and which support the seismic data acquisition.

For bunkering of marine diesel between the Support Vessel/s and the Seismic Vessel within the OA, two scenarios for a hydrocarbon spill include:

- Loss of containment of marine diesel during bunkering operations, such as a partial or total failure of a bulk transfer hose or fittings during bunkering. This failure may be caused by mechanical stress/integrity issues that could spill marine diesel to the deck and/or into the marine environment. This is estimated to be in the order of less than 200 L, based on the likely volume of a bulk transfer hose (assuming a failure of the dry break and complete loss of hose volume); and

- Partial or total failure of a bulk transfer hose or fittings during bunkering, combined with a failure in procedure to shutoff fuel pumps, for a period of up to five minutes, resulting in approximately 8 m^3 marine diesel loss to the deck and/or into the marine environment.

8.3.2 Oil Spill Trajectory Modelling

TGS has commissioned an assessment of the oceanic dispersal and beaching potential in the unlikely event of a spill resulting from vessel collision during the Otway Basin 3D MC MSS (RPS 2023, see full report in **Appendix C**). In the assessment, a stochastic approach has been adopted to define the statistical probabilities related to oil trajectory, dispersion, diffusion, weathering, and beaching patterns. This was achieved by simulating the occurrence of 100 realistic spill events of MDO from five locations within the OA, randomly distributed over the previous decade with a continuous release of 1,066 m^3 of MDO over six hours at sea level.

For this EP, the scenario of a hydrocarbon spill associated with bunkering was not included in the modelling outputs, however information from other EPs is presented to provide an indication of the likely extent of effects that could occur from such spills. The relatively small volume of any spill associated with a bunkering operation is small by comparison to the worst-case scenarios adopted for the trajectory modelling for vessel collision. Any spill associated with bunkering would be small, contained within the OA, and based on the fate and transport of MDO in the offshore environment, effects would be very localised around the site of the spill and would not persist for very long.

8.3.2.1 Methodology

Spill modelling was conducted at five release locations, which were selected based on their proximity to shorelines and sensitive receptors (**Figure 85**, see **Appendix C** for full report). Release Location 1 is 40 km from the nearest shoreline, Release Location 2 ~38 km, Release Location 3 ~58 km, Release Location 4 ~53 km, and Release Location 5 ~52 km.

Modelling of the trajectory and fate of oil was performed using the Spill Impact Mapping and Assessment Programme (**SIMAP**). This model is designed to simulate the transport and weathering processes that affect the outcomes of hydrocarbon spills to the sea, accounting for the specific oil type, spill scenario, and prevailing wind and current circulation patterns. The SIMAP model calculates two components as follows:

- The transport, spreading, entrainment, evaporation, and decay of surface oil slicks; and
- The entrained and dissolved hydrocarbons released from the slicks into the water column.

Physico-chemical characteristics of the selected oil type detailing the input specifications include the density, viscosity, pour point, distillation curve (volume lost versus temperature) and the aromatic/aliphatic component ratios within given boiling point ranges.

The fuel for the Seismic Vessel will be MDO, which compared with marine gas oil, has lesser environmental persistence following a spill event. Despite its lower persistence, a conservative approach has been retained for the study.

MDO has specific and well documented characteristics which influence its persistence in the marine environment after a spill event; overall it is classified as a Group II, Light persistent Oil. Physical characteristics are described as:

- Density of 829.1 kg/m3 at 15°C
- Dynamic viscosity of 4.0 cP at 25°C,

- Pour Point -14°C;
- High percentage (95%) volatiles (will evaporate when on the sea surface);
- Contains 5% persistent hydrocarbons (do not evaporate or breakdown over time); and
- Relatively high natural dispersion in breaking wave conditions and poor natural dispersion in non-breaking wave (swell) conditions.

The characteristics of MDO is that oil will quickly disperse under wave action but tends to persist as a surface slick during calm weather. On the sea surface, strong winds will increase the rate of evaporation, while the wave conditions associated with these winds also act to mix and disperse the oil into the upper layers of the ocean. Consequently, the day-to-day weather conditions strongly influence the mass budget of MDO throughout the simulations.

The SIMAP trajectory model separately calculates the movement and distribution of the hydrocarbon by mass into the following components:

- Surface-bound or floating oil;
- Entrained oil (non-dissolved oil droplets that are physically entrained by wave action);
- Dissolved hydrocarbons (principally the aromatic and short-chained aliphatic compounds);
- Evaporated hydrocarbons;
- Sedimented hydrocarbons; and
- Decayed hydrocarbons.

The model calculates the transport of surface slicks from the combined forces exerted by surface currents and wind acting on the oil. Transport of entrained oil (oil that is below the water surface) is calculated using the currents only.

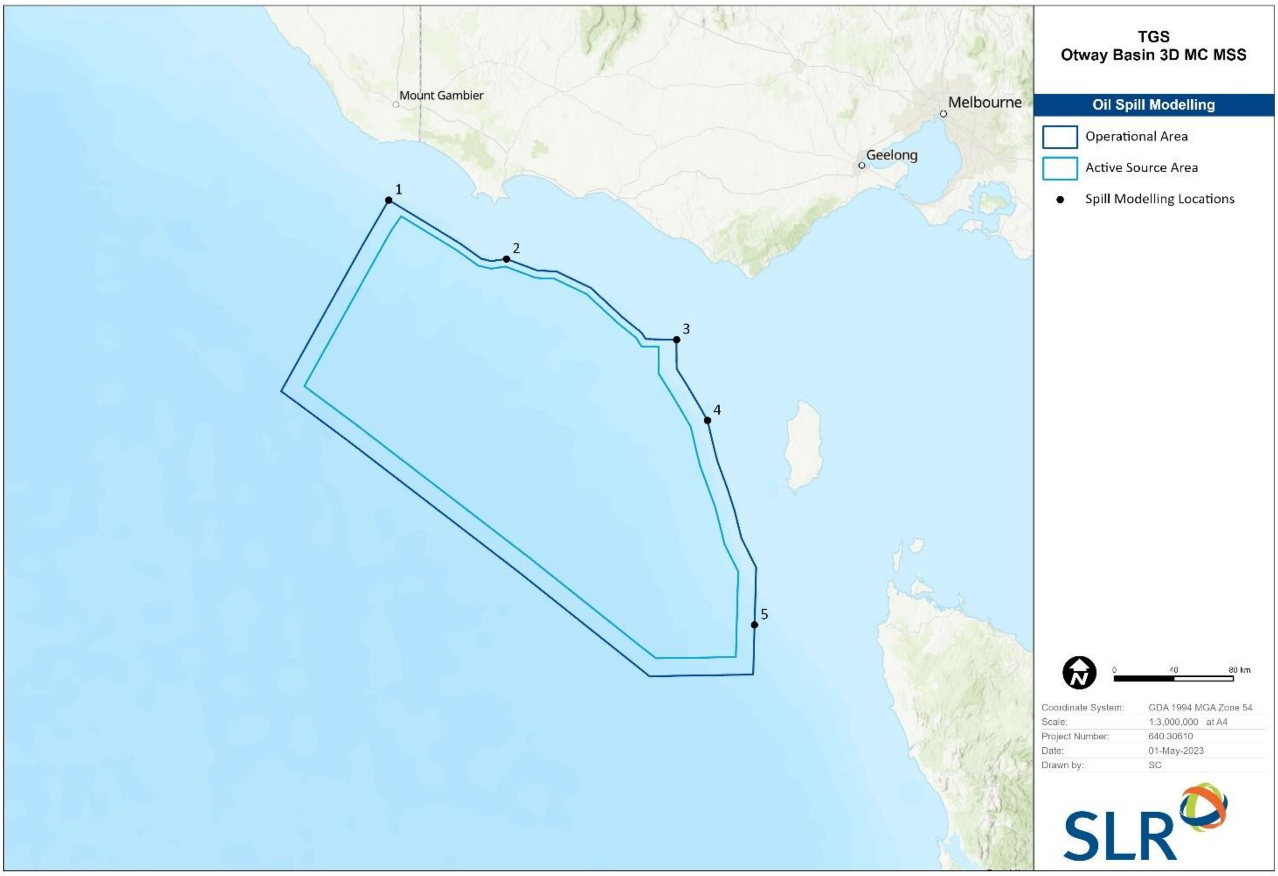

Figure 85 Position of the Five Spill Release Locations (1-5) Chosen Within the Otway Basin OA

The simulated spill scenario was a surface release of 1,066 m^3 of MDO over a six-hour period. Each spill was tracked by the model for 50 days, and the results used to form a database of 100 events (per release location, 500 in total) which were analysed to derive statistics on the fate and mass budgets, plus the probability of occurrence for specific impacts. The SIMAP includes algorithms to account for both physical transport and weathering processes, and for each simulation, records the location (by latitude, longitude and depth) of each of the oil mass units represented in the model. Thus, the simulation framework allows for the weathering dispersal and trajectory of the spill for a maximum exposure of hydrocarbons on the surface, entrained at water depths of 0 – 10 m and 10 – 20 m, dissolved in depths of 0 – 10 m and beaching to be modelled.

Records of historical hindcasts of the wind and ocean current conditions from 2010 – 2019 (inclusive) were used to drive the numerical model. Rose plots for the seasonal and annual conditions for winds and surface currents are presented in **Figure 86** and **Figure 87**. Modelling was conducted at any time of year to ensure weather and hydrodynamic conditions provide the worst-case extent of the hydrocarbon release scenario, ensuring conservatism in the modelling.

8.3.2.2 Exposure Values

The outputs of the hydrocarbon spill modelling are used to assess the environmental risk, if a credible hydrocarbon spill scenario occurred, by defining which areas of the marine environment could be exposed to hydrocarbon levels exceeding exposure values that may result in impact to sensitive receptors. Different exposure levels therefore influence the exposure type, and therefore the assessment of risk as follows:

- Surface hydrocarbon exposure levels, to assess physical effects on sensitive receptors offshore;
- Shoreline accumulation levels, to assess physical effects on sensitive receptors onshore; and
- Water column exposure levels, to assess toxicity effects to sensitive receptors offshore from entrained and dissolved aromatic hydrocarbons.

The degree of impact will depend on the sensitivity of the biota contacted, the duration of the contact (exposure) and the toxicity of the hydrocarbon mixture making the contact. The toxicity of a hydrocarbon will change over time, due to weathering processes altering the composition of the hydrocarbon.

The modelling considered four key physical or chemical phases of hydrocarbons that pose differing environmental and socio-economic risks: surface, entrained, dissolved and shoreline accumulated hydrocarbons. The modelling used pre-defined hydrocarbon exposure values, which have been identified as relevant for risk assessment and oil spill planning, for the various hydrocarbon phases. The pre-defined exposure values are listed in **Table 116**. These are based on the instantaneous exposure values defined in NOPSEMA Bulletin #1 Oil Spill Modelling (April 2019).

A review of available EPs identified that the potential extent of several small marine diesel spills has been modelled, including surface spill volumes of 8 m^3 in offshore waters of northwest Western Australia (Woodside, 2022; Woodside, 2021). This modelling showed elevated hydrocarbon concentrations are limited to the immediate vicinity of the spill site, with exposure to surface hydrocarbon concentrations above 10 g/m^2 predicted to occur within 1 km of the release point, with little potential to exceed this threshold beyond this distance. The 10 g/m^2 threshold representing concentration above which ecological impacts are expected to occur (being the ‘moderate’ threshold listed in **Table 116**).

Table 116 Summary of the Hydrocarbon Exposure Thresholds

Exposure Type	Potential Level of Exposure	Hydrocarbon Concentration	Description
Surface hydrocarbons (floating) (g/m^2)	Low	1	This value represents the area where a visible sheen may be present on the surface but is below concentrations at which ecological impacts are expected to occur. It is indicative of perceived impacts and areas that may be temporarily closed as a precautionary measure. It predicts the potential for some socio-economic impact (visual/aesthetic).
	Moderate	10	This represents the minimum oil thickness at which ecological impacts (e.g. to birds and marine mammals) are expected to occur. It is the lowest "actionable" level where spill response may be possible.
	High	50	This value is the estimated minimum floating hydrocarbon threshold for containment and recovery and informs response planning.
Total submerged hydrocarbons (entrained) (ppb)	Low	10	This value establishes the planning area for scientific monitoring based on potential for exceedance of water quality triggers.
	High	100	This represents potential toxic effects, particularly sublethal effects to sensitive species and life stages.
Dissolved hydrocarbons (ppb)	Low	10	This value establishes the planning area for scientific monitoring based on potential for exceedance of water quality triggers.
	Moderate	50	This represents potential toxic effects, particularly sublethal effects to highly sensitive species and life stages of fish and invertebrates (e.g. larvae, plankton).
	High	400	This value represents toxic effects including lethal effects to sensitive species.
Accumulated hydrocarbons (shoreline) (g/m^2)	Low	10	This value represents light oiling (equivalent to 2 teaspoons of oil per m^2). It is indicative of perceived impacts and shorelines that may be temporarily closed as a precautionary measure and predicts the potential for some socio-economic impact (visual/aesthetic).
	Moderate	100	This represents the minimum oil thickness at which potential lethal ecological impacts (e.g. to intertidal invertebrates, shorebirds, mammals and reptiles) may occur. It also predicts areas likely to require clean-up effort.
	High	1000	This value predicts areas likely to require intensive clean-up effort. Potential significant impacts to coastal vegetation including mangroves and marshes.

8.3.2.3 EMBA Definition

For the purposes of this EP, and for the assessment of the potential impacts and risks associated with the worst-case credible hydrocarbon spill of 1,066 m^3 within the OA, the EMBA has been defined based on:

- The maximum extent of shoreline accumulation above the low exposure level (10 g/m^2);
- The maximum extent of sea surface exposure above the low exposure level (1 g/m^2);
- The maximum extent of dissolved hydrocarbons above the low exposure level (10 ppb); and
- The maximum extent of the entrained hydrocarbons above the low exposure level (10 ppb).

The levels used to define the EMBA account for ecological impacts. However, the lower surface and shoreline exposure levels are also considered in the risk assessment in relation to perceived affects due to visible hydrocarbon sheens that may result in area closures of areas and potential socio-economic impacts.

8.3.2.4 Oil Spill Modelling Results

Section 8.3.2.4.1 to **Section 8.3.2.4.4** summarise the results for the oil spill scenarios, expressed as the maximum probability (across annual conditions) of exposure to individual sensitive receptors for each modelled release location.

In addition to the above, a separate request was made of RPS to provide maximum probability (across annual conditions) of exposure to BIAs within the EMBA. The full results of this can be found within Addendum 1 to the spill modelling report within **Appendix C**, with specific discussions around the relevant BIAs found throughout **Section 8.3.3.2**.

The results represent the total exposed area resulting from all 500 simulations at each release site over the total 50-day model duration. At any one point in time, the sea surface area exposed during an actual spill would be significantly smaller.

The results show that the fate of spilled MDO in the Otway Basin is highly dependent on seasonal patterns of surface currents (which are described as variable across spring to summer, and easter, northeast across autumn to winter), seasonal current speed/direction, and seasonal wind speed/direction. Modelling outcomes indicated spills travelled in a general east to southeast direction (**Table 117**)

8.3.2.4.1 Sea Surface Exposure

The maximum distance from a release site to low (1 – 10 g/m^2), moderate (10 – 50 g/m^2) and high (≥50 g/m^2) exposure levels were 243.2 km east (Release Location 1), 52.5 km east-southeast (Release Location 1) and 22.9 km south-southeast (Release Location 4), respectively (**Table 117**) (RPS 2023) and seen in **Figure 88**.

Table 117 Maximum Distances and Directions Travelled by Floating Oil for Each Exposure Threshold from an MDO Survey Vessel Tank Rupture at the Five Selected Release Locations

Release locations	Distance and direction	Zones of potential sea surface exposure		
		Low (1-10 g/m2)	Moderate (10-50 g/m2)	High (>50 g/m2)
1	Maximum distance from release site (km)	243.2	52.5	18.3
	Maximum distance from release site (km) (99th percentile)	176.6	50.1	17.6
	Direction	East	East-southeast	East-southeast
2	Maximum distance from release site (km)	141.5	44.5	21.8
	Maximum distance from release site (km) (99th percentile)	129	39.7	21.3
	Direction	East-southeast	South-southeast	East-southeast
3	Maximum distance from release site (km)	128.6	24.3	16.2
	Maximum distance from release site (km) (99th percentile)	111.2	22.6	15.1
	Direction	East-southeast	Southeast	East
4	Maximum distance from release site (km)	86.7	51.9	22.9
	Maximum distance from release site (km) (99th percentile)	74.2	49.1	19.6
	Direction	South-southeast	East-southeast	South-southeast
5	Maximum distance from release site (km)	140.8	30.0	15.4
	Maximum distance from release site (km) (99th percentile)	92.8	28.5	15.3
	Direction	East-southeast	East-southeast	East-southeast

Figure 88 Hydrocarbon Spill Scenario from Release Locations 1 – 5 for a 1,066 m^3 MDO spill – Potential Floating Oil Exposure

Table 118 provides a summary of the potential exposure from floating oil to sensitive receptors. Of particular interest includes exposure to AMPs at the low threshold was predicted for Release Location 3 (Apollo, 11%) and Release Location 4 (Zeehan, 65%). Twelve spill simulations (or 12% probability) had crossed into the VIC state waters from Release Location 1 at the low threshold. From Release Location 4, the probability of the spill simulations crossing the TAS and VIC state waters at the low threshold was 10% and 1%, respectively. The Discovery Bay and Twelve Apostles AMPs were exposed by 2 and 1 simulations (2% and 1% probability), respectively from Release Location 1 (RPS, 2023).

L= Low, M= Moderate, H= High

Results calculated from 100 spill trajectories (per site) during annual conditions and each simulation was based on a hypothetical 1,066 m3 surface release of MDO over six hours, tracked for 50 days.

8.3.2.4.2 Shoreline Exposure

Table 119 presents a summary of the predicted shoreline accumulation for the five selected release locations modelled from all 500 simulations. The probability of accumulation on any shoreline at, or above, the low threshold (≥ 10 g/m^2) was greatest at Release Location 5 (65%), while the minimum time before shoreline accumulation was 1.7 days at Release Location 1. The maximum volume of oil ashore for a single spill above the low threshold was greatest at Release Location 1 (126.5 m^3) and lowest at Release Location 2 (28.7 m^3). The maximum lengths of shoreline contacted at the low and moderate thresholds were 65.0 km (Release Location 5) and 15.0 km (Release Locations 1 and 4), respectively. Additionally, the maximum lengths of oil accumulation on shorelines at the high threshold (≥1,000 g/m^2) was 2 km recorded at Release Locations 1 and 4.

Table 120 lists the potential shoreline loading for the specified thresholds from all 500 simulations. Individual receptor exposures across the five separate release locations are listed in the full oil spill modelling report, and are summarised as follows (see RPS, 2023 in **Appendix C** for full details):

- The greatest probabilities of oil accumulation to shoreline sectors at the low threshold for a spill occurring was recorded at Corangamite (22%), Colac Otway (10%), King Island (9%), King Island (37%) and West Coast (42%) shorelines (Release Locations 1, 2, 3, 4 and 5, respectively);
- The King Island shoreline recorded the greatest probabilities of oil accumulation for the moderate and high thresholds from spills occurring at Release Location 4 (20% and 3%, respectively);
- Glenelg recorded the quickest time before oil accumulation at the low threshold at 1.67 days from a spill at Release Location 1; and
- The Glenelg shoreline was also predicted to experience the greatest peak volume ashore of 123.6 m^3 from a spill occurring at Release Location 1.

Table 119 Summary of Oil Accumulation on any Shoreline from an MDO Survey Vessel Tank Rupture for The Five Selected Release Locations Modelled

Shoreline Statistics	Location 1	Location 2	Location 3	Location 4	Location 5
Probability of accumulation on any shoreline (%) at or above the low threshold (10 g/m^2)	47	46	51	53	65
Absolute minimum time before oil ashore (days) at or above the low threshold (10 g/m^2)	1.7	6.8	3.5	3.4	3.2
Maximum volume of hydrocarbons ashore (m^3)	126.5	28.7	68.0	66.2	46.5
Average volume of hydrocarbons ashore (m^3)	12.1	2.9	2.9	7.2	3.8
Maximum length of the shoreline at 10 g/m^2 (km)	49.0	42.0	37.0	49.0	65.0
Average shoreline length at 10 g/m^2 (km)	18.5	13.7	11.5	18.5	20.4
Maximum length of the shoreline at 100 g/m^2 (km)	15.0	12.0	11.0	15.0	14.0
Average shoreline length at 100 g/m^2 (km)	7.2	4.7	4.6	6.8	5.0

Shoreline Statistics	Location 1	Location 2	Location 3	Location 4	Location 5
Maximum length of the shoreline at 1,000 g/m^2 (km)	2.0	-	1.0	2.0	-
Average shoreline length at 1,000 g/m^2 (km)	2.0	-	1.0	1.3	-

8.3.2.4.3 Water Column Exposure – Dissolved Hydrocarbons

Following a surface spill, hydrocarbons in the water column (at the surface, or deeper) can partition into a dissolved phase (dissolution of aromatic hydrocarbons into the water). Hydrocarbons that do not partition can remain entrained as homogenous oil droplets, suspended in the water column. Dissolved hydrocarbons represent the hydrocarbon phase with the main potential for toxicity effects, while entrained hydrocarbons have the potential for physical effects. Given their inherent relationship, the results of the modelling are discussed together.

Table 121 summarises the maximum dissolved hydrocarbon concentrations and probabilities of exposure to sensitive receptors in the 0 – 10 m depth layer from an MDO survey vessel tank rupture at the five selected release locations. **Figure 90** illustrates the extent of the dissolved hydrocarbon exposure in the 0 – 10m, depth layer, based on all 500 spill simulation.

Exposure of AMPs to the low threshold (≥10 ppb) was recorded at the Apollo (4% Location 2, 9% Release Location 3 and 2% Release Location 4%), Boags (1% Release Location 5), Franklin (5% Release Location 5) and Zeehan (1% Release Locations 2 and 3; and 29% Release Location 4) AMPs.

Exposure of Interim Biogeographic Regionalisation for Australia (**IBRA**) to the low threshold occurred at four sites from Release Location 1, and at one site (being King Island IBRA) for Release Locations 3, 4, and 5.

The greatest maximum instantaneous concentration (ppb) in the 0 – 10 m depth layer was predicted to occur within the Otway IMCRA at Release Location 2 (358 ppb). The Otway IMCRA was predicted to be exposed across all five scenario release locations, with predicted maximum concentrations ranging from 107 ppb – 358 ppb.

State Marine Parks were predicted to be exposed to low threshold dissolved hydrocarbons only from Release Location 1. No Ramsar sites were predicted to be exposed to dissolved hydrocarbons.

For State waters and Near Shore waters, three sites were predicted to be exposed to low threshold concentrations, one site for Release Locations 2 and 3, and two sites for Release Location 5. No State or Near sore waters were predicted to be exposed to medium or high threshold dissolved hydrocarbons.

There were generally a greater number of sensitive receptors predicted to be exposed to low threshold concentrations, compared with receptors predicted to be exposed to moderate thresholds. No receptors were predicted to be exposed to high thresholds of dissolved hydrocarbons (>400 ppb).

With increasing distance from the release location, most of the more volatile and more toxic hydrocarbons (i.e. aromatics) will have dissolved, therefore any remaining entrained oil will have comparatively reduced toxicity potential. Given dissolved and entrained hydrocarbons are predicted to be limited to the upper 20 m of the water column and principally within the upper 10 m, exposure of deeper offshore benthic habitats and communities not discussed in the scenario modelling is not predicted to occur.

Table 121 Maximum Dissolved Hydrocarbon Concentrations and Probabilities of Exposure To Sensitive Receptors in the 0 – 10 m Depth Layer From an MDO Survey Vessel Tank Rupture at the Five Selected Release Locations

Receptor		Release Location 1				Release Location 2				Release Location 3				Release Location 4				Release Location 5

Figure 90 Hydrocarbon Spill Scenario from Release Locations 1 – 5 for a 1,066 m^3 MDO spill – Potential Dissolved Hydrocarbon Exposure

8.3.2.4.4 Water Column Exposure – Entrained Hydrocarbons

Table 122 summarises the maximum entrained hydrocarbon concentrations and probabilities of exposure to sensitive receptors in the 0 – 10 m depth layer from an MDO survey vessel tank rupture at the five selected release locations.

Across all five Release Locations, a total of ten AMPs were predicted to be exposed at the low threshold (≥ 10 ppb), with probabilities up to 40%. The Apollo AMP was predicted to record the highest probabilities of exposure at 40% and 39% from spills originating from Release Location 3 and Release Location 1, respectively. Additionally, the Apollo AMP recorded the greatest probability of exposure at the high threshold (≥ 100 ppb) at 25% from spills originating from Release Location 3.

Otway IMCRA was exposed to high threshold across simulations from all five Release Locations. The maximum entrained hydrocarbon concentration was 30,878 ppb recorded for the Otway IMCRA from a spill originating at Release Location 3.

No state marine park, marine sanctuary, national park, National Parts Act (Schedule 4 park or reserve), Ramsar or reefs, shoals and banks sites were predicted to be exposed to high threshold across any of the simulations from the five Release Locations but were predicted to be exposed to a range of both low and high exposure thresholds (**Table 122**).

For State waters, VIC and TAS were exposed to high threshold concentrations of entrained hydrocarbons from Release Locations 1 and 4, respectively. For Nearshore waters, two sites were predicted to be exposed to high threshold concentrations, with the highest predicted concentration occurring at King Island Near shore waters (12,420 ppb, at 2% probability from Release Location 4). Glenelg Nearshore waters were predicted to be exposed to 1,059 ppb (with a 7% probability) from Release Location 1. As with other receptors, most nearshore waters were predicted to be exposed to variable low and high threshold concentrations across a range of probabilities.

Figure 91 illustrates the extent of the entrained hydrocarbon exposure in the 0 – 10 m layer, based on all 500 spill simulations.

Table 122 Maximum Entrained Hydrocarbon Concentrations and Probabilities of Exposure to Sensitive Receptors in the 0-10 m Depth Layer from an MDO Survey Vessel Tank Rupture at the Five Selected Release Locations

8.3.3 Evaluation of Known and Potential Impacts and Risk to Environmental Receptors

Using the information presented in **Section 4** to **Section 5**, the impact and risk assessment has been undertaken for those receptors determined to be relevant to the activity as listed in **Table 123**.

Table 123 Environmental Receptors Assessed

Receptor	Section reference
Marine environment quality (water and air quality)	**Section 8.3.3.1**
Benthic invertebrates	**Section 8.3.3.2.1**
Zooplankton, fish eggs and larvae	**Section 8.3.3.2.2**
Bony fish and elasmobranchs	**Section 8.3.3.2.3**
Marine reptiles	**Section 8.3.3.2.4**
Cetaceans	**Section 8.3.3.2.5**
Seabirds and migratory shorebirds	**Section 8.3.3.2.6**
Cultural and heritage sites	**Section 8.3.3.3**
Coastal marine environment	**Section 8.3.3.4**

Potential effects of a hydrocarbon spill on the marine environment will be influenced by factors such as the weather and sea conditions at the time (**Section 8.3.2**), the specific characteristics of the hydrocarbon fuel type, effectiveness of clean-up/response measures (**Table 126**) and the sensitivity of the environment and organisms that exist in the affected area (**Section 4**). Hydrocarbon spills will affect the water quality in the upper surface waters of the water column and can cause immediate/acute chemical and physical impacts to marine species, as well as longer term/chronic impacts such as bioaccumulation in the food chain and behavioural changes (e.g. predator/prey interactions).

The known effects of hydrocarbon spills on the marine environment are well documented and include, but are not limited to:

- Direct and indirect toxicity effects (e.g. Alonso-Alvarez *et al.,* 2007; Almeida *et al*., 2012; Schwacke *et al*., 2013);
- Removal and damage to, or exclusion from habitats and other important areas (Lee and Page, 1997);
- Bioaccumulation in the food chain, disruption of food chains and predator/prey interactions (e.g. Abbriano *et al.,* 2011; Ansari *et al.,* 2012; Wise *et al*., 2014);
- Loss of waterproofing, buoyancy, swimming ability, filtering capabilities, and thermoregulatory abilities from external oiling (especially in pinnipeds and seabirds) (e.g. Jenssen, 1994; O'Hara and Morandin, 2010); and
- Exclusion of users of the marine environment due to contamination/tainting of edible species or altered perception (e.g. Law and Hellou, 1999; McCrea-Strub *et al.,* 2011; Balcioglu, 2016).

Different hydrocarbon fuel types have different chemical characteristics which influence the fate if released into the receiving environment. The bulk of MDO spilled into the marine receiving environment will, over time, become dispersed, and undergo physical evaporation, with a component expected to become gradually submerged, and a low proportion potentially beached. Depending on location and prevalent weather conditions, the rate of other attenuation processes (dispersion, dilution, partitioning, beaching, biodegradation and photo-oxidation) will be affected.

Dissolved hydrocarbons are bioavailable and incur higher toxicity than entrained hydrocarbons. Dissolved hydrocarbons can be taken up by organisms directly from the water column by absorption through external surfaces and gills, as well as through the digestive tract (RPS, 2023). These bioavailable hydrocarbons are broken down by microbial decay and biodegradation. Biodegradation rates are relatively high for hydrocarbons in dissolved state or in dispersed small droplets.

Entrained hydrocarbons refer to the droplets of oil within the water column, these are not in the dissolved phase. The toxicity of entrained hydrocarbons is driven by the concentration of soluble aromatics (e.g. polycyclic aromatic hydrocarbons). Entrained hydrocarbons that are significantly weathered and have lost much of their soluble (aromatic) content comprise insoluble hydrocarbons that are less toxic but have the potential to persist and incur physical effects to marine organisms through direct contact with tissues of organisms (such as adhering to fish gills or filter feeding organisms) and uptake of oil droplets by direct consumption (RPS, 2023).

Entrained and dissolved hydrocarbons incur a range of physico-chemical responses at both chronic and acute toxicity levels, if a spill is left unmitigated. The risks of adverse effects are discussed in the following sections.

8.3.3.1 Potential Marine Environment Quality Impacts and Risks

A vessel collision has the potential to affect the local marine environment by impacting the surrounding water and air quality in the vicinity of the incident. In the highly unlikely event of a vessel collision/sinking these effects are predicted to be localised and temporary, and conditions will quickly return to background levels on account of weathering of spilled hydrocarbons, on-site response actions (if required), and in-water dilution effects.

Similarly, any release of hydrocarbon as a result of refuelling incident is, by comparison to a vessel collision, regarded as small and there will be negligible impacts on the physical marine environment. Given the small volume of release expected, any acute effects of a spill entering the marine waters are expected to be rapidly mitigated by immediate dilution and dispersion. On board control measures and operational contingencies are expected to minimise further release into the marine receiving environment (See **Section 8.3.5**).

A worst-case larger spill scenario along the northern extent in the OA could pose potentially longer-term impacts, given the increased likelihood of oil beaching. Oil beaching has the potential to interfere with sensitive receptors on near shore/intertidal areas, through habitat modification, or through the physical smothering/impairment of the animal itself (e.g. impairment of their feeding, respiratory and/or locomotory structures). The OA is located between ~38 km – ~82 km to the nearest shorelines (across VIC and TAS), with worst case oil spill modelling predicting a 46 to 65% chance of a section of the shoreline being affected by oil accumulation above the low threshold (see **Table 119**). Despite this, any potential hydrocarbon release is expected to undergo significant physical dispersion and dissolution, prior to any amount being beached. This is demonstrated for the 'worst case' spill scenario, whereby 11% of the modelled volume remained on the shoreline at the conclusion of the 50-day simulation (for a simulated release from Location 1), with the remainder lost to the atmosphere through evaporation (43%), decayed (38%), remaining on surface (<1%) or entrained (9%) (RPS 2023).

Localised seabed damage and disturbance could occur in the event that vessel debris makes contact with the seabed. Across much of the OA the seabed is likely to be composed of unconsolidated coarse carbonate sands (in shallower waters) to fine/muddy carbonate sands (in deeper waters) across the continental shelf area, and hard substrate across the inner shelf areas. Sinking debris would marginally disturb the seabed as it lands, with potential resuspension of finer-grained sediments.

Where possible, damaged vessels resulting from collision would be salvaged and returned to a suitable facility for repair or disposal, and smaller items of debris would be recovered.

Based on the above, the residual risk of a vessel collision and associated hydrocarbon spill on the physical marine environment has been assessed as **Low** (*minor* x *remote*).

The residual risk associated with refuelling and associated hydrocarbon release on the physical marine environment has been assessed as **Negligible** (*negligible* x *remote*).

8.3.3.2 Potential Biological Environment Impacts

Marine fauna in the open ocean areas of the OA is described as relatively mobile and are expected to be able to display avoidance behaviours in the event of any hydrocarbon release. By contrast, fauna (and flora) with less mobility that would not exhibit immediate behavioural response (e.g. plankton/primary producers, benthic species, early life stages (juveniles) of cephalopods and some vertebrate species), as well as benthic environments and coastal ecosystems could be at risk of being contacted by a hydrocarbon spill if a release event were to occur during a more sensitive life stage for the animal (i.e. seasonally depended), or on the southern extent of the OA whereby a higher probability of oil beaching may be incurred.

Potential adverse effects on the marine environment from marine debris released during a sinking event include entanglement and ingestion. Entangled individuals may drown, suffer from injury, or be subject to reduced foraging efficacy and/or predator avoidance. Ingestion of foreign debris is also a possibility which could lead to blocked digestive tracts, internal injury, and suppressed appetite (Laist, 1987). However, the majority of marine debris released through a vessel collision/sinking event would not be of the nature that would cause such effects (i.e. entanglement and ingestion is particularly problematic for plastics and discarded fishing gear), and the majority of such debris would likely remain contained within their collection receptacles onboard the vessel.

In the event of a vessel collision/sinking, the greatest impact to the biological environment will be associated with the release of hydrocarbons. Lighter oils, such as MDO, are significantly more toxic to marine organisms than heavy crude oils (NOAA, 2022), although lighter oils are less persistent in the marine environment due to evaporation of volatile components.

Environmental impacts from a spill following vessel collision/sinking in the marine environment will primarily be restricted to those species that inhabits the sea surface, mainly marine mammals, seabirds, and marine reptiles, although fish, cephalopods and zooplankton may also be impacted (at a chronic level) following dispersion and partitioning of any oil slick.

Any release of hydrocarbon as a result of refuelling incident is, by comparison to a vessel collision, regarded as small. The small volume of potential discharge would possibly impact the immediate surrounding water in the vicinity of the spill. Given the small volume of release expected, any acute effects of a spill entering the marine waters are expected to be rapidly mitigated by immediate dilution and dispersion – concentrations of concern would not be expected beyond a distance of around 1 km. On-board control measures and operational contingencies are expected to minimise further release into the marine receiving environment. Noting the OA covers waters deeper than 100 m, to reduce risks to sensitive surface water ecological values (which is they key area of concern for any oil spill event), TGS will not undertake refuelling at sea within 5 km of any AMP – these buffer areas are shown in **Figure 92**.

The 5 km buffer distance from these sensitive receptors is considered to be very conservative as the available literature suggests concentrations of concern are likely to be restricted to within 1 km of any likely spill during refuelling.

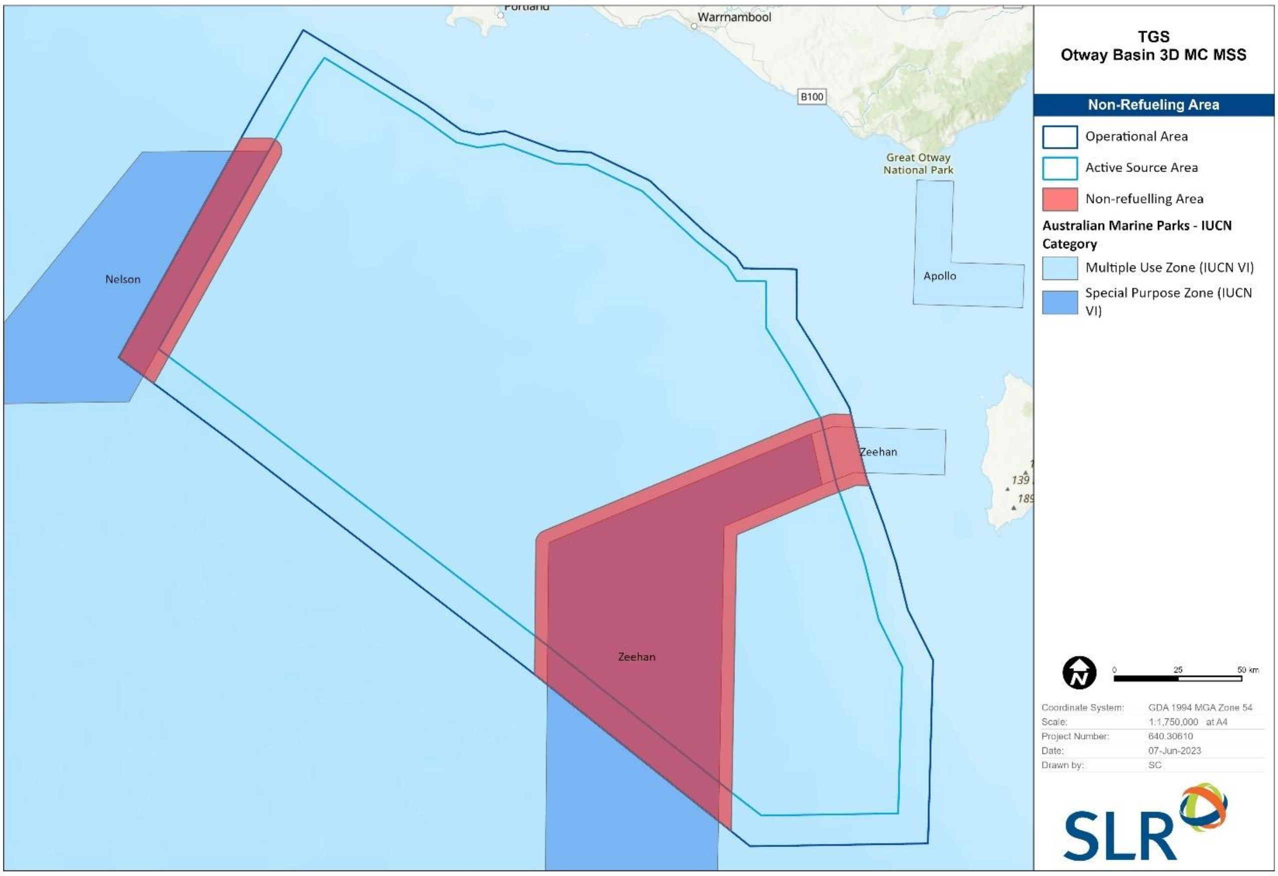

Figure 92 Proposed Non-Refuelling Areas

8.3.3.2.1 Benthic Invertebrates

A release of hydrocarbons under a worst-case scenario may impact benthic species under certain weather/spill conditions. Benthic invertebrate species likely to be present across the continental shelf may include sessile filter feeders (e.g. sponges, bryozoans, bivalves, scallops, stalk crinoids, soft corals), mobile macro-invertebrates (e.g. echinoderms, crustaceans) and bioturbating infauna (e.g. annelids) (see **Section 4.5.2**). The distribution of benthic invertebrates, however, is predominantly across deeper waters where the exposure to elevated hydrocarbon thresholds (exceeding the moderate thresholds of ecological concern) in waters deeper than 20 m is highly unlikely.

Sessile invertebrates across the continental shelf and species with low mobility (e.g. soft-sediment benthic invertebrates like echinoderms and crustaceans) may be susceptible to physical effects of vessel collision/sinking. Risk of exposure to any hydrocarbon release, however, is expected to be very low given the depth and expected dispersion/evaporation/dissolution of any spilled MDO into the marine receiving environment. Life history strategies (e.g., high fecundity, high recruitment) for many benthic invertebrates also ensures that if any adverse impacts are incurred, localised population resilience and recovery will be rapid.

The Otway Basin 3D MC MSS will be undertaken in waters ranging from 95 – 5,000 m in depth. This depth physically mitigates and attenuates any potential for direct oiling impacts on the benthic environment from a spill within the OA, given the spill plume will largely be buoyant in the surrounding ocean. Any oil beaching is more likely to incur potential direct acute and chronic effects to near shore/intertidal invertebrates if they come into direct contact with any beached MDO. This scenario is highly unlikely, and any effects are expected to be highly localised.

For marine invertebrates inhabiting nearshore or intertidal habitats, exposure to moderate threshold surface, dissolved, entrained or to beached oil poses potential impacts that may incur short term effects (i.e. impairment of behaviour, feeding, motility), or longer-term chronic effects (e.g. impaired growth and reduced fecundity). Behavioural and long-term chronic effects are generally incurred because of prolonged exposure, and a range of marine invertebrate species are not considered to be acutely sensitive to short-term elevations in oil concentrations (IPIECA, 2015).

One species of threatened seastar, the Tasmanian live-bearing seastar (*Parvulastra vivipara*) was identified within the EPBC Act Protected Matters Report as potentially present within the EMBA (see **Section 4.5.2**). The habitat is described as the upper intertidal zone of rocky shore areas of southeast TAS, which may be at risk of exposure to low thresholds (>10 ppb) of entrained hydrocarbons. Modelled distribution of shoreline accumulation of hydrocarbons indicated the southeast coast of TAS was not exposed to shoreline accumulation (rather, shoreline accumulation for TAS is a risk for the west coast).

Based on the predicted scenario modelling, exposure of nearshore/shallow water marine invertebrates to moderate threshold dissolved hydrocarbons is not likely to occur (see **Figure 90**). However, exposure of nearshore waters to entrained hydrocarbons may occur across some nearshore waters at the moderate threshold, as well as a low probability of exposure to high threshold levels (King Island). Any marine invertebrates exposed to moderate threshold entrained hydrocarbons may experience low level chronic effects, and exposure to high threshold may incur acute effects, though the probability of this is very low.

In the event of a spill close to the eastern edge of the OA (i.e. closest to TAS coastline), approximately 2% (26 m^3) of a worst-case oil spill was predicted to remain on the shoreline (after the 50 day simulation), present at levels exceeding either the low or medium exposure thresholds (RPS, 2023). The high exposure threshold was not predicted to be exceeded. Across the combined modelled outcomes, exposure to high range thresholds is only predicted across a subset of sites at King Island (TAS) and Portland (VIC), with correspondingly low probabilities of occurrence. The risk of exposure of resident marine invertebrate species to acute hydrocarbon concentrations, is thus also likely to be very low.

Based on the parameters of the proposed Otway Basin 3D MC MS, the control measures in place and the physical properties of the MDO if it is released in the marine environment, the potential for long-term impacts to benthic invertebrates from an MDO spill are very unlikely. The residual risk to benthic invertebrates arising from an accidental release of MDO as a result of a vessel collision/refuelling incident during the Otway Basin 3D MC MSS has been assessed as **Low** (*minor x remote*).

8.3.3.2.2 Zooplankton, Fish Eggs and Larvae

During and after an oil spill event, marine zooplankton, eggs, and larvae (as well as phytoplankton assemblages), may exposed to dissolved oil fractions and dispersed oil droplets. Several studies have demonstrated that plankton may take up dissolved petroleum hydrocarbons by passive mechanisms or consuming contaminated phytoplankton, as well as ingestion of oil droplets (Almeda *et al*., 2016). If dissolved fractions are high, acute toxicity thresholds may be incurred.

A hydrocarbon spill within the OA has the potential to overlap with two key areas (the Bonney Upwelling on the north-western extent of the EMBA, and the Tasmanian Canyon upwelling) identified as important for promoting high productivity. This is important for plankton distribution, in particular the coastal krill *Nyctiphanes australis*, a key contributing factor influencing aggregation of blue whales in the SEMR (see Section **4.5.1**).

A hydrocarbon spill within the OA also has the potential to overlap the Zeehan AMP – identified as a nursery ground for blue warehou and ocean perch (**Section 4.4.1**).

Depending on the time of year, in the event of an oil spill within the OA, larval stages of commercially targeted fish species (e.g. Blue warehou, blue grenadier, orange roughy, southern rock lobster, abalone, scallop and squid) may be affected. Larval stages of other important demersal and pelagic fish species, as well as macro-zooplankton assemblages (e.g. copepods and cladocerans) may also be impacted depending on the scale/location and timing of any oil spill event.

Across the extent of the EMBA, breeding areas of other fish may potentially be affected in the event of a large oil spill (e.g. up to 1,066 m^3). The northeastern extent of the EMBA is shown to intersect with the white shark breeding and foraging BIA (**Figure 21**), and nearshore waters identified as important habitats for smaller fish species such as pipefish are likely to also be important nursery habitats. Under a worst-case spill event, exposure to surface or entrained hydrocarbons may pose a risk of exposure to larval/egg stages present in any nearshore sensitive habitats. The probability of exposure exceeding the moderate or high thresholds (of ecological risk) are, however, low. Across the Zeehan AMP, the highest risk was identified for any accidental release of oil from Location 4 – resulting in a higher probability of acute toxicity thresholds across the AMP. Deterministic modelling, however, demonstrates that water column exposure to oil (via dissolved or entrained) will be a short duration, with the bulk of any volume lost though evaporation and degradation after 5 – 10 days (RPS, 2023).

Any hydrocarbon spill has the potential to reduce the water quality by increasing toxicity due to the presence of entrained/dissolved hydrocarbons, resulting in localised mortality of plankton due to potentially acute thresholds. Acute toxicity thresholds will be highest in areas close to the spill source. However, MDO is expected to rapidly evaporate and disperse/partition in the offshore marine environment, reducing the acute toxicity of the spill. Whilst localised mortality for zooplankton may occur, this is expected to be localised and short term. Due to their vertical stratification within the water column (eggs and larvae are generally not at the sea surface), eggs and larvae are less likely to come into direct contact with the bulk of any spill.

Planktonic communities impacted by a spill are expected to recover quickly (weeks/months) due to rapid fecundity and recruitment (ITOPF, 2011). The residual risk to plankton arising from an accidental release of MDO as a result of a vessel collision/refuelling incident during the Otway Basin 3D MC MSS has been assessed as **Low** (*minor x remote*).

8.3.3.2.3 Bony Fish and Elasmobranchs

The primary pathways to exposure for fish from a hydrocarbon spill are through direct dermal contact such as oiling of gills/smothering (Hook *et al*., 2016), and/or ingestion of contaminated prey.

Fish are also at risk from an MDO spill due to partitioning of dissolved hydrocarbons and any entrainment of hydrocarbons within the water column (leading to exposure through ingestion or dermal contact). This risk is reduced by the fact that adult fish have chemoreceptors – sensitive for detecting taste and smell, which can enable them to avoid the areas of a spill where there are hydrocarbons within the water column (NERA, 2018a).

Due to their mobility, it is unlikely that pelagic fish would be exposed to acutely toxic concentrations of spilled hydrocarbons for the extended periods of time required to result in acute toxicity to be incurred. NOAA (2012) and ITOPF (2011) have reported that deaths of adult fish are rarely observed from hydrocarbon spills in the open ocean due to the rapid dilution and evaporation.

The Otway Basin supports a diverse assemblage of fish, including three species of threatened fish within the OA, and five threatened and/or migratory species of sharks and rays which may be present within the OA. Within the EMBA there are 12 species of threatened fish and seven species of threatened elasmobranch (i.e. sharks, rays, and skates) identified within the EPBC Act Protected Matters Report (see **Section 4.5.3** for full details).

Several BIAs (important for foraging and migration) for grey nurse sharks were identified as overlapping the EMBA, up to 650 - 663 km NE of the OA. A BIA for the white shark was also identified as both overlapping the OA (distribution habitat), as well as breeding habitat overlapping the EMBA (at Corner Inlet, 285 km E of the OA).

Oil spill modelling (Addendum 1 to **Appendix C**) shows that, should a spill occur, both the white shark and grey nurse shark BIAs will be exposed in some way to the spilt hydrocarbons, a brief summary of these results are as follows:

- The grey nurse shark BIAs (both foraging and migration) will have a very low probability of being exposed to entrained hydrocarbons, with the greatest probability being 3% chance of being exposed to the low threshold from Release Location 2; and
- The white shark distribution BIA will be exposed to some extent due to its large spatial extent in relation to the OA. The white shark foraging BIA has a low chance of being exposed to both surface and dissolved hydrocarbons, but a higher chance of being exposed to entrained hydrocarbons, particularly from Release Location 1 (being a 25% probability of being exposed to the high threshold (>100 ppb). The white shark breeding BIA has, at most, a 6% chance of being exposed to the low threshold of entrained hydrocarbons from Release Location 3.

Information on the possible effects on sharks of an oil spill are largely unknown, but could have serious implications; for example, if a spill were to occur, the health of individual sharks, or the group as a whole, could be affected both directly through ingestion of oil and indirectly through disruption to food sources (DPAW, 2013). The risk for this to happen is however particularly higher for an oil spill containing crude oil than MDO that rapidly dilutes and evaporates in the water column.

Other species of sharks and rays could be present at low densities all year round within the OA and EMBA; however, the absence of any known feeding, resting or breeding areas means significant numbers are unlikely to be impacted if an unplanned release were to occur.

As the fish populations within the OA and EMBA are highly mobile pelagic species, it is unlikely that fish populations would be subjected to sufficient hydrocarbon contamination for periods long enough to result in mortality. Results of modelling demonstrate that there are no areas identified as exceeding the acute toxicity threshold of 400 ppb within the 0 – 20 m depth of water (the depth range likely to be exposed to dissolved fractions). Surface area exposed to moderate (50 ppb) are identified from Release Locations 1 to 5, but markedly decrease with increasing depth to 20 m. Predicted weathering and fate modelling shows that both dissolved and entrained hydrocarbons decrease rapidly within 3 – 5 days after release, with the bulk of spilled material being lost to evaporation and decay over time (RPS, 2023)

Fish populations are likely to be distributed over a wide geographical area so impacts on populations or species level are considered to be negligible. Combined with these factors and the rapid dispersion of marine diesel, the residual risk to fish species arising from an accidental release of MDO as a result of a vessel collision/refuelling incident during the Otway Basin 3D MC MSS has been assessed as **Low** (*minor x remote*).

8.3.3.2.4 Marine Reptiles

As summarised in **Section 4.5.5**, two species of endangered/migratory marine reptiles (loggerhead turtle, leatherback turtle), and three species of vulnerable/migratory marine reptile (green turtle, hawksbill turtle, flatback turtle) may be present within the EMBA.. No sea snake species were identified as potentially present.

The SEMR is not known to support breeding habitats for the turtle species identified in **Section 4.5.5**, and there are no BIAs for marine reptile species identified for the OA or EMBA, thus impacts to breeding habitat for marine turtles is not expected to occur.

Marine reptiles may be at risk from a hydrocarbon spill as they need to surface for breathing, and may be exposed to ingestion, inhalation and/or skin contact with hydrocarbons on the ocean surface. MDO has a low stickiness so it is unlikely to stick to turtles in large amounts and would likely wash of skin surfaces; however, MDO may cause skin irritation to sensitive organs such as eyes.

A hydrocarbon spill within the OA may result in impacts to individual marine turtles and a potential disruption to a portion of the foraging activities, however, this is not expected to result in a threat to the overall population viability due to the rapid dispersion of MDO. The residual risk to marine turtles arising from an accidental release of MDO as a result of a vessel collision/refuelling incident during the Otway Basin 3D MC MSS has been assessed as **Low** (*minor x remote*).

8.3.3.2.5 Marine Mammals

Marine mammals in the area could potentially ingest MDO when feeding in open water, or they could get coated with MDO when they surfaced to breath. However, given MDO has a low stickiness, it is likely that it would wash off the dorsal surfaces of cetaceans as they dived into deeper waters. MDO contact with sensitive body parts such as eyes may cause injury or damage and when cetaceans surface to breath, and there is the potential for volatile hydrocarbons to be inhaled. Hydrocarbons are fat-soluble and therefore tend to bioaccumulate before being eliminated by metabolism and excretion (Troisi *et al*., 2007). Physiological effects from internal contamination include dehydration, anaemia, organ damage, intestinal ulceration, immunosuppression, irritations and burns to mucous membranes (Balsiero *et al*., 2005). Cetaceans that spend extended periods of time at the sea surface will be particularly at risk to the effects of an MDO spill.

The north-eastern and north-western extent of the EMBA is shown to overlap areas identified as foraging BIAs for sperm and humpback whale. The overlap corresponds with the modelled entrained hydrocarbons in the low threshold range (10 ppb) with very low probabilities of occurring (3% chance for humpback foraging BIA and 1% chance for sperm whale foraging BIA), thus it is not expected to present either chronic or acutely toxic risks directly to these species, nor to their foraged food sources.

The pygmy blue whale distribution and foraging BIAs will be exposed in some way to hydrocarbons in the unlikely event of an oil spill. The foraging BIA has a high chance of being exposed to the high threshold of floating oil (50 g/m^2) from all Release Locations except 5, with the highest probability being 88% from Release Location 3. In terms of dissolved hydrocarbons, Release Location 4 is modelled to have the highest probably of the BIA being exposed to the moderate threshold (at 49%); however, the highest concentration was modelled at 358.1 ppb (below the high threshold of 400 ppb) from Release Location 2. The foraging BIA was modelled to have a high probably of exceeding the high entrained threshold (100 ppb) from each of the Release Locations.

The southern right whale breeding BIA was modelled to have a very low chance of exposure to the low threshold of entrained hydrocarbons, at 1% from Release Location 5, this not posing an ecotoxicological risk to biota. Other BIA features of the southern right whale (aggregation, migration, connecting habitat) may potentially be exposed to a range of hydrocarbon under worst -case spill scenarios. The duration of any such exposure is expected to be of minimal duration only (0.5 days maximum for surface exposure).

For Australian sea lions, foraging areas of the BIA are shown to overlap the EMBA (**Figure 26**). This overlap corresponds to a modelled exposure to entrained hydrocarbons up to a maximum of 106.4 ppb, thus not anticipated to pose a risk of chronic or acute direct (to the sea lions) or indirect (to food sources) toxicity.

For other marine mammals, species are expected to be present in the EMBA in low numbers and limited to isolated individuals or small pods. In the unlikely event of a spill occurring, they are not expected to remain in the vicinity of spilled hydrocarbons for extended periods. Although surface feeding cetaceans would be sensitive to a hydrocarbon spill, the residual risk of a vessel collision/refuelling incident and associated MDO spill on cetaceans has been assessed as **Low** (*minor x remote*) on account of their ability to metabolise hydrocarbons, low degree of adhesiveness of the MDO, and the fast dispersion and weathering of volatile hydrocarbons.

8.3.3.2.6 Seabirds and Migratory Shorebirds

Seabirds are susceptible to potential impacts at various exposure levels for surface oil through pathways such as a reduction in insulation and waterproofing, ingestion, impaired flight and navigation (AMSA, 2017). Depending on the length of time of exposure, especially in the case of areas of heavy oiling, direct contact with surface hydrocarbons can result in irritation of the skin and eyes and some individuals may die as a result of exposure.

Oiling, or external contamination of seabirds is particularly problematic and can lead to a loss of insulation, buoyancy, and the ability to fly or swim (as observed for penguins). Seabirds will groom/preen themselves in an attempt to remove any contamination, leading to ingestion and further toxicity effects from any MDO which might have adhered to their feathers. However, MDO has a dispersive nature, and the majority of seabirds are highly mobile so if any hydrocarbon was spilt, a significant/acute impact is unlikely.

In the highly unlikely event that a spill occurs in close proximity to the Victorian or Tasmanian coastline, MDO that reaches the shoreline may impact regionally significant resident breeding populations of seabird and migratory shorebird species (refer to **Table 30**, **Section 4.5.7** for species details).

Nine and 24 seabird species are identified as having breeding and foraging habitat BIAs, respectively, relevant to the Otway Basin 3D MC MSS, based on the results contained within the EPBC Act Protected Matters Report (see **Section 4.5.7**). Two species are identified as having migration/aggregation BIA habitats overlapping with the EMBA.

Although oceanic seabird species can travel long distances to forage in offshore waters, most breeding seabirds tend to forage in nearshore waters near their breeding colony, resulting in intensive feeding by higher seabird densities in these areas during the breeding season and making these areas particularly sensitive in the event of a spill.

For areas identified as a breeding BIA, these are located on shoreline areas, that in the event of an oil spill, may be at risk of exposure to shoreline hydrocarbons. Breeding habitats identified for several seabird species on Philip Island (e.g. little blue penguin, short-tailed shearwater) and the smaller islands off the north west TAS peninsular (short-tailed shearwater) may be susceptible to exposure to low to moderate shoreline hydrocarbon thresholds of exposure. Whilst exposure of nests and eggs to direct hydrocarbon exposure is extremely unlikely given nesting is likely to occur above the high tide range of any potential shoreline accumulation, the likely higher density of birds during nesting, and increased foraging intensity may be at risk to exposure of any shoreline or nearshore water hydrocarbon exposure.

Foraging habitats across many species may be exposed to entrained hydrocarbon exposure. Potential risk of exposure to entrained hydrocarbons in the high threshold is predicted to be of a short duration (several days) under a worst-caste spill scenario, with the bulk of hydrocarbons being lost to evaporation and degradation over time.

Shorebirds foraging for food in intertidal areas or along the high-tide mark may encounter weathered hydrocarbons, subsequently returning to the next and/or ingested. However, by the time this may occur, the hydrocarbons are expected to be heavily weathered and likely to permeate through the sandy areas, limiting the potential accumulation on adult birds. Potential toxicity effects from ingestion of weathered hydrocarbons are not expected due to the properties of MDO, with the volatile aromatics evaporating rapidly after a spill event.

The residual risk to seabirds arising from an accidental release of MDO as a result of a vessel collision/refuelling incident during the Otway Basin 3D MC MSS has been assessed as **Low** (*minor x remote*).

8.3.3.3 Potential Impacts and Risks to Cultural and Heritage Sites

Section 4.6 details the extent of the EMBA that overlaps or is in close proximity with the Native Title Determination Areas, namely areas on the VIC coastline (Gunditjmara and Eastern Maar, Gunditjmara (Part A), Eastern Maar People, Gunai/Kurnai People). There are four protected shipwrecks within the OA, and numerous submerged shipwrecks across the extent of the EMBA overlapping VIC, TAS, NSW and South Australian waters. There are eight Heritage River/Sites identified as overlapping with the EMBA.

Native Title Determination Areas are not shown to extend beyond 200 m into the coastal waters. Shoreline exposure of the coastline intersecting Native Title Determination Areas along the west VIC coastline (Otway to South Australia) from an oil spill may result in exposure to low-moderate thresholds of hydrocarbon exposure, with isolated pockets at Glenelg and Corangamite (west of the Otway) potentially exposed to high thresholds of shoreline hydrocarbons. The probability of this occurring is low (1 – 2% for Corangamite and Glenelg, respectively), estimated to extend over ~1.9 km in the length of the shoreline (RPS, 2023).

Any potential hydrocarbon release is expected to undergo significant physical dispersion and dissolution, prior to any amount being beached. Any potential beached amount is expected to be occur in the mid to low threshold range of hydrocarbon exposure. Natural weathering/attenuation processes are anticipated to adequately mitigate any residual risk of beached oil droplets at these remote locations. Submerged shipwrecks within the OA and on the outer edge of the EMBA are not anticipated to be exposed to surface oil plumes and predicted low concentrations of dispersed/entrained oil to these will not be expected to incur any adverse effects.

The residual risk to cultural/heritage areas arising from an accidental release of MDO as a result of a vessel collision/refuelling incident during the Seismic Survey has been assessed as **Low** (*minor x remote*).

8.3.3.4 Potential Impacts and Risks to Coastal Marine Environment

8.3.3.4.1 Key Ecological Features

The OA overlaps with one KEF, the West Tasmania Canyon KEF. In addition to the West Tasmania Canyon KEF, the EMBA also overlaps with the following additional KEFs:

- Bonney Coast Upwelling;
- Big Horseshoe Canyon;
- Canyons on the Eastern Continental Slope;
- Seamounts South and East of TAS; and
- Upwelling East of Eden.

Across all KEFs, interactions with any spilled hydrocarbons are anticipated to occur to some degree but are anticipated to be restricted to the surface waters, and impacts will decrease markedly with increasing depth. Interactions and any impacts are likely to be restricted to planktonic assemblages in the water column only, and sensitive ecological receptors at depths are highly unlikely to be impacted by any spilled oil. Modelled distribution of entrained oil shows high threshold in the top 10 m of water intersects with the Bonney Coast Upwelling and West Tasmania Canyons KEFs, but this does not extend to deeper waters beyond 20 m. With rapid loss of the bulk of any spilled oil to evaporation and degradation, modelling suggests that for a worst-case spill, between 9 – 11% of the total volume may remain entrained in the water column (RPS, 2023).

8.3.3.4.2 Australian Marine Parks

The OA overlaps two AMPs and the EMBA overlaps with a further eight AMPs. As with KEFs, the greatest risk of exposure to spilled oil for AMPs in the vicinity of the OA is to water column exposure in the top 10 m of water. Deeper waters, and sensitive benthic environments associated with the AMPs are not anticipated to be exposed to thresholds of dissolved or entrained water that pose an ecological risk. Modelled results of worst-case scenarios demonstrate that surface waters across the AMPs are not at risk of exposure to floating surface oil but may be exposed to low to moderate thresholds of dissolved hydrocarbons. The probability of exposure of the Apollo, Zeehan, and Franklin AMPs to moderate (>50 ppb) thresholds of dissolved hydrocarbons is predicted to be low (1 – 6%) (RPS, 2023).

The Apollo, Franklin, and Zeehan AMPs are also predicted to be exposed to high thresholds of entrained hydrocarbons in the event of a worst-case spill from Release Locations 3, 5, and 4, respectively. As with the risk to KEFs, entrained hydrocarbons decrease significantly with depth, and any residual hydrocarbons are highly unlikely to incur any long-term effects to benthic communities in deeper waters across the AMPs.

The Hogan Island and Kent Island Group in the Beagle AMP (in Bass Strait) are at risk of exposure to low threshold shoreline hydrocarbon accumulation from a worst-case oil release. The probability of this occurring is, however, low, and depends on the location of the spill event. With natural weathering and degradation, persistent adverse ecological effects are not expected to occur.

8.3.3.4.3 Other Sensitive Areas

Across the EMBA, other sensitive areas include Ramsar Wetlands, Nationally Important Wetlands, and Threatened Ecological Communities. Assemblages of species commonly associated with Ramsar sites and nationally Important Wetlands are those associated with open-coast-salt-wedge estuaries, as described in **Section 4.4.10.1**.

Location of Ramsar and Nationally Important Wetlands may be exposed to low-moderate thresholds of shoreline oil accumulation in the event of a wors-case oil spill. Western Port, Bellarine Peninsular, and Piccaninnie Ponds Karst Wetlands are potentially susceptible to shoreline accumulation of low-moderate shoreline thresholds.

Exposure to dissolved hydrocarbons is not predicted to occur across Ramsar or Nationally Important Wetlands, but exposure to low thresholds of entrained hydrocarbons may occur at low thresholds (10 ppb) (Corner Inlet, Lavinia, Port Philip Bay and Bellarine Peninsular), and to moderate thresholds (100 ppb) (Glenelg Estuary and Discovery Bay Wetlands, Piccaninnie Ponds Karst Wetlands). The probability of exposure of Ramsar wetland locations to moderate entrained thresholds is very low (1 – 2%) (RPS, 2023).

Giant Kelp forests located in TAS coastal waters (and some remnant patches in VIC and SA) occur subtidally, in waters typically deeper than 8m, and associated with moderate wave exposure (DoCCEEW, 2012). With a dense canopy extending upwards to surface waters, in the event of a worst-case oil spill, the surface extent of any canopy may be exposed to shallow dissolved and entrained hydrocarbon fractions. Results of stochastic modelling indicates TAS nearshore western coastal waters may be exposed to moderate thresholds of entrained hydrocarbons in the surface waters (0-10 m), thus any Gian Kelp canopy extending to shallow surface waters may also be exposed to moderate entrained hydrocarbon thresholds. Deterministic analysis (for Release Location 5, closest to the TAS west coast) predicts 10% of a maximum worst-case spill to remain in the water column after a 50-day modelled simulation. Any residual amount after this 50-day period is expected to exhibit low toxicity thresholds, given the predominant toxicity of MDO is associated with dissolved fractions which rapidly evaporate and attenuate in the receiving environment. Exposure to dissolved MDO is predicted to be in the low threshold range for any nearshore coastal waters along the northwest TAS region. Toxicity at this range, and up to the moderate threshold, is minimal and short lived.

Based on the above and including numerous control measure (**Section 8.3.6**) to be implemented, the residual risk to the coastal marine environment from an accidental release of MDO as a result of a vessel collision/refuelling incident during the Otway Basin 3D MC MSS has been assessed as **Low** (*minor x remote*).

8.3.4 Evaluation of Known and Potential Impacts and Risks to Relevant Persons

Using the information presented in **Section 4** to **Section 5**, the impact and risk assessment has been undertaken for those receptors determined to be relevant to the activity as listed in **Table 124**.

Table 124 Relevant Persons Assessed

Receptor	Section reference
Commercial fisheries	**Section 8.3.4.1**
Commercial shipping	**Section 8.3.4.2**
Tourism and recreation	**Section 8.3.4.3**

Commercial fisheries and coastal shipping operations are considered the most at risk of vessel collisions due to their presence in, or transiting through, the OA. Due to the low potential volumes of an MDO spill that could result from a collision/sinking event, socio-economic impacts on existing interests are likely to be low.

There may be some temporary disruption to fishing activities if a spill occurred and entrained or surface hydrocarbon plume moved through a fishing ground, where it could have the potential to coat the buoys and ropes of fish or rock lobster pots. In the worst-case, larval stages of commercially targeted fish species (e.g. blue warehou, blue grenadier, orange roughy, southern rock lobster, abalone, scallop and squid, see **Section 4.8** for full details) may be affected. Larval stages of other important demersal and pelagic fish species may also be affected, depending on time of the year and location/scale of any potential spill event.

Outcomes of modelled exposure pathways suggest that under a worst-case spill scenario, by the time any MDO made it to shore, for some areas of the VIC and TAS shoreline, it may be at moderate exposure thresholds (10 – 100 g/m^2) that may incur adverse effects. For the VIC coastline from Wilson Promontory, extending west to the South Australian border, low threshold shoreline exposure levels may be indicative of 'perceived' impacts, and there is the potential for some socio-economic impact (visual/aesthetic).

As noted earlier, smaller sections on the west coast of King Island (along with the Corangamite shoreline) may be at risk of exposure to high threshold shoreline accumulation under a worst-case spill scenario. For King Island, this is of high importance for the management of risks to commercial bull kelp harvesting operations (**Section 4.7.3.4.6**).

The most obvious effect from a vessel collision/sinking to existing interests in/around the OA is the potential for casualties and injury. Released debris may float, either at the surface or partially submerged, creating a navigation hazard to other users of the marine environment, while MDO released from the vessel(s) will likely disperse and weather with time, unless making landfall where risks to the public could occur.

8.3.4.1 Potential Impacts and Risks to Commercial Fishing

Following a collision/sinking large debris that settles on the seabed, such as a vessel itself, pose a risk to commercial trawl fisheries. Trawling would not be safe around such debris as trawl gear may become entangled. Zones identified as low to high trawling effort are identified in the northwestern and eastern edge of the OA.

Potential effects of a hydrocarbon spill (such as MDO) on fisheries include effects on fish populations, contamination of equipment (e.g. nets, and boats), displacement from fishing grounds, contamination of catch, loss of revenue from disruption, and negative public perception of fish quality and safety of target species. Given the low volume of MDO that might potentially escape in the event of a collision/sinking, the likely impacts to commercial fisheries would be relatively short-lived, and reasonably localised around the vessel collision/sinking location.

Effects of MDO contamination of oil on submerged kelp forests include tissue damage with bleaching being the most visible indication of plant contact with oil, reduced photosynthesis, and, in the case of heavy oiling events, breakage of kelp fronds (Antrim *et al*., 1995). For commercial marine plant fisheries (formerly kelp fisheries, see **Section 4.7.3.4.6**), any worst case-spill that results in shoreline accumulation of oil along the west coast of King Island, or north-western TAS shoreline, may require the temporary cessation of shoreline harvesting operations until the outcomes of the OPEP (and any response under the OSMP) are known. Commercial kelp harvesting is currently a shoreline/land-based activity. Result of stochastic modelling predict under a worst-case oil spill scenario, shoreline accumulation of oil on the western King Island shoreline has a 3% probability of exceeding the shoreline high threshold, from a worst -case spill from Release location 4, and a 1% probability of exceedance for a worst-case spill from Release location 3 (RPS, 2023). Overall (averaging over the modelled scenarios across an annual period), shoreline oil accumulation across west coast King Island is predicted to affect up to ~47 km of the shoreline at the low exposure threshold, and up to ~2 km of the shoreline at the high exposure threshold.

Any fishing equipment such as nets and lines that contacts a spill may become fouled by hydrocarbons, for example fishing nets towed through spill areas or lifted through surface slicks. However, it is highly unlikely that fishermen will knowingly enter into a spill area, making fouling of equipment unlikely. A more likely effect comes from displacement of fishing vessels from regular fishing grounds, possibly reducing the potential of a vessel to catch their quota or increasing the time and fuel consumption costs by having to travel to other unaffected fishing areas.

Visible hydrocarbons on the sea surface may persist for several days so any potential closures will be temporary (for example 1 – 2 weeks) and will be dependent on the outcome of the spill response process (**Section 10.10**). Economic impacts from loss of revenue and profit due to inability to fish in certain areas following a hydrocarbon spill will initially impact the fishing companies. However, trickle-down effects also occur, with the potential for employees to suffer from loss of wages and job cuts (McCrea-Strub *et al*., 2011), as well as sub-contractors and supply companies becoming effected.

Under the ‘Commercial Fisheries Compensation Protocol for the Otway MC3D Marine Seismic Survey’, commercial fishers may lodge a claim for compensation to be paid as a result of economic losses due to displacement from ‘usual fishing grounds’ as a result of avoiding contaminated waters following a fuel oil spill. Further details on the commercial fisheries protocol are provided in **Section 7.2.3.1.**

The residual risk to commercial fisheries arising from an accidental release of MDO as a result of a vessel collision/refuelling incident during the Otway Basin 3D MC MSS has been assessed as **Low** (*Minor x Remote*).

8.3.4.2 Potential Impacts and Risks to Commercial Shipping

With a major port at Portland on the VIC coastline, heavy vessel traffic in the northwestern extent of the OA, and inshore to the coast is expected, due to vessels heading towards Portland and the major adjoining ports in Port Philip Bay and Port of Devonport (TAS) (refer to **Section 4.7.4**). Traffic within the majority of the OA itself is relatively low (in comparison to the northern extent).

In the event of a vessel collision and significant marine diesel spill, the AMSA JRCC may issue a warning to shipping traffic in the area to avoid the incident location. Exclusion zones surrounding a spill will reduce access for shipping vessels for the duration of the response undertaken for spill clean-up (if applicable); vessels may have to take detours leading to potential delays and increased costs.

Debris left floating in the ocean following a vessel collision/sinking provides a hazard to marine shipping traffic and may force vessels to reduce speed in the known area of a debris field, or alter courses to avoid the area, reducing efficiency. This would be advised via safety communications and Notices to Mariners to alter regular routes to avoid movement through contaminated areas and areas involving clean-up activities. This impact would apply to both offshore and coastal routes.

Due to advance communications and vessel's ability to alter course to avoid floating debris and/or hydrocarbon spills, the environmental risk and subsequent effect of a vessel collision/sinking on commercial shipping would be **Low** (*minor x remote*).

8.3.4.3 Potential Impacts and Risks to Tourism and Recreation

As described in **Section 4.7.2**, the SEMR offers a wide and diverse range of opportunities for marine based tourism and recreational activities, including snorkelling, scuba diving, surfing, kayaking, whale and wildlife watching, sailing and charter boat cruises. Popular tourist destinations include Phillip Island and the Great Ocean Road (VIC), Robe and Beachport (South Australia) and Strahan and the Freycinet Peninsula (TAS) (CoA, 2015).

Tourism and recreational activities in the region occur predominantly in State waters adjacent to population centres/coastal settlements. Charter vessels may occasionally transit through the EMBA, however interactions with the Otway Basin 3D MC MSS are considered unlikely due to the offshore location of the OA. Whale watching activities are largely undertaken from shoreline-based locations, with occasional vessel and aircraft. Recreational diving is largely confined to nearshore water depths of 30 m or shallower, thus out of the depth and vicinity of the OA. Similarly, surfing, recreational boating and fishing are largely confined to the nearshore state waters, and are not likely to overlap with the OA.

Risks of entrained or shoreline hydrocarbons potentially pose the greatest risks to tourism and recreational activities, through the physical presence of the oil in the water column (entrained) and risks of shoreline accumulation. As described in **Section 8.3.2**, in the event of a worst-case oil spill, the shoreline across the VIC and TAS coastlines are susceptible to low-moderate thresholds of hydrocarbon exposure, and in isolated pockets to high-thresholds of exposure (at Corangamite and King Island). Exposure to high thresholds of entrained hydrocarbons are predicted to occur in nearshore waters of King Island and Glenelg, with the wider extent of the EMBA subject to a range of moderate to low exposure thresholds.

Debris released from a collision/sinking may pose a temporary and localised navigational risk to recreational and tourism vessels plying the coastal waters and drifting or washed-up debris could have negative effects on the aesthetic qualities of the area for tourists. Effects of a hydrocarbon spill on tourism and recreational activities include lost abilities to carry out activities due to loss of habitats, displacement of tourism/recreational vessels from areas (e.g. within oil slicks and during clean-up activities), displacement of marine organisms (which may have attracted tourists) by presence of slicks, and loss of revenue from changes in public perception including reduced aesthetic qualities of coastal environments where hydrocarbons land or persist. As a result of these potential impacts to tourism and recreational activities if a spill occurred, the impacts are considered to be **Low** (*minor x remote*).

8.3.5 Decision Context

The decision context for vessel collision, sinking and bunkering and any associated hydrocarbon spill has been assessed as Type A given the predicted impacts and risks are well understood and uncertainty is minimal.

8.3.6 Identification of Control Measures, Residual Risk Assessment and Demonstration of ALARP

The potential control measures implemented during the Otway Basin 3D MC MSS to manage any potential impacts and risks from vessel collision, sinking, bunkering incidents and associated hydrocarbon spill to **ALARP** have been included in **Table 126**. TGS has considered a number of control measures to determine the benefits of their implementation towards risk reduction (**Table 126**), based on a Hierarchy of Controls methodology (**Table 125**). These control measures have been assessed to consider the environmental benefits gained through implementing the controls and characterised as effective and practicable to implement.

Table 125 Hierarchy of Control Measures for Vessel Collision, Sinking, Bunkering and Associated Hydrocarbon Spill

Eliminate	The use of vessels cannot be eliminated as a Seismic Vessel must be used to undertake the required data collection. The OA is also an open ocean area where other vessels (fishing, shipping, cargo, recreational) are not restricted from entering and may pass through any part of the area (within reason) at any time thus other vessels cannot be eliminated either. A Support Vessel is also needed for several reasons and cannot be removed from the operations. Refuelling at sea cannot been eliminated from the Otway Basin 3D MC MSS, thus this source of risk cannot be eliminated. Refuelling at port would incur more frequent vessel movement and increase the risk of vessel collision. The consequence of vessel collision and associated hydrocarbon spill are higher than those associated with potential hydrocarbon loss associated with refuelling at sea.
Substitute	There are no suitable substitutes for use of a Seismic Vessel to undertake the survey in the required location.
Reduce	TGS aims to reduce the amount of time the vessels are in the OA by working 24/7 whenever possible. Reducing the number of vessels by removing the presence of a Support Vessel could reduce the risk of a collision/sinking. But at the same time this reduction could increase the risk of a collision between other vessels and the Seismic Vessel and/or its towed equipment. Thus, a reduction in the number of vessels isn't a practicably feasible option. Refuelling at sea will occur approximately every 2 - 6 weeks, undertaken within the OA, and to be kept to a minimum to reduce vessel traffic.
Mitigate	Control measures have been assessed within **Table 126** in order to mitigate the impacts from a possible vessel collision/sinking to **ALARP** levels. Those which are appropriate and are not impracticable or unfeasible due to disproportionately large costs will be implemented during the Otway Basin 3D MC MSS.

Table 126 Assessment of Control Measures for Vessel Collision, Sinking, and Bunkering and Associated Hydrocarbon Spills

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Legislative Requirements:			
The Otway Basin 3D MC MSS will be undertaken in accordance with the approved EP.	P = Yes E = Effective	All vessels undertaking an offshore activity in waters between 3 and 200 NM must undertake that activity in line with an approved EP. The approved EP outlines the measures that will be taken to ensure that environmental effects from the activity will be reduced to **ALARP** and **Acceptable Levels**, including the management of vessel collision, sinking and bunkering and associated hydrocarbon spills.	Yes
All survey vessels will adhere to the requirements of the national and international legislation, including the International Regulations for Preventing Collisions at Sea 1972 (COLREGS) and Chapter 5 of Safety of Life at Sea (SOLAS) as implemented in Commonwealth Waters through the Navigation Act 2012 and associated Marine Orders 21, 30, 91 and the STCW Convention. The requirements give effect, but are not limited to, the following: • Appropriate lighting, navigation and communication to inform other marine users; and • Use of radar and 24/7 watch.	P = Yes E = Effective	At all times during the survey the crew of the survey vessels will comply with COLREGS, including maintaining a visual watch and undertaking a full radar scanning watch for the presence of any other vessels in close proximity or any vessel on a course heading towards them or the other vessel involved in the Otway Basin 3D MC MSS. Early detection of approaching vessels will allow the survey vessels to attempt to communicate with approaching vessels to avoid chances of collision. The slow speed of the vessels during the operational phase of the survey (4 – 5 knots) will then also allow the vessels plenty of time to attempt communication following early detection and if required make appropriate evasive manoeuvres. In addition to the above, having navigational lighting and day-shapes compliant with COLREGS for safe passage at sea and specific to each vessel and its activities will provide further means in reducing the chance of vessel collisions. In accordance with Marine Order 91, if a MDO spill does occur following a vessel collision/sinking TGS will implement the response strategy in accordance with the SOPEP, and also in line with relevant legislation and industry standards. TGS will also undertake all required notification and reporting during planning stages of mobilisation phase of survey. In the event of a vessel collision/sinking and there is a resultant MDO release, notification will be provided to AMSA and regulatory agencies in accordance with the Implementation Strategy – Reporting **Section 10.6**	Yes
Vessels over 400 gross registered tonnage hold and approved and tested SOPEP, with crew trained in its implementation.	P = Yes E = Effective	This control measure meets the requirements of Annex I of MARPOL which requires vessels over a certain size to have a SOPEP. Having crew trained in the implementation of the SOPEP will reduce the likelihood of a spill response option being required, by reducing the likelihood of a spill occurring in the first place. The Vessel Master is responsible for activating and implementing the vessel SOPEP. Prior to the commencement of survey operations, the SOPEP will be tested including testing of communications and a vessel-based drill in hydrocarbon spill response. It is a legislative requirement for vessels to comply with MARPOL.	Yes
In the event of a spill to the marine environment, the OPEP will be implemented.	P = Yes E = Effective	In accordance with the requirements of the Environment Regulations, an OPEP accompanies this EP, which details the spill preparedness and response arrangements that will be implemented in the event of a spill. The OPEP includes arrangements for notifying AMSA and engaging the National Plan resources.	Yes

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Good Industry Practice:			
Vessel will only utilise MDO. Vessel fuel to be stored in compartmentalised and/or multiple separate onboard fuel tanks.	P = Yes E = Not Effective	Utilising a certain type of fuel is not effective in reducing the risks of a vessel collision and hydrocarbon spill, but it is important for considering the types of responses required for clean-up. Utilising MDO would have less impacts on the marine environment should a spill occur compared to other heavier oils and the same level of response would not be required for the clean-up. Finally, this fuel type is consistent with that which for which the impacts have been modelled. Fuel systems onboard the survey vessels (carrying MDO) will consist of multiple smaller tanks throughout the vessel or larger tanks built of multiple separate compartments. This will reduce the potential volumes of MDO that could be released to the environment in the event of a tank being ruptured during a collision/sinking event. Good industry practice, environmental benefit outweighs additional cost.	Yes
Refuelling will occur away from the Zeehan AMP and the Nelson AMP.	P = Yes E = Effective	Refuelling will not occur within 5 km of the Zeehan Marine Park or Nelson Marine Park, as shown in **Figure 92**. These separation distances will minimise the risk of adverse effects occurring on the values present in these higher risk areas. Environmental benefit outweighs additional cost.	Yes
Appropriate use of radio communication at sea.	P = Yes E = Effective	Survey vessels will keep open radio communications between each other as well as scanning local working channels and the emergency channel (VHF 16) for contact with other vessels that may be operating in the vicinity, and therefore reduce the potential for collision. Good industry practice, environmental and safety benefit outweighs additional cost.	Yes
Utilising accurate weather forecasting information for planning operations.	P = Yes E = Effective	TGS will subscribe to a weather monitoring service that will provide updated forecasts (including wind, waves/seas and currents) four times daily allowing vessel masters to best plan the vessels movements and operations to occur when and where in the OA the weather is safest/most-suitable. Good industry practice, environmental and safety benefit outweighs additional cost.	Yes
Contract in place with appropriate service provider to initiate real-time modelling in case of a spill.	P = Yes E = Effective	Undertaking real-time modelling will provide assurances that response options can be tailored to the specific spill situation. The modelling will be based continuous weather monitoring which will be utilised in conjunction with hindcast data to predict the potential beaching locations (if any exist).	Yes
In case of a spill <10m^3, TGS will implement relevant Type I Operational Monitoring.	P = Yes E = Effective	Type I Operational Monitoring (such as using the Support Vessel to monitor the spill) will be undertaken in the unlikely event of a hydrocarbon spill to provide up-to-date information on the fate of hydrocarbon in the water. This monitoring will allow appropriate response options to be established with the Controlling Authority. Good industry practice, safety benefit outweighs additional cost.	Yes
Type II Scientific Monitoring undertaken (informed by updated NEBA/Spill Impact Mitigation Assessment (**SIMA**)) in case of spill if real-time modelling shows the spill will impact land, in consultation with the CA.	P = Yes E = Effective	Depending on the fate of any hydrocarbon spill, based on the real-time modelling and operational monitoring described above, Scientific Monitoring may be required (if directed by the Controlling Authority) to monitor the impacts from a spill occurrence. Good industry practice, environmental benefit outweighs additional cost.	Yes
Hydrocarbon spill response training and competencies will be maintained throughout the Otway Basin 3D MC MSS to avoid unplanned environmental impacts due to human error.	P = Yes E = Effective	Ensuring all staff members have appropriate training is vital in responding to a hydrocarbon spill. Drills will also be undertaken to ensure all staff are competent in responding to spills under the vessel specific SOPEP; these drills will be conducted at regular intervals to ensure the competencies are maintained throughout the operation. Good industry practice, environmental and safety benefit outweighs additional cost.	Yes
AIS transponders fitted to survey vessels and tail buoys.	P = Yes E = Effective	AIS transponders will transmit key information to all vessels able to receive AIS data and will include details such as vessel GPS position, identity, type, speed, course and caution notes). The AIS system will also receive AIS information from other vessels in the area. Good industry practice, environmental and safety benefit outweighs additional cost.	Yes

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
All crew will participate in the vessel and environmental induction prior to the commencement of operations.	P = Yes E = Effective	It is a standard industry practice to hold inductions for all onboard the vessels, with participation in induction meetings compulsory. During inductions, crew will be made aware of their responsibilities with regard to effects of discharges to the marine environment and their roles with regard to clean-up of any accidental discharges. Good industry practice, environmental and safety benefit outweighs additional cost.	Yes
Spill response equipment will be available and maintained onboard each vessel and located in close proximity to hydrocarbon areas and crew onboard will be trained in how to respond to any incident utilising the response equipment available.	P = Yes E = Effective	The availability of spill response equipment in close proximity to any hydrocarbon areas allows a quick response to any hydrocarbon spills into the marine environment. Vessel master will authorise actions in accordance with the vessel-specific SOPEP and the survey specific OPEP to limit the escape of hydrocarbons. Good industry practice, environmental and safety benefit outweighs additional cost.	Yes
Undertake hydrocarbon spill modelling prior to EP submission.	P = Yes E = Effective	A hydrocarbon spill modelling prior to the submission of this EP has been undertaken and was considered being useful to map the potential risks of vessel collision and hydrocarbon spills. As the OA covers a very wide area it is difficult to determine the ideal location to base the modelling on, thereby the spill modelling was undertaken at five different locations (see method and results in **Section 8.3.2**). As outlined in the control measures to be implemented above, TGS will also implement real-time modelling in the event of a spill which will provide more detailed and realistic areas of potential beaching along the coastline to assist in responding to a spill occurrence. Good industry practice, environmental benefit outweighs additional cost.	Yes
A communications protocol will be in place between the survey vessels and other relevant persons (e.g. commercial fishers known to utilise the OA, oil and gas operators), to actively manage concurrent activities.	P = Yes E =Effective	A communications protocol will be in place which details the methods used to contact third-party vessels prior to commencement of the Otway Basin 3D MC MSS, throughout the survey duration, and following completion of the survey, and those identified only once at sea, to actively manage concurrent activities. Communication with relevant persons allows those potentially affected by the Otway Basin 3D MC MSS to plan activities in a manner that reduces the risk of interactions with the survey vessels and towed equipment (e.g. commercial fishers can avoid deploying gear in the path of the Seismic Vessel). TGS will provide a daily 'look-ahead' plan, which details the proposed operations for the next 48-hour period. Information regarding proposed operations will include, as a minimum, the current positions of the survey vessels and the proposed timing and location of operations for the following 48 hour period. These will be provided daily to those relevant persons who register for the service. As part of this communication, TGS will request information from commercial fisheries on upcoming fishing activities for the next 24 – 48 hours. This will allow the Seismic Vessel to consider alternative lines, where practicable. The Seismic Vessel will change sail lines to accommodate commercial fishers' requests if it is feasible to do so, providing there is open and advanced communication from the commercial fishing operator of their intention to fish at a specified location, no other environmental performance commitments in this EP conflict with a change in sail lines, and providing TGS is afforded a reasonable opportunity to complete the Otway Basin 3D MC MSS in a timely and efficient manner. This control measure has been proposed in response to consultation with relevant persons. Good industry practice, safety benefit outweighs additional cost.	Yes
Notification to the AHO for the publication of a Notice to Mariners of survey presence and towed array, no less than four weeks before operations commence.	P = Yes E = Effective	Under the Navigation Act 2012, AHO can publish and distribute a Notice to Mariners. This Notice outlines potential hazards and restrictions to relevant persons. AHO will be contacted four weeks prior to the commencement of the survey for the publication of related Notices to Mariners. Good industry practice, safety and socio-economic benefit outweighs additional cost.	Yes
Notification to the JRCC for the promulgation of navigational warnings (i.e AUSCOAST warnings)	P = Yes E = Effective	The JRCC will be contacted 24 – 48 hours before operations commence for issuing of radio-navigation warnings. This will ensure that commercial fishers are aware of the Otway Basin 3D MC MSS. Implementation will reduce the likelihood of interactions with commercial fishing vessels. Good industry practice, safety benefit outweighs additional cost.	Yes

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Notification to the DNP in the event of an oil spill.	P = Yes E = Effective	The DNP should be made aware of unplanned events such as an oil spill which occurs within an AMP, or is likely to affect any AMPs, as soon as possible. Parks Australia plays a role in the National Plan for Maritime Environmental Emergencies. The DNP should be notified through notification to the Marine Park Compliance Duty Officer (0419 293 465). Notification should include: titleholder details, time and location of the incident, proposed response arrangements and locations as per the OPEP, and contact details for the response.	Yes
At least one Support Vessel will accompany the Seismic Vessel when in operation and when safe to do so (e.g. outside of inclement weather periods), to manage interactions with other marine users.	P = Yes E = Effective	Support vessels (Support Vessel and Chase Vessel) will be present around the Seismic Vessel to intercept other vessels in the area that are at risk of interacting with the Seismic Vessel and/or equipment. This is a health and safety requirement and is standard practice for all MSSs. Implementation will reduce the likelihood of interactions, reducing the potential for a vessel collision. Good industry practice, environmental and safety benefit outweighs additional cost.	Yes
Seismic survey vessel contractor procedures include requirements to be implemented during refuelling operations, including: • A completed Permit to Work; • A Job Safety Analysis (**JSA**) implemented for bunkering operations; • Visual monitoring of gauges, hoses, fittings; • Sea surface bunkering; • Hose checks prior to commencement; • All crew are spill response trained; and • Spill response equipment is nearby, easily accessible and fully stocked	P = Y E = Effective	Each survey vessel will have refuelling and bunkering procedures outlining the steps to be taken during refuelling operations to ensure this is carried out in a safe manner and without incidents.	Yes
Dry-break couplings will be installed on refuelling hoses.	P = Y E = Effective	Dry-break couplings will be used to reduce the risk of a refuelling incident from occurring. Good industry practice. Environmental benefit outweighs additional cost.	Yes
At sea refuelling operations will only take place during daylight hours and within strict weather limit guidelines.	P = Yes E = Effective	Refuelling will only be undertaken during daylight hours and appropriate weather/sea conditions. Implementation of this control will reduce the risk of a refuelling incident from occurring. By limiting refuelling to daylight hours also reduces the likelihood of a spill entering the marine environment. Environmental benefit outweighs additional cost.	Yes
Alternatives/Substitutes Controls Considered:			
Eliminate vessels.	P = No E = Very Effective	There are no practicable methods for undertaking the Otway Basin 3D MC MSS without the use of vessels.	No
Eliminate presence of other hydrocarbon fluids onboard vessels (e.g. lubricants, hydraulic fluids).	P = No E = Effective	Lubricating and hydraulic fluids are required for the normal operation and maintenance of the vessels and equipment and as such cannot be completely eliminated. Storage in suitably bunded areas as detailed above will reduce risk associated with these fluids. Lubricating oils and hydraulic fluids are typically stored in 50 – 200 L steel drums either in a designated storage room, or a bunded area on deck. Therefore, any potential spills of these substances on deck are likely to be <200 L in a contained area. Hydrocarbons which occur in greater (>200 L) quantities on the vessels, for example waste engine oil, hydraulic fluid and main engine lubricating oils, are generally stored in designated storage tanks below deck and therefore are unlikely to be a direct hazard for deck spills (unless smaller quantities have been transported to the deck to be used for deck activities). It is possible that spills or leaks from hydraulic hoses on hydraulically operated equipment such as cranes and winches may occur, but if so, the fluid is likely to be contained within a bund or drip tray, and the volume of fluid loss will be low (<1 L). It is therefore highly unlikely that a non-contained spill of hydrocarbon fluids will occur onboard vessels; however, should such fluids enter the marine environment, their impact is likely to be low-minimal as the small volumes will quickly evaporate, disperse and weather.	No

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Substitute MDO for an alternative fuel or wind-powered vessels.	P = No E = Not Effective	MDO is already a vast improvement over HFO, and lighter alternative fuels or wind power are not feasible to use in the vessels that will be utilised for the survey as they have not been commercially proven for use in large vessels. It is expected that the high energy marine environment in which the OA is located will aid in the rapid dispersion (in the direction of the prevailing wind and current) and evaporation of MDO should it enter the marine environment. Warmer water temperatures during summer months will further accelerate this process.	No
No refuelling will occur at sea.	P = No E = No	Refuelling operations are one of the most likely causes of a hydrocarbon spill occurring during marine operations. However, given the offshore location of the OA this activity cannot be removed from the operation of the Otway Basin 3D MC MSS. It is not considered a practical option and given the probable increase in vessel activity associated with bunkering, it is not considered effective at significantly reducing risk. The removal of this activity would reduce the potential risk of a hydrocarbon spill occurring in the first place, and the potential impacts of a spill on the environment. Removing the refuelling operations at sea from the Otway Basin 3D MC MSS will potentially increase the risks to the health and safety of employees.	No
Additional Control Measures Considered:			
Use a Seismic Vessel with smaller fuel and oil tank sizes.	P = No E = Effective	This would mean more frequent trips to port for refuelling which would increase costs and the duration of the survey, as well as result in greater risks. Furthermore, implementing this control measure would likely lead to a delay in the timing of data acquisition due to the time needed to contract an appropriate Seismic Vessel. Data delivery to clients would consequently be delayed and requirements not met.	No
The Otway Basin 3D MC MSS will be restricted to daylight hours.	P = No E = Effective	The cost of the survey would increase substantially as the survey duration would double. Health and safety risks and potential impacts to marine life (e.g. cetaceans) would also increase due to the longer survey duration.	No
Reduce size of the OA to decrease chance of spills reaching emergent lands.	P = No E = Effective	The size of the OA has already been reduced substantially. Further reductions would result in TGS being unable to fulfil primary objectives of the survey and data requirements. The likelihood of vessel collision or sinking and an associated hydrocarbon spill is extremely unlikely and is no greater than that for other vessels that may enter the OA and surrounding waters.	No
Dedicated spill response vessel and resources on standby.	P = No E = Effective	The option of having a dedicated spill response vessel on standby for the Otway Basin 3D MC MSS was discounted on the basis that the cost would be grossly disproportionate to any reduction in risk which is already determined to be low, particularly as the expected behaviour of an MDO spill would limit the effectiveness of on-water response options. Additional vessels could also increase the risk of interference and potential for collisions.	No
Residual Risk of Impact (Receptor)	**Consequence**	**Likelihood**	**Risk Ranking**
Marine environment quality	Minor	Remote	Low
Benthic invertebrates	Minor	Remote	Low
Zooplankton, fish eggs and larvae	Minor	Remote	Low
Bony fish and elasmobranchs	Minor	Remote	Low
Marine reptiles	Minor	Remote	Low
Cetaceans	Minor	Remote	Low
Seabirds and migratory shorebirds	Minor	Remote	Low
Cultural and heritage sites	Minor	Remote	Low
Marine Protected Areas	Minor	Remote	Low
Commercial fisheries	Minor	Remote	Low

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Commercial shipping	Minor	Remote	Low
Tourism and recreation	Minor	Remote	Low
ALARP Statement			
The decision context has been assessed as Type A and the overall residual risk has been determined to be **Low**. TGS considers the adopted control measures are sufficient to minimise the risk of impacts from a vessel collision, sinking, and bunkering incidents and associated hydrocarbon spill are appropriate to the nature and scale of the predicted environmental impacts. The proposed control measures have been developed in accordance with Good Industry Practice and legislative requirements, and taking into account the specific environmental, social, economic and cultural characteristics of the OA and predicted impacts to other marine users. Additional control measures were considered as part of the assessment process; however, it was considered that they did not provide any further environmental benefit or were not reasonably practicable to implement. Therefore, the predicted impacts to receptors from a vessel collision and associated hydrocarbon spill are reduced to **ALARP**.			

8.3.7 Impact and Risk Acceptability

Table 127 Demonstration of General Risk Acceptability for Vessel Collision, Sinking, and Bunkering and Associated Hydrocarbon Spill

Criteria for Acceptance	Acceptability Summary
Residual Risk Ranking	The residual risk has been determined to be Low.
Ecologically Sustainable Development	The management of the impacts associated with vessel collision, sinking and bunkering incident and associated impacts (e.g. hydrocarbon spill) can be carried out in compliance with principles of ESD as defined within the EPBC Act. The assessment has not identified any adverse impacts to the principles of ESD, with no threats of serious or irreversible damage, no impacts to biological diversity and ecological integrity, no degradation of inter-generational equity, or negative effects on the social and economic integrity in the short or long-term.
TGS Internal Context	The proposed management of the risks associated with the establishment of IMS is consistent with TGSs QHSE Policy commitments of: • Protecting the environment; and • Conducting operations in an environmentally sustainable and responsible manner.
Existing Environmental Context	In the remote likelihood of a collision/sinking which results in a hydrocarbon and/or debris release, impacts to the marine environment are not expected to be long-term, given the properties of MDO in the ocean, with full recovery in time. Consideration has been given to the potential impacts on the environmental sensitivities within the OA. Of relevance to the OA, is the potential risk of impact to protected species such as marine mammals (including the PBW and SRW), threatened/vulnerable shark and pelagic fish species, marine turtles and seabirds. Following the implementation of control measures the potential risk of any impacts occurring to protected species are considered to be Low. In the unlikely event that a spill occurs, toxicity will be highest in areas close to the spill source. However, MDO is expected to rapidly evaporate and disperse/partition the offshore environment, reducing the acute toxicity of the spill. Whilst some of the potential impacts to sensitive receptors identified were substantial, including localised mortality (e.g. zooplankton), toxic effects (e.g. pelagic fish) and/or, in the case of oil beaching, disruption or damage to important habitat (e.g. seabird nesting habitat), the effects are expected to be localised and short term. Therefore, the threat to protected ecological populations was considered to be Low. Due to the low risk of potential impacts to benthic habitats and communities which contribute to the value of protected areas such as the Zeehan AMP and Nelson AMP, the West Tasmania Canyon KEF, impacts to these sensitivities are not expected. The release of hydrocarbons has the potential to impact the coastal environment and, by extension, sites of cultural heritage value through beaching. The worst-case outcome from the simulations resulted in 11% of the spilled volume beaching on the VIC western coastline, across a stretch of coastline determined to have native title. Results of the modelling indicate that rapid dispersion and evaporation of MDO will significantly reduce the volume reaching shoreline locations where this material will be broken down through natural weathering and biodegradation. Based on this assessment and the implementation of proposed control measures, the risks to the coastal marine environment and sites of cultural heritage value are considered Low. Debris released from a collision/sinking may pose a temporary and localised navigational risk to commercial shipping and tourism operations, as well as causing temporary impacts to visual amenity which preclude typical tourism activities. Additionally, impacts to the profitability of fishing activities following a hydrocarbon spill are expected to impact fishers and their associated operations initially. Following the implementation of the proposed control measures these potential impacts to shipping, tourism, recreational and commercial fishing activities if a spill occurred, the impacts are considered to be Low. The proposed control measures provide appropriate protection to the marine environment and from the risk of vessel collision/sinking and associated effects (debris and hydrocarbon release), and further/alternative control measures would give very little or no further protection from vessel collision/sinking while greatly increasing time and cost of the survey and also increase the potential conflict and displacement with the fishing industry.

Criteria for Acceptance	Acceptability Summary
Existing Environmental Context - Management Plans, Species Recovery Plans and Conservation Advice	The residual risk of a hydrocarbon spill response has been determined to be Low and will not have a significant impact on a matter of national environmental significance in accordance with EPBC Act Policy Statement 1.1. The OA overlaps with two AMP boundaries (the Zeehan AMP and Nelson AMP), and the EMBA overlaps with a further eight AMPs (the Apollo AMP, Franklin AMP, Boags AMP, Murray AMP, Huon AMP, Tasman Fracture AMP, Beagle AMP, and East Gippsland AMP). Oil pollution response, environmental monitoring and remediation activities can be undertaken with IUCN Category VI zones (multiple use zones that include all AMPs in the OA and overlapping with the EMBA) when undertaken in accordance with a NOPSEMA approved EP that has met all required environmental management arrangements for the activity covered in the class approval. However, any oil pollution incident that may affect other IUCN category zones requires prompt consultation with the Director of National Parks. Any spill occurring within, or likely to impact, any AMP should be notified to the Director of National Parks as soon as possible, by contacting the Marine Park Compliance Duty Officer (0419 293 465). Notifications must include time and location of the incident, response arrangements as per the OPEP and contact details for titleholder and response coordinators.
Social Acceptance – Relevant Persons Expectations	During consultation with relevant persons no concerns about the impacts from responding to a hydrocarbon spill were raised and as such no additional control/mitigation measures were expected or put in place. However, the DNP noted that they are to be made aware of oil/gas pollution incidences which occur within a marine park, or are likely to impact on a marine park, as soon as possible. To ensure this expectation is met, a corresponding control measure is proposed to be implemented, as outlined in **Table 128**. Concerns were raised by relevant persons around the potential for an MDO spill to detrimentally affect stocks of commercially harvested kelp, accumulate on beaches (and affect a pristine image), and have long-term and/or permanent impacts. With the strict control measures in place to ensure there are no MDO spills into the marine environment, the risk of environmental impacts relating to MDO spill from survey vessels are considered to be at a socially **Acceptable Level.** As such, the environmental impacts relating to responding to a hydrocarbon spill were considered to be at a socially **Acceptable Level**.
External Context – Commonwealth and State Legislative Criteria	The proposed control measures for vessel collision/sinking/refuelling incidents during the Otway Basin 3D MC MSS are consistent with the following relevant legislation: • The Navigation Act 2012 - requires approved navigation systems for maritime safety, navigation efficiency and management of marine pollution; • The PSPPS Act; • The Environment Regulations; and • Control measures relating to hydrocarbon spills to the ocean are consistent with MARPOL (Annex 1 Regulations for Prevention of Pollution by Oil) and Marine Order 21, 30 and 91, including having an approved and tested SOPEP for all vessels involved in the survey.
Industry Best Practice	The proposed control measures to decrease vessel collision, sinking and bunkering incidents follow industry best practice and best practice guidelines, including: • The IAGC Environmental Manual for Worldwide Geophysical Operations which contains recommendations for SOPEPs, the mitigation of spills and leaks, and incident reporting; and • APPEA Code of Environmental Practice: offshore geophysical surveys are recommended to have environmental objectives to reduce impacts from spills and disturbance to seabed (e.g. in event of sinking), including having evidence of appropriate management procedures and emergency response plans being in place.
ALARP	Total elimination of all risks associated with potential vessel collision, sinking and bunkering incidents cannot be achieved as there are no practicable alternatives to using vessels to undertake the survey safely and effectively. Following the implementation of the control measures detailed in this assessment, the impacts/risks to the marine environment and associated receptors from vessel collision/sinking could have minor consequences. In the remote likelihood of a vessel collision, sinking and bunkering incident which results in a hydrocarbon and/or debris release, impacts to the marine environment are not expected to be long-term, given the properties of MDO in the ocean, with full recovery in time. The risks of a vessel collision occurring are reduced in a number of ways, including the adherence to legislative requirements and industry best practice, along with operating conditions (such as vessel operating at slow speeds). Therefore, the risks associated with a vessel collision and any associated hydrocarbon spill is considered to be **ALARP**. Should an unlikely vessel collision occur, which results in a hydrocarbon spill, TGS has put in place numerous measures to ensure monitoring of the situation is maintained to allow appropriate remediation. Therefore, the residual risk of a vessel collision occurring, with the associated controls in place, is considered to be at an **Acceptable Level**.

Acceptability Statement
Impacts and risks classified as Type A are considered acceptable if the requirements in **Table 51** can be demonstrated and it can be determined that the predicted levels of impact and/or residual risk are at or below pre-defined acceptable levels for that impact or risk, including those described in **Table 52**. Based on the above evaluation, the potential impacts from potential vessel collision, sinking and bunkering incidents meets the requirements of the risk acceptability criteria. The control measures that will be implemented throughout the Otway Basin 3D MC MSS have been developed in accordance with these criteria and are considered appropriate to manage the impacts of a hydrocarbon spill response on all receptors to an **Acceptable Level**.

8.3.8 Environmental Performance

Table 128 Environmental Performance Outcomes, Standards and Measurement Criteria for Vessel Collision, Sinking, Bunkering and Associated Hydrocarbon Spill

Number	Environmental Performance Outcome	Environmental Performance Standard(s)
EPO 26	No collision with other marine users	**EPS 244** - **EPS 253**, **EPS 263** - **EPS 264**, **EPS 269** - **EPS 270**, **EPS 273** - **EPS 281**
EPO 27	No release of hydrocarbons into the marine environment	**EPS 244** - **EPS 245**, **EPS 254** - **EPS 255**, **EPS 265** - **EPS 268**, **EPS 270** - **EPS 272**, **EPS 282** - **EPS 285**

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
The Otway Basin 3D MC MSS will be undertaken in accordance with the approved EP.	**EPS 244**: The Otway Basin 3D MC MSS may only commence following acceptance of the EP by NOPSEMA.	Pre-mobilisation audit and inspection are completed prior to operations and confirm an accepted EP has been obtained. Audit records verify compliance with the requirements of the EP.	TGS VOM EA
	EPS 245: The Otway Basin 3D MC MSS will be undertaken in accordance with the accepted EP.	Bridge logs verify compliance with the requirements of the EP. Audit records verify compliance with the requirements of the EP.	TGS VOM VOC EA Vessel Master SEA
All survey vessels will adhere to the requirements of the national and international legislation, including the International Regulations for Preventing Collisions at Sea 1972 (COLREGS) and Chapter 5 of SOLAS as implemented in Commonwealth Waters through the *Navigation Act 2012* and associated Marine Orders 21, 28, 30, 58 and the STCW Convention. The requirements give effect, but are not limited to, the following: • Appropriate use of lighting, navigation and radio communication at sea; and • 24-hour bridge and radar watch by qualified watch-keepers to monitor for other marine users.	**EPS 246**: At all times the Vessel Masters comply with the requirements of national and international legislation and conventions including (but not limited to) the Navigation Act 2012 (specifically Marine Order Part 21, 27, 30, 58) COLREGS, Chapter IV (Radio communications) and Chapter V (Safety of Navigation) of SOLAS (International Convention on the Safety of Life at Sea 1974) and the STCW Convention.	Vessel Crew Training and Competency records demonstrate that all relevant marine crew are competent to STCW95/Elements of Shipboard Safety Standards. Pre-mobilisation audit and inspection are completed prior to operations and identify no records of survey vessels failing to comply with appropriate navigation and communication requirements under the Navigation Act 2012, associated Orders or conventions. Bridge logs verify this during the Otway Basin 3D MC MSS.	Vessel Master Party Chief SEA
	EPS 247: Lighting and communications equipment onboard all vessels to adhere with COLREGS, the *Navigation Act 2012* and with AMSA Marine Orders Part 30: Prevention of collisions, Part 21: Safety and emergency arrangements and Part 27 (safety of navigation and radio equipment).	Pre-mobilisation audit and inspection are completed prior to operations and identify no records of survey vessels failing to comply. Bridge logs verify this during the Otway Basin 3D MC MSS.	Vessel Master Party Chief
	EPS 248: The survey vessels will have the appropriate communication equipment onboard and will be contactable and also able to communicate with other vessels by radio at all times (i.e. VHF and SSB radio).	Bridge logs confirm VHF and SSB radio communications are always available.	Vessel Master Party Chief

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
	EPS 249: The Seismic Vessel displays day shapes and lights (during hours of darkness/poor visibility) to indicate that the vessel is towing equipment resulting in the Seismic Vessel being restricted in its ability to manoeuvre.	Pre-mobilisation audit and inspection are completed prior to operations and confirm that the relevant equipment is onboard, tested and operational. Bridge logs verify this during the Otway Basin 3D MC MSS.	Vessel Master Party Chief
	EPS 250: The Seismic Vessel is equipped with Radar and AIS systems which will be operating and monitored at all times for both transmitting and receiving vessel positions in the surrounding vicinity.	Pre-mobilisation audit and inspection are completed prior to vessel leaving port and confirm Radar and AIS are present and operational. Bridge logs confirm Radar and AIS are used.	Vessel Master. Party Chief SEA CSR
	EPS 251: The Seismic Vessel will have ARPA onboard for the detection of other vessels. The ARPA system can track other vessels speed and heading and can monitor for the potential of any collisions so the vessels can be contacted prior to any situation occurring.	Pre-mobilisation audit and inspection are completed prior to vessel leaving port and confirm ARPA are present and operational. Bridge Logs confirm ARPA is used during the Otway Basin 3D MC MSS.	Vessel Master Party Chief
	EPS 252: Qualified crew maintain 24/7 watch-keeping during the survey in compliance with the STCW Convention. Watch keeping duties includes monitoring of vessel position (radar and plotter) and water depth at all times during seismic acquisition.	Bridge logs verify watch has been undertaken during the Otway Basin 3D MC MSS.	Vessel Master Party Chief
	EPS 253: Watch keepers are qualified in accordance with STCW95 (or equivalent).	Procurement process includes requirement for Contractor to review/provide qualifications/training of crew members. Induction records outline qualifications/training of all crew members.	VOC Vessel Master
Vessels over 400 gross registered tonnage hold an approved and tested SOPEP, with crew trained in its implementation.	**EPS 254**: SOPEP formulated, known to all staff and kept up to date onboard the vessels so that in the event of a collision where hydrocarbons are released there is a plan in place to contain or clean-up.	Pre-mobilisation audit and inspection prior will confirm vessels holds an up-to-date SOPEP. Induction records show content of induction meeting and participation of crew.	Vessel Master. Party Chief SEA CSR
	EPS 255: Prior to the commencement of the Otway Basin 3D MC MSS operations, the SOPEP will be tested including testing of communications and a vessel-based drill in hydrocarbon spill response.	Induction records and bridge logs confirm testing of SOPEP has occurred and drills have been carried out.	Vessel Master. Party Chief.
	EPS 256: The Vessel Master will authorise actions in accordance with the vessel specific SOPEP and survey specific SOPEP to avoid, and where avoidance is not possible, minimise the escape of hydrocarbons.	Incident Report from a hydrocarbon spill response will confirm whether SOPEP has been followed.	Vessel Master. Party Chief.
	EPS 257: Notification procedures will be implemented, including AMSA and regulatory agencies, including: • AMSA report notification; • NOPSEMA reports; • Regulatory agencies (including DNP); • TGS incident report; and • Pollution report (**POLREP**).	In event of vessel collision/sinking and release of MDO all appropriate forms will be completed and submitted to relevant authorities	TGS VOM Vessel Master.
In the event of a spill to the marine environment, the OPEP will be implemented.	**EPS 258**: The Vessel Master will authorise actions in accordance with the vessel specific SOPEP and the survey specific OPEP to avoid, and where avoidance is not possible, minimise the escape of hydrocarbons.	Incident Report from a hydrocarbon spill response will confirm whether OPEP has been followed	Vessel Master
	EPS 259: MDO is the primary fuel for vessels associated with the Otway Basin 3D MC MSS. No HFO powered vessels will be used.	Bunker note shows MDO utilised.	Vessel Master. Party Chief.

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
Vessels will only utilise MDO. Vessel fuel to be stored in compartmentalised and/or multiple separate onboard fuel tanks.	**EPS 260**: Fuel tanks onboard the vessels will be compartmentalised or consist of multiple smaller tanks throughout the vessel.	Pre-mobilisation audit and inspection prior to beginning of survey will confirm the vessel's fuel storage system.	Vessel Master. Party Chief.
Refuelling will occur away from the Zeehan AMP and Nelson AMP.	**EPS 261**: Refuelling is not undertaken within the sensitive areas as shown in **Figure 92.**	Bridge logs show refuelling undertaken outside of sensitive areas	Vessel Master. Party Chief SEA CSR
	EPS 262: Shape files will be loaded onto the survey vessels' navigation system outlining exclusion areas within which refuelling operations cannot occur	Exclusion polygons on survey vessel's navigation system.	Vessel Master. Party Chief SEA CSR
Appropriate use of radio communication at sea.	**EPS 263**: The survey vessels will have the appropriate communication equipment onboard and will be contactable and also able to communicate with other vessels by radio at all times (i.e. VHF and SSB radio).	Bridge Logs confirm VHF and SSB radio communications are always available.	Vessel Master. Party Chief
Utilising accurate weather forecasting information for planning operations.	**EPS 264**: Survey vessels, as well as onshore project team, to receive wind, wave and current information for the OA four times daily from subscription service.	Copies of the forecasts will be included with the daily reports/logs and kept on file.	Vessel Master EA TGS VOM
Contract in place with appropriate service provider to initiate real-time modelling in case of a spill.	**EPS 265**: Prior to the commencement of the Otway Basin 3D MC MSS, TGS will secure services (signed contract) with a third party for provision of real-time modelling of a hydrocarbon spill if and when required	Service contract in place prior to commencement of the survey.	TGS VOM.
In case of a spill <10m^3, TGS will implement relevant Type I Operational Monitoring.	**EPS 266**: If health and safety requirements permit, the Support Vessel assisting the Seismic Vessel will be used in the monitoring of any hydrocarbon spill.	Incident report provides details on operational monitoring undertaken.	Vessel Master. Party Chief VOC TGS VOM
Type II Scientific Monitoring undertaken (informed by updated NEBA/SIMA) in case of spill if real-time modelling shows the spill will impact land, in consultation with the CA.	**EPS 267**: Prior to the commencement of the Otway Basin 3D MC MSS, TGS will secure services (signed contract) with a third party for standby services in order to undertake Type II scientific monitoring as specific within the OPEP, should a hydrocarbon spill reach the shoreline,	Service contract in place prior to commencement of the survey.	TGS VOM
Hydrocarbon spill response training and competencies will be maintained throughout the Otway Basin 3D MC MSS to avoid unplanned environmental impacts due to human error.	**EPS 268**: Prior to the commencement of the Otway Basin 3D MC MSS an audit will be conducted to ensure all staff are trained and inducted satisfactorily to ensure they are competent in responding to a hydrocarbon spill.	Pre-mobilisation audit results confirm inductions have been completed. Induction and daily records confirm training and induction has been carried out and crew present.	Vessel Master. EA SEA CSR
AIS transponders fitted to survey vessels and tail buoys.	**EPS 269**: Vessels and associated survey equipment (e.g. tail buoys) will have correctly fitted and functioning AIS transponders.	Pre-mobilisation audit and inspection prior to beginning of survey confirms correct operation of all AIS transponders for both transmitting and receiving.	Vessel Master. Party Chief SEA CSR
All crew will participate in the vessel and environmental induction prior to the commencement of operations.	**EPS 270**: All crew will participate in a vessel and environmental induction prior to the commencement of the survey, or on each crew change.	Induction records show content of induction meeting and participation.	Vessel Master. Party Chief. EA
Spill response equipment will be available and maintained onboard each vessel and located in close proximity to hydrocarbon areas and crew onboard will be trained in how to respond to any incident utilising the response equipment available.	**EPS 271**: Spill response equipment will be available and maintained/re-stocked onboard each vessel and located in close proximity to hydrocarbon areas. Crew will be trained in using response equipment.	Inspection records confirm equipment is fit-for-purpose and records any re-stocking of supplies as required.	Vessel Master. Party Chief

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
Undertake hydrocarbon spill modelling prior to EP submission.	**EPS 272**: Hydrocarbon spill modelling will be used to guide the risk assessment of the EP.	Spill modelling incorporated into EP.	TGS VOM
A communications protocol will be in place between the survey vessels and other relevant persons (e.g. commercial fishers known to utilise the OA, oil and gas operators), to actively manage concurrent activities.	**EPS 273**: Pre-survey consultation with relevant persons, confirming the Otway Basin 3D MC MSS will proceed, no less than four weeks before operations commence.	Documentation of consultation and consultation log demonstrate compliance.	TGS VOM EA
	EPS 274: Onshore personnel (EA) will communicate any updates determined through the continuing consultation process to the Vessel Master, where they have the potential to impact the Otway Basin 3D MC MSS and/or relevant persons.	Documentation of consultation and consultation log demonstrate compliance. Forms part of continuing consultation strategy.	EA Vessel Master
	EPS 275: Relevant persons will be notified following the conclusion of the survey as per the following Post-Activity Notifications: • All relevant persons – relevant time post completion; • AMSA – relevant time post completion; • NOPSEMA – 10 days post completion advising the completion of the Seismic Survey; and • NOPSEMA – As soon as practicable advising that all of the activities and obligations covered under the EP have been completed.	Documentation of consultation and consultation log demonstrate compliance.	TGS VOM EA
	EPS 276: A 48-hour 'look-ahead plan' will be provided to relevant persons (who register for the service) identified throughout the relevant persons consultation process, detailing the survey activities over the next 48 hours. The 48-hour look-ahead plans will be updated and issued every 24 hours and distributed to relevant persons via email.	Documentation of consultation, consultation log and issuing of weekly and 48-hour look-ahead plans demonstrate compliance. Forms part of continuing consultation strategy.	TGS VOM EA CSR Vessel Master
Notification to the AHO for the publication of a Notice to Mariners of survey presence and towed array, no less than four weeks before operations commence.	**EPS 277**: A Notice to Mariners will be published and distributed by the AHO under the Navigation Act 2012, informing other marine users of the Otway Basin 3D MC MSS, no less than four weeks before operations commence.	Record of Notice to Mariners.	TGS VOM EA
	EPS 278: Should any changes occur the survey acquisition plan throughout the duration of the Otway Basin 3D MC MSS, all Notice to Mariners will be updated as soon as reasonably practicable.	An updated Notice to Mariners will be issued.	TGS VOM EA CSR Vessel Master
Notification to the JRCC for the promulgation of navigational warnings (i.e AUSCOAST warnings)	**EPS 279**: The JRCC will be contacted 24 – 48 hours prior to the commencement of survey operations for issuing of radio navigation warnings.	Record of notification to JRCC.	TGS VOM EA
Notification to the DNP in the event of an oil spill.	**EPS 280:** The DNP will be verbally notified in the event of an oil spill from any vessel associated with the Otway Basin 3D MC MSS as soon as possible. This will be fulfilled through notification to the Marine Park Compliance Duty Officer (0419 293 465) and notification will include titleholder details, time and location of the incident, proposed response arrangements and locations as per the OPEP, and contact details for the response.	Record of notification to DNP through the Marnie Park Compliance Duty Officer.	TGS VOM EA
At least one Support Vessel will accompany the Seismic Vessel when in operation and when safe to do so (e.g., outside of inclement weather periods), to manage interactions with other marine users.	**EPS 281**: The support vessels will manage vessel interactions through travelling between and maintaining communications with any third-party vessels in the OA..	Bridge logs verify support vessels have successfully communicated with all third-party vessels encountered in the OA.	Vessel Master

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
Seismic survey vessel contractor procedures include requirements to be implemented during refuelling operations, including: • A completed Permit to Work; • A JSA implemented for bunkering operations; • Visual monitoring of gauges, hoses, fittings; • Sea surface bunkering; • Hose checks prior to commencement; • All crew are spill response trained; and • Spill response equipment is nearby, easily accessed and fully stocked.	**EPS 282**: Each vessel will carry out refuelling and bunkering in accordance with a vessel-specific refuelling and bunkering procedure which includes the following minimum requirements: • A completed Permit to Work; • A JSA implemented for bunkering operations; • Visual monitoring of gauges, hoses, fittings prior to any refuelling or bunkering activity; • Sea surface bunkering; • Hose checks prior to commencement; • All crew are spill response trained; and • Spill response equipment is nearby, easily accessed and fully stocked.	Pre-mobilisation audit confirms refuelling and bunking procedures are in place. Audits/inspection records confirm refuelling and bunkering is being performed in compliance with the vessel-specific refuelling and bunkering procedures.	Vessel Master. Party Chief SEA CSR
	EPS 283: Vessel crew are to maintain constant surveillance and communication while refuelling.	Bunker note provides details on PTW, JSA and bunkering procedures undertaken.	Vessel Crew
Dry-break couplings will be installed on refuelling hoses.	**EPS 284:** Dry-break couplings will be installed on refuelling hoses	Pre-mobilisation audit and inspection prior to beginning of survey will confirm.	Vessel Master Party Chief
At sea refuelling operations will only take place during daylight hours and within strict weather limit guidelines.	**EPS 285:** Refuelling operations will only take place during daylight hours and within strict weather limit guidelines	Bunker note provides details on time of day and weather during refuelling operations.	Vessel Master.

8.3.9 Vessel Collision, Sinking, and Bunkering and Associated Hydrocarbon Spill Impact and Risk Summary

Based on the discussions above, including the potential impacts on the environment and the associated controls measures to be implemented, the residual risk of vessel collision/sinking/bunkering incidents and associated hydrocarbon spill is considered to be **Low**.

The risks of a vessel collision occurring are reduced in a number of ways, including the adherence to legislative requirements and industry best practice, along with operating conditions (such as vessel operating at slow speeds). Consequently, it is considered that the environmental impacts and risks on the marine environment and receptors arising from a vessel collision/sinking/bunkering incident and associated hydrocarbon spill are reduced to **ALARP**.

In accordance with the acceptability requirements prescribed in **Section 6.4**, the suite of control measures are considered appropriate to manage the risks and impacts arising from a vessel collision/sinking/bunkering incident and associated hydrocarbon spill during the Otway Basin 3D MC MSS on all receptors to an **Acceptable Level**.

8.4 Hydrocarbon Spill Response

8.4.1 Description of Source of the Impact and Risk

In the unlikely event that a hydrocarbon spill occurs within the marine environment from a vessel associated with the Otway Basin 3D MC MSS, several spill response options can be initiated for a clean-up response.

Table 129 provides an overview of the response options available with an assessment on the advantages and disadvantages of each option, and their appropriateness for use if a spill occurred during the Otway Basin 3D MC MSS.

Table 129 Assessment of Spill Response Options

Response Option	Advantages of use	Disadvantages of use	Appropriateness of use
Source control (securing cargo / trimming).	Reduction in volume of MDO entering the marine environment.	No disadvantages identified.	This response option is suitable to both Level 1 and Level 2 responses and will be adopted in accordance with the SOPEP onboard the vessels. In the event of a fuel tank rupture, or hydrocarbon storage spill occurring, cargo of the affected tank/storage containers is to be secured by any available means, including transfer to another storage area, another vessel or through pumping in water to create a water cushion. Trimming the vessel may also be used to avoid further damage to intact tanks. These actions will minimise the volume of MDO spilled.
Natural weathering (monitor and evaluate – vessel/aerial surveillance and trajectory modelling).	Provides valuable information for situational awareness to inform response options. Surveillance results can also be used to assist in escalating or de-escalating response strategies as required.	Does not directly reduce potential impacts from the spill. Potential increase in the vessel/aviation activity in the area resulting in increased disturbance to fauna, including increased risk of collisions.	Vessel surveillance will be done for level 1 and level 2 spills using available vessels on scene, such as the Support Vessel, for opportunistic surveillance operations. However, priority for human health and safety will take place should a significant vessel casualty occur. TGS will have a contract in place with an appropriate service provider to initiate real-time modelling in the case of a spill. These modelling outputs can be used to guide appropriate response options. Monitoring requirements and approach will be assessed by the relevant Controlling Authority.
Physical break-up (vessel prop-washing).	Enhances natural degradation processes through the water column.	Increased vessel activity – additional noise, light, and atmospheric emissions. Increased health and safety risks from the presence of additional vessels.	This response option may be utilised during the Otway Basin 3D MC MSS.

Response Option	Advantages of use	Disadvantages of use	Appropriateness of use
		Potential for reduced evaporation of MDO by entraining it into the water column.	Vessel prop washing promotes entrainment within the water column and reduces potential evaporation, potentially keeping the substance in the water for longer periods. However, this option would only be undertaken if requested by the Controlling Authority, which their decision-making process would be dependent on the spill location and a NEBA.
Application of dispersants.	No advantages identified for MDO as it is not a persistent hydrocarbon. MDO has a high natural dispersion rate in the marine environment.	Additional release of chemicals into the marine environment that may have toxic effects on marine fauna.	This response option is not recommended for the Otway Basin 3D MC MSS as it is not beneficial for reducing the net environmental impact of a MDO spill. It has a low probability of increasing the dispersal rate of the spill whilst introducing more chemicals into the marine environment.
Contain and recover (booms and skimming).	MDO potentially removed from the environment. Reduces chances for fauna to become oiled.	Use is restricted by surrounding weather conditions – i.e. in rough weather conditions, booms and skimmers will not work. Increased vessel activity – additional noise, light, and atmospheric emissions. Very labour intensive with an increased volume of waste generated.	This response option is not recommended for the Otway Basin 3D MC MSS as the fast-spreading rates of MDO and the low viscosity will cause the slick to break-up and disperse quickly resulting in a reduced ability to contain and recover the MDO from the ocean.
Protect and deflect (booms etc.).	MDO potentially removed from the environment. Reduces chances for shoreline fauna to become oiled.	Increased activity – additional noise, light, and atmospheric emissions. Very labour intensive with an increased volume of waste generated. Potential additional damage to intertidal and benthic habitats from equipment.	This option is not recommended for the Otway Basin 3D MC MSS as MDO is not expected to be persistent and corralling of MDO is generally not effective. Tidal flushing and bioremediation are expected to be sufficient in the worst-case scenarios to prevent any significant environmental impact.
Shoreline clean-up (physical removal, surf washing, flushing, natural dispersion).	MDO potentially removed from the environment. Reduces chances for shoreline fauna to become oiled.	Increased activity – additional noise, light, and atmospheric emissions. Very labour intensive with an increased volume of waste generated. Potential damage to sensitive shoreline species. Weather dependant.	This option is not recommended as it is an intrusive response that requires careful site-specific planning in order to reduce secondary impacts of beach erosion and spreading oil beyond shorelines.

Response Option	Advantages of use	Disadvantages of use	Appropriateness of use
			This response has the potential to cause more harm due to secondary disturbance compared to the initial potential light oiling. Therefore, if light shoreline contact occurs, TGS considers that any onshore response options would best occur under the National Plan.
Oiled Wildlife Response (capture and rehabilitation).	Aids recovery of oiled wildlife.	Increased activity – additional noise, light, and atmospheric emissions. Approaching marine fauna could flee and dive into spilled MDO as a result of activity. Pre-emptive capture may result in reduced survival.	Undertaking this response option has the potential to result in more harm if poorly executed. Activities such as hazing (dispersing) of birds will not be undertaken given the low likelihood of a spill of a size presenting a significant risk of oiling wildlife unless at the direction of, and under direct supervision of trained personal from the Controlling Authority. Capture and rehabilitation may be undertaken under the National Plan.

The activities associated with a response to a hydrocarbon spill introduce further risks to marine fauna and flora, including:

- Increased disturbance of avifauna (both shore and sea birds) and marine mammals;
- Increased risk of vessel strikes with an increased number of vessels in the area conducting the response;
- Potential inclusion of additional chemical agents into the marine environment (i.e. dispersants);
- Potential physical damage to habitats from deployment of booms in the intertidal zone; and
- Potential damage to intertidal habitats from trampling (via foot or vehicles), removal of oiled sediment, chemical control agents and dispersants.

8.4.2 Evaluation of Known and Potential Impacts and Risks to Environmental Receptors

Using the information presented in **Section 4** to **Section 5**, the impact and risk assessment has been undertaken for those receptors determined to be relevant to the activity as listed in **Table 130**.

Table 130 Environmental Receptors Assessed

Receptor	Section reference
Seabirds and shorebirds	**Section 8.4.2**
Marine mammals	
Relevant persons (marine shipping, commercial fisheries, recreational users)	
Benthic habitats (intertidal and shoreline)	
Seabirds and shorebirds	

Undertaking clean-up activities have the potential to disturb the physical environment and marine/coastal habitats and fauna through the use and operation of vehicles, personnel and other necessary equipment. These disturbances can also cause impacts to cultural and amenity values.

Each of the potential response options has been assessed within **Table 129** which includes the potential disadvantages associated with each option, including those potential impacts on the environment, including:

- Increase in the vessel/aviation activity in the area, resulting in increased disturbance to fauna, including additional risks of collisions;
- Additional noise, light and atmospheric emissions causing disturbances to fauna and other users of the marine environment (tourism and recreation, cultural heritage etc.);
- Increased health and safety risks from the presence of additional vessels; and
- Potential damage to sensitive shoreline species from shoreline clean-up.

To reduce the potential impacts from response options, the potential response actions will be based on a NEBA approach which considers the advantages and disadvantages of the different spill response options to determine if there would be a net environmental benefit resulting from the implementation of a particular response.

NEBA and SIMA are commonly used globally for evaluating the potential benefits versus impacts of implementing a pre-defined spill response strategy. The purpose is to identify the most appropriate response strategy(ies) which can be implemented under real-time factors influencing the spill dynamics (location, amount, prevailing weather conditions etc). It can also be a rapid decision-making tool employed by the Controlling Authority under time constraints.

The following is a summary of steps normally used by the Controlling Authority to conduct a NEBA/SIMA for a Level 2 (summarised from IPIECA (2016)):

- Compile and evaluate data for relevant spill scenarios (oil properties, situational awareness, oil spill trajectory modelling, environmental sensitivities, identification of resources at risk, and determination of feasible response options);
- Predict outcomes/impacts for the no intervention for the 'no intervention' (or 'natural attenuation' / unmitigated spill impact) option as well as the effectiveness (i.e. relative mitigation potential) of the feasible response options for each scenario;
- Balance trade-offs by weighing and comparing the range of benefits and drawbacks associated with each feasible response option, including no intervention, for each scenario; and
- Select the best response option/s to form the strategy for each scenario, based on the combination of techniques that will minimize the overall ecological, socio-economic and cultural impacts and promote rapid recovery, and maximise potential for environmental protection

NEBA takes into account the hydrocarbon type, the sensitivities within the wider area of the spill, and the potential impacts, both positive and negative, of the proposed response strategy. This analysis is used for the preliminary assessment to determine the level of spill response required, and to assist in the prioritisation of response actions. During a spill event, the NEBA will be revisited regularly by the Controlling Authority (and subject matter experts as required) as more information becomes available on weather conditions relevant to at spill location, the spill trajectory and locations of sensitive receptors in the surrounding areas.

Initial response to an oil spill incident will be undertaken by the relevant Vessel Master. For vessel oil spill incidents, the Vessel Master will act in accordance with the relevant SOPEP where applicable. Oil spills from vessels are categorised in two levels:

- **Level 1 Vessel Spill** - Initial activations for a Level 1 spill are based on a spill incident that is small in scale/volume (up to 10 m^3), will not have an adverse effect on the public or the environment and can be controlled by the use of resources typically available aboard the vessel without the need to mobilise an Incident Management Team or other external assistance. Spills that require this level of response may arise from blown hydraulic hoses, dropped or leaking drums of fuel or lubricant or minor refuelling accidents; and

- **Level 2 Vessel Spill** - Level 2 spills are those that require external assistance and resources to mitigate impacts from a larger spill (up to 1,000 m^3) and will involve response activation through additional support teams. The worst-case vessel spill scenarios during the activities fall into this category which include a vessel refuelling incident and a fuel tank rupture incident.

The residual risk to environmental receptors from the response methods utilised to clean up a hydrocarbon spill have been assessed as **Low** (*Minor* x *Remote*).

8.4.3 Decision Context

The decision context for the hydrocarbon spill response has been assessed as Type A given the predicted impacts and risks are well understood and uncertainty is minimal, with little or no interest from relevant persons.

8.4.4 Identification of Control Measures, Residual Risk Assessment and Demonstration of ALARP

Control measures that have been considered for the Seismic Survey to manage the potential risk/impacts associated with hydrocarbon spill response options to ALARP are listed in **Table 132**. TGS has considered a number of control measures to determine the benefits of their implementation towards risk reduction based on a Hierarchy of Controls methodology (**Table 131**). The control measures that will be adopted are those that have been assessed and characterised as effective and practicable to implement.

Table 131 Hierarch of Control Measures for Hydrocarbon Spill Response

Eliminate	A significant response to a hydrocarbon spill is required; however, those methods that increase the risks to the environment have been eliminated (such as releasing a chemical dispersant) as the benefit of using these methods does not outweigh the risks associated with their use.
Substitute	There are no suitable substitutes for the response to a hydrocarbon spill event. The most applicable response has already been determined, using the NEBA approach (**Table 132**).
Reduce	The methods will also be analysed in consultation with the Controlling Authority through a NEBA process to ensure the most appropriate method is used in responding to a spill event. Any reduction in the impacts of a response to a hydrocarbon spill will be weighed against the net environmental benefit achieved.
Mitigate	Control measures have been assessed within **Table 132** to mitigate impacts associated with the nominated response/s to a hydrocarbon spill to **ALARP** and **Acceptable Levels**. Those measures which are appropriate and are not impractical or unfeasible will be implemented during the Otway Basin 3D MC MS.

Table 132 Assessment of Control Measures for Hydrocarbon Spill Response

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Legislative Requirements:			
The Otway Basin 3D MC MSS will be undertaken in accordance with the approved EP.	P = Yes E = Effective	All vessels undertaking an offshore activity in waters between 3 and 200 NM must undertake that activity in line with an approved EP. The approved EP outlines the measures that will be taken to ensure that environmental effects from the activity will be reduced to **ALARP** and **Acceptable Levels**, including the management of routine permissible waste discharges.	Yes
Vessels >400 GRT (MARPOL 73/78 Annex I) hold an approved and tested SOPEP and crew are trained in its implementation. The SOPEP will be implemented for first strike response to level 1 and level 2 spills.	P = Yes E = Effective	In accordance with the requirements of Annex I of MARPOL 73/78, vessels will have a SOPEP. By ensuring a SOPEP is in place for the vessel, the likelihood of a spill entering the marine environment is reduced. TGS will implement the response strategy in accordance with the SOPEP, and also in line with relevant legislation and industry standards.	Yes
Good Industry Practice:			
Operational monitoring will be undertaken in order to inform and update the Controlling Authority about the behaviour of the spill.	P = Yes E = Effective	Operational Monitoring (such as using the Support Vessel to monitor the spill) will be undertaken in the unlikely event of a hydrocarbon spill to provide up-to-date information on the fate of any hydrocarbon spill in the water. This monitoring will allow appropriate response options to be established with the Controlling Authority and undertake appropriate NEBA analysis to reduce the potential impacts from responding to a hydrocarbon spill. Good industry practice, environmental benefit outweighs additional cost.	Yes
Contract in place with appropriate service provider to initiate real-time modelling in case of a spill.	P = Yes E = Effective	Undertaking real-time modelling will provide assurances that response options can be tailored to the specific spill situation. The modelling will be used to predict the potential beaching locations (if any exist) and inform the responders in order to assist in reducing the potential impacts from the response options if possible. Good industry practice, environmental benefit outweighs additional cost.	Yes
Hydrocarbon spill response training and competencies will be maintained throughout the Otway Basin 3D MC MSS to avoid unplanned environmental impacts due to human error.	P = Yes E = Effective	Ensuring all crew have appropriate training is vital in responding to a hydrocarbon spill and ensuring that impacts to the environment are not exacerbated through the response options themselves. Drills will also be undertaken to ensure all crew are competent in responding to spills under the vessel specific SOPEP. These drills will be conducted at regular intervals to ensure competencies are maintained for the duration of the Otway Basin 3D MC MSS. Good industry practice, environmental benefit outweighs additional cost.	Yes
A hydrocarbon spill will be immediately reported from the TGS onboard representative to TGS in Perth to ensure all notifications are provided as per **Section 10.10.6.3.**	P = Yes E = Effective	Notifications will ensure quick and appropriate response to a spill scenario and will be in accordance with SOPEP and in accordance with relevant legislation and industry standards, ultimately informing the response options and allowing a NEBA to be undertaken. Good industry practice, environmental benefit outweighs additional cost.	Yes
Fishing industry and other relevant persons will be notified in the event of a spill. Notification to the DNP in the event of an oil spill.	P = Yes E = Effective	Communication with relevant persons allows those potentially affected by a hydrocarbon spill to plan activities in a manner that reduces the risk of interactions. The DNP should be made aware of unplanned events such as an oil spill which occurs within an AMP, or is likely to affect any AMPs, as soon as possible. Parks Australia plays a role in the National Plan for Maritime Environmental Emergencies. The DNP should be notified through notification to the Marine Park Compliance Duty Officer (0419 293 465). Notification should include: titleholder details, time and location of the incident, proposed response arrangements and locations as per the OPEP, and contact details for the response. Good industry practice, environmental benefit outweighs additional cost.	Yes
NEBA to be conducted prior to response actions.	P = Yes E = Effective	Response actions will be based on a NEBA approach which considers the advantages and disadvantages of the different spill response options to determine if there would be a net environmental benefit resulting from the implementation of a particular response. Good industry practice, environmental benefit outweighs additional cost.	Yes

Control Measure	Practicability/ Effectiveness	Justification	Will it be adopted?
Alternatives/Substitutes Controls Considered:			
Eliminate vessels to avoid spill, and hence avoid impacts from response options.	P = No E = Very Effective	There are no practicable methods for undertaking the Otway Basin 3D MC MSS without the use of specialist survey vessels. Costs would be disproportionate to the benefit that may be gained.	No
Additional Control Measures Considered:			
Dedicated spill response vessel and resources on standby.	P = No E = Effective	The option of having a dedicated spill response vessel on standby for the survey was discounted on the basis that the cost would be grossly disproportionate to any reduction in risk (which is already determined to be Low), particularly as the expected behaviour of an MDO spill would limit the effectiveness of on-water response options. Additional vessels could also increase the risk of interference and potential for collisions.	No
Pre-activity monitoring program and development of detailed Type II Monitoring Plan.	P = No E = Fairly Effective	TGS do not consider it practicable to undertaken monitoring or development of a detailed Type II monitoring program in response to the unlikely risk of a hydrocarbon spill. The characteristics of MDO will likely result in rapid dispersion. In addition, TGS will implement various controls that will reduce the risks of vessel collision; implementation of SOPEP to prevent loss of an entire tank contents. Costs would be disproportionate to the benefit that may be gained.	No
Additional response equipment on board the Support Vessel.	P = No E = No	It is not reasonable for additional resources to be provided and maintained on the Support Vessel in the unlikely event of a spill. The Support Vessel is already equipped to best practice levels and supported by the National Plan. In order to carry the additional equipment (such as booms), additional vessels would be required. Costs would be disproportionate to the benefit that may be gained.	No
Arrangements for aerial monitoring.	P = No E = No	It is not considered that these resources could be mobilised faster than what can already be achieved under the National Plan arrangement. Costs would be disproportionate to the benefit that may be gained.	No
Residual Risk of Impact (Receptor)	**Consequence**	**Likelihood**	**Risk Ranking**
Seabirds and shorebirds	Minor	Remote	Low
Marine mammals	Minor	Remote	Low
Relevant persons (marine shipping, commercial fisheries, recreational users)	Minor	Remote	Low
Benthic habitats (intertidal and shoreline)	Minor	Remote	Low
ALARP Statement			
The decision context has been assessed as Type A and the overall residual risk has been determined to be **Low**. TGS considers the adopted control measures are sufficient to minimise the risk of impacts from a hydrocarbon spill response are appropriate to the localised nature and small scale of the predicted environmental impacts associated with a spill response. The proposed control measures have been developed in accordance with Good Industry Practice, taking into account the specific environmental, social, economic and cultural characteristics of the OA and predicted impacts to other marine users. Additional control measures have been considered as part of the assessment process; however, it was considered that they did not provide any further environmental benefit or were not reasonably practicable to implement. Therefore, the predicted impacts to receptors from a hydrocarbon spill response are reduced to **ALARP**.			

8.4.5 Impact and Risk Acceptability

Table 133 Demonstration of General Impact and Risk Acceptability for Hydrocarbon Spill Response

Criteria for Acceptance	Acceptability Summary
Residual Risk Ranking	The residual risk has been determined to be Low.
Ecologically Sustainable Development	The management of the risk proposed by TGS associated with the response to a hydrocarbon spill can be carried out in compliance with the five principles of ESD as defined within the EPBC Act. These principles have been considered as part of the development of the EP and risk assessment process. The assessment has not identified any adverse impacts to the principles of ESD, with no threats of serious or irreversible damage, no impacts to biological diversity and ecological integrity, no degradation of inter-generational equity, or negative effects on the social and economic integrity in the short or long-term.
TGS Internal Context	The proposed management of the risks of streamer loss and its associated impacts will be informed by TGS's Non-Routine Equipment Recovery Procedures and Environmental and QHSE Policy commitments of: • Protecting the environment; and • Conducting operations in an environmentally sustainable and responsible manner.
Existing Environmental Context	Following implementation of control measures the potential risk of any impacts occurring to water quality, and marine flora and fauna in the surrounding marine environment from the response to a hydrocarbon spill is unlikely. It is also highly unlikely to pose a risk to the management objectives for protected or sensitive areas (i.e. AMPs, KEFs etc.), habitats (i.e. subtidal), fauna and flora present. No impacts are predicted on the existing environment within or surrounding the OA from a response to a hydrocarbon spill. Due to the open ocean nature of the OA, in the unlikely event that a spill occurs, the MDO would undergo rapid and significant dilution as soon as it entered the receiving environment, and concentrations would quickly dilute and disperse. The resulting response to a spill of this nature would be to primarily monitor and observe the spill, with the resulting impacts of such a response principally being from additional vessels within the OA. The proposed control measures provide appropriate protection to the marine environment from the response to a hydrocarbon spill, and from a detailed assessment process it is considered that any further/alternative control measures would give very little or no further protection from the response to a hydrocarbon spill.
External Context – Management Plans, Species Recovery Plans and Conservation Advice	The residual risk of a hydrocarbon spill response has been determined to be Low and will not have a significant impact on a matter of national environmental significance in accordance with EPBC Act Policy Statement 1.1. The OA overlaps with two AMP boundaries (the Zeehan AMP and Nelson AMP), and the EMBA overlaps with a further eight AMPs (the Apollo AMP, Franklin AMP, Boags AMP, Murray AMP, Huon AMP, Tasman Fracture AMP, Beagle AMP, East Gippsland AMPs). Oil pollution response, environmental monitoring and remediation activities can be undertaken with IUCN Category VI zones (multiple use zones that include all AMPs in the OA and overlapping with the EMBA), when undertaken in accordance with a NOPSEMA approved EP that has met all required environmental management arrangements for the activity covered in the class approval. However, any oil pollution incident that may affect other IUCN category zones requires prompt consultation with the Director of National Parks.
Social Acceptance – Relevant Persons Expectations	Although concerns were raised during consultation with relevant persons around the potential effects of an oil spill (see **Section 8.3**), no concerns about the impacts from responding to a hydrocarbon spill were raised and as such no additional control/mitigation measures were expected or put in place. However, the Director of National Parks noted that they are to be made aware of oil/gas pollution incidences which occur within a marine park, or are likely to impact on a marine park, as soon as possible. To ensure this expectation is met, a corresponding control measure is proposed to be implemented, as outlined in **Table 134.** As such, the environmental impacts relating to responding to a hydrocarbon spill were considered to be at a socially **Acceptable Level**.
External Context – Commonwealth and State Legislative Criteria	The proposed control measures for responding to a hydrocarbon spill during the Seismic Survey are consistent with the following relevant legislation: • Australian Maritime Safety Authority Act 1990; • International Convention on Oil Pollution Preparedness, Response and Cooperation 1990; • United Nations Convention on the Law of the Sea 1982; • International Convention for the Prevention of Pollution from Ships 1973; • Protection of the Sea (Civil Liability for Bunker Fuel Pollution Damage) Act 2008; • EPBC Act; • EPBC Regulations; and • Protection of the Sea (Prevention of Pollution from Ships) Act 1983 and its associated Marine Order 91 (Marine Pollution Prevention – Oil).
Industry Best Practice	The NEBA controls are in line with industry best practice with the depth of controls provided considered to reflect best practice and reasonable for the nature and scale of the activity. The APPEA Code of Environment Practice objectives with respect to reducing the impact from events such as spills to a level which is **ALARP** and acceptable are met by demonstrating the adoption of appropriate management procedures for the activity and having an appropriate emergency response plan. The IAGC Environmental Manual for Worldwide Geophysical Operations sets objectives in relation to hazardous materials for spill leak response which is met by the Otway Basin 3D MC MSS.
ALARP	Complete elimination is not possible as the response is required in the event of a hydrocarbon spill.

Criteria for Acceptance	Acceptability Summary
	Based on the assessment above, including consideration of the potential impacts on the environment and the associated controls measures to be implemented, the residual risk to the marine environment and associated receptors from the response to a hydrocarbon spill is considered to be **Low** and to **ALARP**. Therefore, the potential risk of impacts occurring from the response to a hydrocarbon spill during the Seismic Survey is considered to be at an **Acceptable Level**.

Acceptability Statement
Impacts and risks classified as Type A are considered acceptable if the requirements in **Table 51** can be demonstrated and it can be determined that the predicted levels of impact and/or residual risk are at or below pre-defined acceptable levels for that impact or risk, including those described in **Table 52**. Based on the above evaluation, the potential impacts from a hydrocarbon spill response meets the requirements of the risk acceptability criteria. The control measures that will be implemented throughout the Otway Basin 3D MC MSS have been developed in accordance with these criteria and are considered appropriate to manage the impacts of a hydrocarbon spill response on all receptors to an **Acceptable Level**.

8.4.6 Environmental Performance

Table 134 Environmental Performance Outcomes, Standards and Measurement Criteria for Hydrocarbon Spill Response

Number	Environmental Performance Outcome		Environmental Performance Standard(s)
EPO 28	No secondary impacts to the marine environment associated with a response to a hydrocarbon spill and all responses will be undertaken in accordance with the vessel SOPEP		**EPS 286** to **EPS 297**
Control Measure	**Environmental Performance Standard**	**Measurement Criteria**	**Responsible Party**
The Otway Basin 3D MC MSS will be undertaken in accordance with the approved EP.	**EPS 286**: The Otway Basin 3D MC MSS may only commence following acceptance of the EP by NOPSEMA.	Pre-mobilisation audit and inspection are completed prior to operations and confirm an accepted EP has been obtained. Audit records verify compliance with the requirements of the EP.	TGS VOM EA
	EPS 287: The Otway Basin 3D MC MSS will be undertaken in accordance with the accepted EP.	Bridge logs verify compliance with the requirements of the EP. Audit records verify compliance with the requirements of the EP.	TGS VOM VOC EA Vessel Master SEA
Vessels >400 GRT (MARPOL 73/78 Annex I) hold an approved and tested SOPEP and crew are trained in its implementation. The SOPEP will be implemented for first strike response to level 1 and level 2 spills.	**EPS 288**: The Vessel Master will authorise actions in accordance with the vessel specific SOPEP and survey specific SOPEP to avoid, and where avoidance is not possible, minimise the escape of hydrocarbons.	Incident Report from a hydrocarbon spill response will confirm whether SOPEP has been followed.	Vessel Master. Party Chief.
Operational Monitoring will be undertaken in order to inform and update the Controlling Authority about the behaviour of the spill.	**EPS 289**: Support Vessel that is associated with the Otway Basin 3D MC MSS will be available as a vessel of opportunity to monitor the spill if safe to do so and where NEBA identifies a net benefit to do so, as agreed with the Controlling Authority.	Incident Report from a hydrocarbon spill response will confirm results of spill monitoring. NEBA Report will outline the results of the monitoring	TGS VOM VOC Vessel Master
Contract in place with appropriate service provider to initiate real-time spill modelling in case of a spill.	**EPS 290**: Prior to the commencement of the Otway Basin 3D MC MSS, TGS will secure services (in the form of a signed contract) with a third party for provision of real-time modelling (dispersion and trajectory) if and when required.	Service contract in place prior to commencement of the Otway Basin 3D MC MSS and provided in pre-mobilisation audit.	TGS VOM
Hydrocarbon spill response training and competencies maintained throughout the Otway Basin 3D MC MSS to avoid unplanned environmental impacts due to human error.	**EPS 291**: Prior to the commencement of the Otway Basin 3D MC MSS an audit is conducted with all maritime crew to ensure all staff are trained and inducted satisfactorily to ensure they are competent in responding to a hydrocarbon spill. This will occur for all new staff joining the vessel during crew changes to ensure full coverage	Pre-mobilisation audit results detail hydrocarbon spill response training and competencies of staff prior to undertaking the Otway Basin 3D MS MSS. Induction and daily records confirm training and induction has been carried out and crew present.	TGS VOM Vessel Master. Party Chief SEA

Control Measure	Environmental Performance Standard	Measurement Criteria	Responsible Party
A hydrocarbon spill will be immediately reported from the TGS onboard representative to TGS in Perth to ensure all notifications are provided as per **Section 10.10.6.3.**	**EPS 292**: Initial SOPEP report requirements will be undertaken and TGS will be immediately notified.	Phone/email records show notification undertaken. Consultation records show notification undertaken.	TGS VOM Vessel Master
	EPS 293: External notifications in the event of a level 1 or level 2 spill will be carried out as per the following reporting schedule: • TGS Project Manager – immediately; • NOPSEMA – verbal notification within two hours; • NOPSEMA – written NOPSEMA Incident Report Form no later than three days after notification; • National Offshore Petroleum Titles Administration – verbal or written incident summary within one day; • Commonwealth Department Climate Change, Energy the Environment, and Water (DCCEEW), Written POLREP notification submitted within 7 days; and • Director of National Parks – as soon as practicable following incident.	Phone/email records show notification undertaken. Consultation records show notification undertaken.	TGS VOM. Vessel Master.
	EPS 294: External notifications in the event of a Level 2 spill will be carried out as per the following reporting schedule: • AMSA – verbal notification as soon as possible, with follow-up written POLREP as soon as practicable; • Transport Safety Victoria – Maritime Safety Victoria unit: (if spill affects VIC state waters) – verbal notification as soon as it is identified that hydrocarbon may enter VIC state waters, with follow-up written POLREP as soon as practicable; • Tasmania Environment Protection Authority (if spill affects TAS waters) verbal notification as soon as it is identified that hydrocarbon may enter TAS state waters, with follow-up written POLREP as soon as practicable; • SA Department of Planning, Transport and Infrastructure (if spill affects SA waters) – verbal notification as soon as it is identified that hydrocarbon may enter SA state waters, with follow-up written POLREP as soon as practicable; • NSW Department of Transport (Maritime) (if spill affects NSW waters) – verbal notification as soon as it is identified that hydrocarbon may enter NSW state waters, with follow-up written POLREP as soon as practicable; • Type II Monitoring Service Provider – verbal notification within two hours with follow-up formal notification if and when a scientific monitoring program initiation criterion is met.	Phone/email records show notification undertaken. Consultation records show notification undertaken.	TGS VOM
Fishing industry and other relevant persons will be notified. Notification to the DNP in the event of an oil spill.	**EPS 295**: Notification with the fishing industry and other relevant persons will be undertaken utilising the same contacts associated with the 48-hour 'look-ahead' plan.	Documentation of consultation. Forms part of continuing consultation strategy.	TGS VOM
	EPS 296: The DNP will be verbally notified in the event of an oil spill from any vessel associated with the Otway Basin 3D MC MSS as soon as possible. This will be fulfilled through notification to the Marine Park Compliance Duty Officer (0419 293 465) and notification will include titleholder details, time and location of the incident, proposed response arrangements and locations as per the OPEP, and contact details for the response.	Record of notification to DNP through the Marnie Park Compliance Duty Officer.	TGS VOM EA
NEBA to be conducted prior to response actions.	**EPS 297**: Response actions will be based on a NEBA approach in consultation with CA.	NEBA Report will show the methodology and results of the NEBA.	TGS VOM

8.4.7 Hydrocarbon Spill Response Impact and Risk Summary

Based on the discussions above, including the potential impacts on the environment and the associated controls measures to be implemented, the residual risk from the response to a hydrocarbon spill is considered to be **Low.**

The suite of control measures to be implemented have been developed in accordance with Industry Best Practice and relevant legislation. Consequently, it is considered that the environmental impacts and risk on the marine environment and receptors arising from a hydrocarbon spill response are reduced to **ALARP**.

In accordance with the acceptability requirements prescribed in **Section 6.4**, the suite of control measures are considered appropriate to manage the risks and impacts arising from a hydrocarbon spill response during the Otway Basin 3D MC MSS on all receptors to an **Acceptable Level**.

8.5 Accidental Release of Hazardous and Non-Hazardous Materials

8.5.1 Description of Source of the Impact and Risk

The survey vessels utilised during the Otway Basin 3D MC MSS will use, store, and/or carry a range of chemicals onboard as part of standard day to day operations. These include paints, hydraulic fluid, cleaning products and other substances. Day-to-day activities will also result in the generation of a range of wastes both solid and liquid, including sewage, bottles, cardboard, paper, cans, domestic garbage and other liquid wastes. Wastes not able to be macerated or incinerated will be stored onboard the vessels for onshore disposal at suitable facilities.

Solid wastes will not be discharged to sea but rather will be stored on board the vessels prior to transfer to a support vessel for onshore recycling or disposal. Where practical, solid waste will be minimised and non-hazardous waste will be either re-used or recycled. Solid waste will be segregated onboard the vessel in specific bins in accordance with the vessel's Waste Management Plan. Bins will be fitted with lids/cargo nets for any waste with the potential to be windblown. All domestic waste discharge will be managed in accordance with the requirements of MARPOL 73/78 and the AMSA Marine Orders made under the Protection of the Sea (Prevention of Pollution from Ships) Act 1983.

Hazardous and non-hazardous materials can be accidentally released to the marine environment through machinery failure, malfunction, or operator error (such as split hydraulic hoses releasing fluids), leaks from containment or inadequate clean-up of hazardous substances (such as following a split container), or if materials are lost overboard during bad weather or while transferring between vessels.

Routine discharges of biodegradable wastes have been assessed in **Section 7.3** and incineration of wastes have been assessed in **Section 7.4.** **Section 8.2** assesses the risks associated with unplanned release of hazardous materials specific to hydrocarbon liquids (spills). These are not considered further within this section. The following section deals with risks and impacts associated with accidental releases of hazardous and non-hazardous materials to the marine environment during the Otway Basin 3D MC MSS.

8.5.2 Evaluation of Known and Potential Impacts and Risks to Environmental Receptors

Using the information presented in **Section 4** to **Section 5**, the impact and risk assessment has been undertaken for those receptors determined to be relevant to the activity as listed in **Table 135**.

Table 135 Environmental Receptors Assessed

Receptor	Section reference
Marine environment quality (water quality)	**Section 8.5.2**
Plankton	
Marine fauna	
EPBC Act listed marine fauna	
Marine protected areas and sensitive areas	

The release of hazardous chemicals/liquid wastes has the potential to reduce water quality to a degree which poses risk to marine receptors. This could impact on marine organisms from plankton through to marine mammals, turtles, fish, and seabirds, either through direct exposure or because of ingesting prey within which toxic substances have bioaccumulated. The potential impacts associated with exposure to (hazardous and non-hazardous) wastes depend on a range of factors, including the toxicity, concentration and phase of the relevant compound and the nature of the exposure scenario itself. The amalgamation of these factors determines whether there is an observable effect, such as toxic, sub-lethal and lethal effects. The volume of hazardous materials that could potentially be released unintentionally from the survey vessels is small and, therefore, is likely to be rapidly dispersed and diluted to a point where concentrations are below levels expected to cause effects to marine organisms. In the event of an onboard spill, it is expected that hazardous waste would be contained on the vessel and cleaned up in accordance with the SOPEP and standard clean-up procedures, decreasing chances of a major release to the receiving marine environment.

Non-hazardous materials such as paper, cardboard, wood and packaging can also potentially cause impacts if accidentally released into the marine environment, including direct physical impacts to marine organisms (strangling, choking) or the benthic environment if materials sink (localised crushing, smothering), or indirect impacts related to a reduction in water quality (e.g. through the breakdown of materials into smaller components and/or leaching of chemicals into the water column).

Ingestion of wastes such as plastics has been identified as a threat within Recovery Plans, Conservation Advice, and Conservation Management Plans for several of the species identified as potentially present within the OA (**Table 32**). Of particular concern is the ingestion of wastes such as plastics by seabirds and marine turtles. Various species of seabird forage within the waters of the OA and wider Otway Basin, with these waters identified as important foraging areas (based on the identification of foraging BIAs) for 24 seabird species (**Table 31**). There are no foraging BIAs identified for marine reptiles within the OA, although loggerhead, leatherback, green, flatback, and hawksbill turtles may utilise waters of the OA.

Due to the offshore nature of the OA, and the localised nature of any unplanned releases, sensitive marine habitats are unlikely to be affected as these exist primarily on the seabed and/or in the nearshore environment. However, the Zeehan and Nelson AMPs and West Tasmanian Canyons KEF lie within the boundaries of the OA and the potential for an accidental release of hazardous and non-hazardous materials within these sensitive areas cannot be completely ruled out.
